V.7

NINIAN NIVEN.

AN

ILLUSTRATED WEEKLY JOURNAL

OF

GARDENING IN ALL ITS BRANCHES.

FOUNDED BY WILLIAM ROBINSON, AUTHOR OF "ALPINE FLOWERS," &C.

THIS IS AN ART
WHICH DOES MEND NATURE: CHANGE IT RATHER: BUT
THE ART ITSELF IS NATURE.—Shakespeare.

VOL. VII.

LONDON:
OFFICE: 37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.
—
MIDSUMMER, 1875.

INDEX TO VOLUME VII.

A.

Abelia triflora, 491
Abies Menziesii, 56
Abutilon Darwinii, 148, 226, 416, 456;
 Duc de Malakoff, 35
Acacia lophantha, outdoor, 200; *Nemu*,
 395; *pubescens*, 34
Acacias, greenhouse, 384
Acacia wood, value of, 471
Acalypha marginata, 456, 521
Acanthoriza Warscewiczii, 481
Acer polymorphum palmatifidum, 452
Acis, species of, 156
 Acland, Sir Thomas, and tree lopping,
 26
Aconitum Napellus, 171
Adiantum Farleyense for hair decora-
 tion, 226; *gracillimum*, 339; *Hender-
 soni*, 456; *Seemanni*, 481; *speciosum*,
 465
Æchmea cœlestis, 452
Ærides odoratum, well-flowered, 500
Æthionema grandiflorum, 500
Agaric, Orange milk, 190
Agapanthus, white flowered, 507, 522
Agave beaucarnea, 456; *Besseriana*
major, 456; (*Fourcroya*) *variegata*,
 456; *marginata*, 456; *marmorata*,
 456; *Pilgrim*, 456; *polyantha*, 456;
pubescens, 456; *salmiana fol. aurea-
 variegata*, 456; *Veitchii*, 456
Ageratum, Tom Thumb, from seed, 200
Agrostis nebulosa for pots, 252
Alamandas as conservatory plants, 317
Alcinous, garden of, 406
 Alfa in Algeria, the, 274
 Allotment gardens, 329
 Allspice, 57
 Almond Peach, 92
Aloe ciliaris, 217; *fruticosa*, 26; *varie-
 gated American*, flowering of, 482
Aloes at Kew, 59; at Sudbury House,
 190, 261
Alonsoa linifolia, 127; *mystifolia*, 124
 Alpines at Easter Duddingston, 457;
 white-flowered, 220
Alsophila australis Williamsi, 456
Alternantheras, propagation of, 319
Alyssum saxatile, 482
Amadou, 112
Amelanchier canadensis, 525
Amaryllids, 193; sowing and growing,
 116
Amaryllis, E. G. Henderson, 170; *Hen-
 dersoni coccinea*, 346, 363
America, early vegetables in, 296
Amherstia nobilis from cuttings, 385
Amygdalus grandiflora, 92
Andromeda floribunda for house decora-
 tion, 370; *Mariana*, 370
Anemone, *fulgens*, 254; *Honerine Jo-
 bert*, 464
Anemones, all the; 423; at Kew, 484
Angræcum sesquipedale, 59
Annuals, select hardy, 281, 290; sow-
 ing, 313; transplanting, 389
Anthurium Scherzerianum, fine, 274;
large-spathed, 317, 318; *two-spathed*,
 481, 507
Aphides, cure for, 261, 312, 327, 485;
 on Cherry trees, 456
 Apple trees, 410; canker in, 376, 396;
 new insect pest of, 234; split by cold,
 342; cordon, 236
 Apples, American Crab, 278; Ash-
 mead's Kernel, 170; in various
 climates, 371; French Paradise, 386;
 good keeping, 378, 508; keeping out
 of doors, 412; russet belts on, 240;
 select, 16, 45; old Nonpareil, 254;
 red-leaf Russet, 62; cider, 450;
 golden, 308; useful, 107
 Apples, grafting, 273; ornamental,
 202
 Apple-blossom maggot, 446, 458; pros-
 pects in Devon, 416
 Approaches, 525
 Apricots, 409; blooming of, 278;
 branches of, dying off of, 295;

seedling, 336, 342; summer treatment
 of, 467
 Aquarium, portable, 329; at Westmin-
 ster, 59
 Aquatic seeds, vitality of, 104
Arabis blepharophylla superba, 416
Aralia japonica, hardiness of, 328;
Guilfoylei, 506
Araucaria, large, 311; at Dropmore,
 124
 Arboretum, Arnold, 84
 Arbor-vitæ, Eastern, 25
 Arbours, rustic, 222, 502
Arbutus Croomei, 55
Aristolochias, 35
Armeria mauritanica, 421
 Arran Isles, flora of, 274
 Artichokes and rheumatism, 168; Globe,
 planting of, 354; Jerusalem, 90;
 spring treatment of, 260
Arum Arisarum, 256
 Ash trees, late leafing of, 491
 Asparagus beds, treatment of, 246, 270,
 281, 398; ditto, after cutting, 514;
 cooking, 470; cutting, 415; in old
 times, 392; oyster bed, 295; varieties
 of, 50; decumbens, 60
 Asphodel, so called, blue, 504, 524
 Asters, open ground, 450; culture of, 528
 Aston, proposed exhibition at, 26
Athyrium, f. f. *apicale*, 456; f. f. *Jack-
 sonia*, 456
Aubretia Eyerii, 336; *Hendersoni*, 484;
purpurea, 373
Aucubas, fertilising, 22, 146, 183; new
 hybrid, 266
Auricula, double yellow, 503
Auriculas, 422; old and new, 480;
 properties of, 289
 Avenues, 471, 473
 Azaleas, *amœna Caldwelli*, 148; perish-
 ing of buds of, 364; bottom-heat for,
 318; hardy, 491; grafting ditto, 233;
 hybrid, 375; top-dressing, 276, 295,
 new, 505

B.

Bactris Gachipaës, 422
 Bagatelle, Bois de Boulogne, 112
Balbisia verticillata, 478
 Balcony gardens, Spanish, 149
 Balsams, culture of, 522
Bambusa viridi glaucescens, 279
 Basket plants, town, 316
Barbe de Capucin, 399
 Bean, French, Osborn's Forcing, 245,
 338, 392, 415; Seville Long-pod, 210,
 245, 254; trial at Chiswick, 135;
 Williams' dwarf French, 102; forcing
 French, 37, 416, 490; ditto at Burgh-
 ley, 436, 438; best dwarf French, 335,
 392; Canadian Wonder, 392; New-
 ington Wonder, 392; Sion House, 392;
 sowing, 345; Haricot, 393; Kidney,
 in small gardens, 416; Scarlet Run-
 ner, 393; ditto, sowing, 368; select,
 357; Beck's Green Gem, 533
 Bedding plants, best varieties of, 172;
 French, 89; propagation of, 71
 Beech trees, Ivy on, 370; notes on, 226
 Bee flowers, 404
 Bees and the Wistaria, 452
 Beet, culture of, 155; Dell's Crimson,
 199; protecting ornamental, 173;
 select, 357
Begonia, *Ascotiensis*, 68; Emperor,
 518; Lapeyrouse, 217; hardiness of,
 89; hardy hybrid, 279; tuberous-
 rooted, 463
 Belgians, new conservatory to be built
 by King of, 26
 Bell, death of Mr. J., 146
Berberis Darwinii, 406
Bergamotte Arsène Sannier, 385
Bertolonia Houtteana, 276, 376, 416
Bertolonia, new, 478
Beschorneria yuccoides, 519
Betula, various species of, 200
 Bindweed, exterminating, 416

Birch, Mountain, 396
 Birches, climbers on, 220; list of, 200
 Bird-scarers, 334, 342
 Bird's nests, artificial, 59, 309
 Birds and fruit-buds, 111; and seeds,
 134; destruction of Crocuses by, 296;
 garden song, 366
 Bladder-nut, 128
Blandfordia princeps, 456
 Blood-louse, 234
Blumenbachia Chuquitensis, 26, 173
 Bog at Glasnevin, 483
 Boilers and furnaces, large, 58; explo-
 sion of gas under, 292, 336, 356; gas,
 212; incrustation of, 493, 496; large,
 95; setting, 138, 313, 354; sunken,
 125, 167, 188, 212, 232, 252, 271; Wat-
 son's portable, 17
 Boldu, 60
 Borage, uses of, 50
 Borders, arrangement of in seasons,
 136; herbaceous, how to plant, 165
 Borecole, dwarf-curved, 268
 Botanical annual, new German, 26
 Botanical nomenclature, 501
 Botanic Gardens, Regent's Park, 51
 Bo tree, ancient, 514
Botryanthus, 194
Bougainvillea glabra, 35
 Bouquets, button-hole, 193, 277; flowers
 for, 90, 139, 251, 329; *Hepaticas* in,
 149
 Bouvardias, culture of, 253
 Box as a scraper, 195
 Boxwood, statistics respecting, 234
 Brake, common, under trees, 498
 Brazil Nuts, 247
 Bridges and embankments, 204
 Broccoli, preservation of, in winter, 268;
 Northampton Hero, 450; planting,
 484; select, 281, 357; successional,
 396; white, 376, 415; various kinds
 of ditto, 393
Brodiaea californica, 396, 416
Brugmansia lutea, 336
 Brussels Sprouts, dwarf, 245; planting,
 467
 Buckley, Mr., death of, 82; fund for,
 102
Buddleia globosa, 498, 499
 Bug, American chinch, 524
 Bulbs, drying off, 190; spring flower-
 ing, 124; spring planted, 395
 Butter cup, fasciated, 396
 Button-hole flowers, 193, 277, 336

C.

Cabbages, sprouting of Early St. John's,
 393; select, 357; best early, 436; cure
 for root grub in, 400; grafting, 190,
 393
 Cacti, edible, 465
 Cactus, winter-flowering, 44
 Cajophora, 173
Caladium tubers, wintering, 364
Caladiums, culture of, 140
Calceolarias, culture and disease of,
 199; bedding, 388
Calcutta cyclone, effects of, 192
Calochortus, *cerulea*, 396; *venustus*,
 520
Caltha leptosepala, 378
Calypso borealis, 378
Camellia, Archduc Etienne, 340; Bianca
 Geraldine, 340; General Cialdini, 217;
 Jardin d'hiver, 217, 238; Matteo Mal-
 fino, 217; *reticulata*, 364; *Valtevareda*,
 198; varieties of ditto, 217
Camellias, bottom-heat for, 318; dis-
 rooting, 232, 238, 254, 272; notes on,
 318; planting out, 151, 168, 198, 217;
 pruning, 314; shaking dead flowers
 off, 336; top-dressing, 276, 295;
 training, 336; white, out of doors, 370,
 395
Campanula gargonica, 498; *tridentata*
 var. *Saxifraga*, 279; *Barrelieri*, 90
Campanulas, alpine, 273

Camphor as a fertiliser, 436; spirits of,
 an insecticide, 456
 Canada, climate of, 394
Cannabis sativus, 215
Cannas on lawns, 436
Cantharidopho, 40
Capsicum, sweet, 232, 245
Carica cundinamarçensis, 500
 Carnations, blooms of, in January, 414;
 culture of, 215, 419; tree, 79; culture
 of ditto, 141
 Carpet beds, plants for, 374
 Carriage drives, 525
 Carrot, Altringham, 360; Belgian White
 Horn, 361; cooking, 399; early
 French forcing, 359; green-topped
 long-red, 361; green-topped white
 Belgian, 362; intermediate Luc, 360;
 intermediate Nantes scarlet, 360; in-
 termediate scarlet, 359; intermediate
 scarlet stump-rooted, 359; James's
 intermediate, 360; long lemon, 360;
 long pied, 360; long Surrey, 361;
 purple, 361; red pale Flanders, 361;
 scarlet horn, 359; short lemon, 360;
 wild, 358; wild improved, 362; white
 Orthe, 362; white transparent, 361;
 white Vorges, 361
 Carrots, cultivation of, 362; early
 forcing of, 111, 362; insects affecting,
 363; preparation of ground for, 231;
 seed of, 362; storing of, 363; various
 kinds of, 358
Carya olivæformis, 274
Cassia corymbosa, 35; genus, 274
Castanea visca, 265
Catalpa bignonioides, 145
Cattleya tricolor, 456; *Bogotensis*, 4
 Cauliflowers, select, 357; planting out,
 167; spring treatment of, 260
Ceanothus integerrimus, 396
Cercis canadensis, 144; *siliquastrum*,
Cedrela, Chinese, 514
 478
 Cedar, red, in Bavaria, 234
Cedum spurium splendens, 236
Celastrus scandens, 144
 Celery, best kinds of, 50; culture of,
 155; early, 289; Major Clarke's, 190;
 planting, 453; preparation of ground
 for, 368; select, 357; sowing, 211;
 Sulham Prize, 146, 155, 314; under
 glass, 135
 Cement for iron, 182; waterproof, 212
Centaurea americana Halli, 81
Centradenia rosea, 190; ditto when cut,
 272
Chamaepeuce diacantha, 52, 245; from
 seed, 373
Chamaerops Fortunei, 500; fruiting of, at
 Boston, 372; ditto at Heckfield, 372
 Charcoal kilns, 778
 Chartometer, a good, 145
 Cherries, 409; black-fly on, 456, 467;
 shedding fruit of, 108; early French,
 438; on walls, 84; ornamental, 202;
 select, 16
 Chestnuts, notes on, 265; the great
 Tortworth, 228; starch from, 92
 Chicory, blanched, 268, 391; treatment
 of, 333
 Chinch bug, 510
Chionanthus, vitality of a bud of, 192;
 virginica, 145
 Chiswick Garden trials, 458
Chloragulum pomeridianum, 81, 102
Clivia miniata, 194
Chrysanthemums, culture of, 484
 Church decoration in New York, 365
Cibotium glaucum, 456
 Cinchona bark, value of, 234
Cinchona or *Chinchona*, 282
Cineraria maritima compacta, 256
Cineraria seed, saving, 418
Cinerarias, culture of, 256; double, 314,
 355, 376; Hayes, 413; dwarf, 500
 Cinnamon, 56, 69
Cissus Davidiana, 199; discolor, to pro-
 pagate, 198
Cistus laurifolius, 499

Citrus japonica, 192
 Cladrastis tinctoria, 144
 Claytonia virginica, 522
 Clematis, alma magna, 456; Blue Perfection, 476; double white, 405; Duke of Edinburgh, 476; Jackmani, 73; J. P. Gassiot, 456; indivisa, 34; Lady Alice Nevill, 475; Lord Nevill, 475; Maid of Kent, 476; Mrs. Hope, 456; ovata, 482; Grand Duchess, 518
 Clematises, culture of, 395
 Clerodendron Balfourii, 33; splendens, 35
 Clivanthus magnificus, 35
 Climate, Canadian, 394; Scotch, change of, 432
 Climbers, indoor, 33
 Cloches for salad growing, 154
 Cloves, 57
 Clubbing in Cabbages, 400
 Cochlostema odoratissima, 175
 Cocoa-nut fibre, uses of, 100
 Cocoa-nut goblets, 26
 Cœlogyne cristata, 59
 Coffee, chicory in, 416
 Colax jugosus, 276
 Colchicum luteum, 192
 Coleus Chameleon, 344; Hero, 396
 Coleworts, sowing, 523
 Colletia horrida, 406
 Colorado Potato Beetle, 101, 128, 272, 296
 Combretum purpureum, 35
 Commons, acreage of, 296
 Conifers, and their synonyms, 286; at Bromesberrow, 434; at Dropmore, 124; at Keir, 252; for a damp situation, 42, 82, 132; new, 233; on chalk land, 56; synonyms of, 228; sowing seeds of, 515; hardness of Hemlock Spruce, 523
 Conservatory Climbers, 34
 Conservatory, open air, 373
 Conservatories, house-top, 282
 Convolvulus, water, 226
 Cookery in various countries, 83
 Co-operation in farming, 47
 Copings, glass, 242
 Coprosma Baueriana variegata, 232, 364
 Cork a covering for tubs, 175
 Cork tree, Algerian, 274
 Corn, Cobbett's, 36; new sweet, Triumph, 393; mummy, 511
 Cornish Moneywort, variegated, 70
 Cornus, a new, 352; florida, 145
 Coronilla glauca in winter, 190
 Cotoneaster at Kilruddery, 124
 Cottage Garden, 369
 Covent Garden Market, improvements in, 59, 192
 Cowslips, American, 219; ditto in North of England, 373
 Cranberry jam, 148
 Cranberry, varieties of, 342; American, 232, 295; culture of ditto, 252
 Crassula lactea, 171
 Cratægus, lobata serotina, 321; pyracantha crenata, 499, 500
 Cratægus, various, 41
 Cricket grounds, draining, 42
 Crickets, mole, destruction of, 524
 Crinum brachynema, 314, 376
 Crocus Byzantinus, 26, Crewei, 478; Imperati, 62, 242, 256; minimus, 214
 Crocuses, varieties of, 136, 194, 280; early, 124; destruction of by birds, 296
 Crops, rotation of, 90
 Croton appendiculatum, 376; Disraeli, 314, 376; tortile, 376
 Crotons, new, 475
 Crystal Palace Show, 474
 Cucumber and Melon culture, 49; and winter plant house, 275; Rollisson's Telegraph, 292, 335, 356; monstrosity, 245
 Cucumbers, bitterness in, 268, 292; early, 32; select, 476
 Cullum, Lady, death of, 168
 Cupressus Lawsoniana, 183; Leeana, 252; macrocarpa, 491
 Currant bushes, aphides on, 490
 Currant Cherry, 433
 Currant, prolific, of Palluan, 433
 Currants, budding, 87; cuttings of, 177
 Cutler testimonial, the, 26
 Cutting-pot maggots, 143
 Cuttings, making, 60; new mode of striking, 257; without joints, 276
 Cyathea insignis, 104
 Cycad, Lamii Roetzlii, 396
 Cyclamen Atkinsii, hardness of, 26
 Cyclamens, at Heatherbank, 136; crossing, 275; for table decoration, 272; large Persian, 168; new mode of growing, 98
 Cycas revoluta indoors, 379
 Cypella gracilis, 44
 Cypress, ancient, 514
 Cyripedium japonicum, 70, 398; selligerum, 456; spectabile, 520
 Cytisus Arduinii, 398

D.

Dacrydium Franklinii, 137; fine specimens of in Wiltshire, 183
 Daddy-long-legs, injury done by, 470
 Daffodils (poetry), 344
 Daffodils, all the, 3, 51, 280; double, 343; in Kensington Gardens, 338; Peruvian, 416
 Dahlias, and slugs, 464; German, 398; summer treatment of, 515
 Daisy-destroying grubs, 314
 Daisy (Quilled), white Globe, 356
 Dalmatian and other insect powders, 25
 Damping fruit houses, 340
 Damsons, varieties of, 446
 Daphne, Cneorum, 464; Gwenka, 352; indica planted out, 44
 Darlingtonia californica, 124, 376
 Darwin a horticulturist, 170
 Dasylirion longifolium glaucum, 456
 Deer, Yew not poisonous to, 370
 Delphiniums, annual, 459
 Dendrobium densiflorum, 385; fimbriatum, 336; heterocarpum, 238; Wardianum var., 456
 Dendrobiums, Indian, 520
 Deodar Avenue, 471
 Deodars at Dropmore, 124
 Deutzia crenata flore pleno, 314
 Deutzias from seed, 228
 Dew, formation of, 248
 Dianthus Highclere, 482
 Dictyogramma japonica variegata, 456, 479
 Digging, drain tools for, 177
 Digitalis, 483
 Dinner-table decoration, 225
 Dionæa muscipula, 26, 507
 Dioscorea retusa, 456
 Dipladenias, 35; culture of, 521
 Dirca palustris, 370
 Dodecatheons, 219, 273
 Dolivot's system of fruit training, 451
 Dracæna candida, 314, 376; elegantissima, 376; hybrida, 356, 376; indivisa, hardness of, 102; ditto in Cornwall, 524; insignis, 314, 376; Smithii, 478; in Devonshire, 292
 Dracænas, 174; for table decoration, 277
 Drain gratings, 155, 181, 220
 Draining gravel walks, 146
 Drains, root-choked, 2, 466; tools for digging, 177
 Drosera not carnivorous, 192; spathulata, 314

E.

Earth heat under turf, 313
 Easter Duddingston, rock-gardenat, 457
 Echeveria fulgens, 153; metallica, propagating, 220; Peacockii, 458; secunda glauca, wintering, 102
 Echinocactus Simpsoni, 378
 Edelweiss, the, near London, 464
 Edging plants, 373; Primula cortusoides as, 256; Selaginella as, 336
 Edgings, garden, 69; kitchen garden, 102
 Elæagnus japonica variegata, 272
 Ellwanger & Barry's nursery, 238
 Elms, burrs on, 491
 Elysée, garden of the, 486
 Embankments and bridges, 204
 Embotrium coccineum at Belgrave, 338
 Emigrants, Nebraska, 58
 Enclosure Commission report, 272
 Endive, culture of, 155; in London market gardens, 101; select, 357; running to seed, 533
 Engine-room, greenhouse, 501
 Epiphyllum truncatum, 44
 Epping Forest enclosure, 282
 Eriogonum, compositum, 81; racemosum, 81
 Erythraea Muhlenbergii, 280
 Erythronium, americanum, 356, 357; dens canis, 194, 319, 356, 357; Nuttallianum, 357; giganteum, 357, 376; grandiflorum, 357
 Eucalypti, from seed, 434; heights of, 84; in Algeria, 84, 458; large, 183; various, 247; cornutum, 26; globulus in California, 352; in the Riviera, 202; not hardy, 336; hardiest, 471
 Eucharises, 194
 Eucomis punctata, 256
 Eonymuses, various, 119
 Euphorbia, amygdaloides, 498; Jacquiniæflora, 35
 Eupatorium ageratoides, 272
 Eurya japonica variegata, 115
 Euryangium Jumbul, 2

 Pear tree, the, 409
 Pear trees, distances apart, 131; furnishing walls with, 19; re-grafting old, 225; destruction of grubs on, 526
 Pea, edible-rooted, 416; sugar, 415; Sweet, 254
 Peas, American, 296; best late varieties of, 392; Culverwell's Marrow, 82; in pots, 498; early, 533; forcing ditto, 470; everlasting, 524; keeping mice off, 416, 456; mulching, 498; remedy against mildew in, 498; select, 357, 476; sowing, 157; ditto, late, 428; treatment of early, 280; trench culture of, 289; William the First, 456
 Peccan nuts, 274
 Pelargonium Beauty of Oxtou, 456; Constance, 128; Countess of Dudley, 456; Eclipse, 456; Edith, 456; Flirt, 456; Miss Porter, 456; new type of, 22; Prince of Wales, 475; Queen Victoria, 466; Revenge, 456; Sappho, 456; trial of, at Chiswick, 296
 Pelargoniums, inarching, 416; culture and propagation of, 479; culture of specimens of, 412; zonal, for winter-flowering, 485
 Pentstemon antirrhinoides, 274; cyananthus Brandegei, 81; Palmeri, 81
 Peonies, list of, 110; tree, 418
 Persimmon, Japanese, 222

- Petræa volubilis*, 378
Petunia intermedia, 452
Phajus grandifolius a cool conservatory plant, 318
Phalenopsis intermedia, 192; *Veitchii*, 234
Phegopteris Dianæ, 456
Philadelphia exhibition, 386, 478
Phlox verna, 416
Phormium tenax in Ireland, 205; various kinds of, 320
Phyllocactus bififormis, 274
Phylloxera, history of the, 157; remedy for, 128, 234, 412, 498
Picea, *amabilis*, 287; *grandis*, 286; *magnifica*, 287; *Parsoniana*, 287
Pine-apples, culture of, 337; *Queen*, 105; shading, 324, 356, 383, 432; *St. Michael*, 30; *West Indian*, 316; potting, 86
Pine insects, 327
Pines, dwarf, 25; large *Scotch*, 119; red-rot in, 322
Pinetum, *Gordon's*, 233
Pinguicula grandiflora, 398, 415, 483; *Vallisneriaefolia*, 436
Pink, *Catchfly*, *Bolander's*, 396; forcing, *Derby-day*, 456
Pipes, hot-water, 22
Pitcher plants at *Drumlanrig*, 233, 258, 295
Pittosporum crassifolium, 452
Pinus Mugho, 25; *Pinea*, 350
Plane, new variegated, 228
Plant-growth, silica not essential to, 96
Plant house, Cucumbers in a, 275
Planting, in groups, 472; out *v.* pot culture, 519
Plant perfumes, effect of, on health, 393
Plant protectors, construction of, 108
Plant, Soap, 102
Plant stand, 379
Plant sticks, 478
Plants, absorption of water by leaves of, 26; *Alpine*, at *Easter Duddingston*, 457; ditto, localities for, 236; *April-flowering*, 449; arrangement of border, 136, 165; bedding, best varieties of, 172; ditto in *Parc Moncean*, 89; *carnivorous*, 117, 390; certified, 40; changing natural forms of, 150; comparison of flowering seasons of, 296; *Darwin's insectivorous* and climbing, 62; dates of flowering of, 296, 346; dinner-table, 225; early treatment of, 401; early-blooming, 104, 296, 462; ditto herbaceous, 376; effects of the winter on, 443; for carpet-beds, 374; for edging, 69; for town baskets, 316; for trellises, 290; for vases, 461; hard-wooded, top-dressing, 257; hardy autumn flowering, 190; ditto, blue flowered, 238; ditto, climbing, 236; ditto in Gloucestershire, 395; ditto, under glass, 115, 175, 198; sowing seeds of herbaceous, 222; indoor climbing, 33; in *Evelyn's* time, 397; in flower at *York*, 437; in schools, 228; *Japanese* mode of packing, 504; new *Japanese*, 352; May-blooming, 502; movement of sap in, 31; new, 475; ditto, *Australasian*, 500; not *carnivorous*, 192; ornamental, 205; propagation of bedding, 71; rock-garden, 377, 477; ditto, white-flowered, 220; room, diseases in, 21; ditto, insects injurious to, 261; sea-side, tree *Lupines* as, 220; spring moving, 389; sub-tropical, indoors, 149; ditto, in winter, 116; sweet-scented, 72; variegated, 373; watering, with hot water, 507; wax-yielding, 95; woodland, in *Vermont*, 72
Platycerium, alciorne, 456; *Wallichii*, 456
Pleasure grounds, maintenance of, 437
Plumbago capensis, 34; *rosea* in winter, 153
Plum, *Chickasaw*, 520; *Jamaica*, 170; *Wild Goose*, 486
Plum Tree, the, 410
Plums, ornamental, 202; select, 18
Poinsettia pulcherrima, 43; in *New York*, 465
Poisoning, *Yew*, 259, 311
Poison, mineral, use of, 350
Pollen? Is fruit changed by foreign, 24
Polyanthuses, gold-laced, 317; origin of, 484
Polystichum lepidocaulon, 475
Pomegranates without pips, 396
Pomellos in *Covent Garden*, 148
Popocatpetl, 26
Poplars, various, 288
Poppies, giant scarlet, 484
Posies for the poor, 530
Potato beetle, *Colorado*, 101, 470
Potato boiling, *Buckmaster* on, 211
Potato, *Brownell's Beauty*, 391; *Eureka*, 391; *Carpenter's Seedling*, 391; *Carter's American Bread Fruit*, 396; *Compton's Surprise*, 190, 391; *Early Rose* in *France*, 211; *Excelsior*, 391; *Extra Early Vermont*, 391; *Ice Cream*, 391; *Red-skinned Flour-ball*, 102; *Snowflake*, 39, 470; the *Sextus*, 291; *American*, 391, 491, 507; *Early forcing* of, 111; ditto, how to obtain, 188; ditto raising of *Lancashire*, 108; from cuttings, 244; new at *Christmas*, 338; new race of, 243; picking blossoms off, 567; Seedling, how to raise, 245; superphosphate for, 122; two crops a year of, 244; select, 357; storing, 245; *Potato beetle*, *Colorado*, 520
Potato crop at *Newark*, 268
Potato culture, 14; at *Killerton*, 507; for exhibition, 37, 50, 146
Potato disease, new, 37, 500, 532; remedy for, 470
Potato planter, 245; *Whitford's* ditto, 58
Potato Planting, best time for, 217, 338, 376; in autumn, 207
Potato sets, 134; economical mode of cutting, 244
Potato show, *International*, 356
Potato trials, at *Chiswick*, 76; at *Reading*, 210
Potatoes, *Channel Island*, 533
Pot trellises, 143
Pots, clean *v.* dirty, 413; glazed, the best, 480; and worms, 198; planting out better than culture in, 519
Preserved fruits and vegetables, 213
Primroses, *Chinese*, 152, 216, 217; early pink, 336; *Scotch Bird's-eye*, 396; sowing, 124, 364, 414; variegated, 319, 345; double, propagating, 198; double yellow from seed, 200; for table decoration, 277; for the greenhouse, 272; mountain, 337; on railway embankments, 450
Primula, altaica, 90, 111; *cortusoides amcena*, varieties of, 383; *cortusoides* as an edging plant, 256; *farinosa*, 483; *japonica*, hardness of, 373, 464; in *North Wales*, 484; *pulcherrima*, 503; *scotica*, 395; *sinensis Stewartii*, 198; various, 345, 377, 378
Prince's Feather, 504
Privet, *Lilac* grafted on, 437
Protections, fruit tree, 213, 217, 230, 294, 295; how to make screens for, 108; glass, 38; hay as, 292; straw mats for, 242, 490; various materials as, 246
Pruning, close, exhausting effects of, 267
Prunus americana, 144; *caroliniana*, 144; *cerasus*, 144; *maritima*, 144; *serotina*, 144
Psidium, 168; *Cattleyanum*, 252
Puschkinia scilloides, 195
Pyracantha crenata, 489; *japonica*, 500
Pyrethrum, *Golden-feathered*, wintering, 320
Pyrus americana, 145; *coronaria*, 145, 278; (*malus*) *floribunda*, 406; *pruniflora*, 274
- Q.
Queensland, botanical productions of, 234
Quercus glabra, fruiting of, 292, 314
- R.
Rabbits and tree-barking, 195
Radiation, terrestrial, 181
Radish, new *Japanese*, 436
Radishes, culture of, 155; early, 134
Railway embankments, flowers for, 463; Strawberries on, 446
Rainfall and sunspots, 60

MR. NINIAN NIVEN.

As the last volume of THE GARDEN was prefaced by the portrait of the most distinguished landscape gardener in England, so the present is accompanied by that of MR. NIVEN, who has long been known as the leading practitioner in the same art in Ireland.

MR. NIVEN was born in the year 1799. He was the son of a gardener who, in his generation, was well known by those belonging to the old school of Scotch horticulturists, of whom, though many came south of the Tweed in keeping with a weakness inherent in Scotchmen—some still remained behind, and not a few of the present race of gardeners will, as they look back through the vista of years, still retain pleasing recollections of their early days spent under MR. NIVEN, at Keir House. His birth place was Kelvin Grove, in the neighbourhood of Glasgow; or, to be more particular, at what now forms the noble West Park of Glasgow: there he spent his early years, and there he received his education. At the age of fourteen he appears to have developed a taste for the profession of his ancestors, and felt it incumbent upon him to follow in their footsteps.

At the gardens of Bothwell Castle, then, amongst the best in the West of Scotland, and famous for an unusually valuable collection of plants—a fame, by the way, that, after a lapse of sixty years, yet attaches to the place—MR. NIVEN was bound apprentice, at the age of fourteen, under MR. THOMAS BUTLER, the then gardener, and predecessor of the present MR. TURNBULL, whose name will always be remembered as the greatest Heath grower of the day. Here no opportunity was lost in studying the numerous botanical rarities with which he was daily brought in contact; here was laid the foundation of his botanical knowledge; and, possibly, here his young mind became imbued with that love of the picturesque and beautiful in Nature for which he has become so distinguished, and which few places were more likely to give rise to than the romantic banks of the Clyde, from Bothwell Castle to its furthest source. Having completed his apprenticeship, he returned to Glasgow, in order to study drawing and painting, in both of which arts he had made considerable self-taught progress, utilising in this manner his long winter evenings of Scotch bothie life. Further, his knowledge of plants and his love for the science of botany, gained for him the friendship of the late MR. STEWART MURRAY, of the Glasgow Botanic Garden, and also of the late SIR W. HOOKER, and, under the able tuition of both of these gentlemen, he made rapid progress. A recall to Bothwell Castle, to take charge of the flower garden, interfered with the course then selected, and for which his studies were preparatory, namely, a botanical collector's life. Doubtless, with the sad fate of his old friend and associate, poor DOUGLAS, in his mind, he has long since reconciled himself to the change that then took place in his destinies.

In the year 1822 he went as gardener to Belladrum House, in Inverness-shire, where he had, as a neighbour, the late MR. DONALD BEATON, who, in a reminiscence of his early Scottish life, published years ago in the "Cottage Gardener," bore ample testimony to the energy and ability displayed by the young Glasgow gardener who had come to the far north. Those were days when a journey to the North of Scotland was almost as protracted as a journey at the present time is to America. He had scarcely been two years in his first situation as gardener before he was requested, by the then EARL OF GLENELG—who, if we mistake not, was then Chief Secretary for Ireland—to take charge of the gardens at his official residence in the Phoenix Park, Dublin. These, with ample scope and means, he remodelled. Introducing a new and methodic

system in all departments, he soon made them worthy of the brief but expressive criticism of the late Mr. LOUDON, when making a professional tour in Ireland, as recorded in his "Gardening Encyclopædia," that "it was the best managed garden in Ireland." MR. NIVEN's residence here extends over some nine or ten years, during which period he carried off a vast number of prizes at the horticultural shows. About this time the Curatorship of the Royal Dublin Society's Gardens became vacant, and he was then asked to compete for this, the premier post of his profession in Ireland, and was successful in the competition. For five years he discharged the duties that here devolved upon him so entirely to the satisfaction of the Council, that when, in 1839, he resigned his post, he received, at the hands of the Royal Dublin Society, a very handsome presentation. During the above period the grounds had been thoroughly remodelled, and great and important improvements made—improvements which have been since further modernised, and, which under the skilful management of his successor, the present DR. MOORE, render the Glasnevin Gardens a credit alike to the profession and to the country.

During the latter part of MR. NIVEN's curatorship his time was occupied to a considerable extent in carrying on professional work, and, after resigning his post, he devoted his energies entirely to the career of a landscape gardener, and has since been employed in that capacity in all parts of the country; and it would be easy to point out numerous instances where his art has assisted Nature in a manner only possible to one who was a born landscape gardener. During the thirty-four years of his life devoted to this delightful employment, he has further organised horticultural and experimental nursery grounds at the Garden Farm, Drumcondra, not far from Dublin, where, besides an admirably managed nursery, containing the finest collection of fruit trees in Ireland, are to be found a choice assortment of botanical specimens, and alpine and herbaceous borders containing mementos of the olden time, when the countless scarlet and zonal Geraniums, the Verbenas, Lobelias, and other florid elements of the modern system of flower gardening, had not as yet seen the light.

Amid the many claims on his time in connection with his professional career, as well as the entire management of his home nurseries and experimental garden, he was a not unfrequent contributor, on botanical subjects, to the periodical literature of the day, more especially in early life, and we find his name constantly occurring in "Loudon's Magazine." A valuable essay on the cultivation of the Potato, written many years ago, carried off the gold medal offered by the Royal Dublin Society; this was succeeded by a second pamphlet on the Potato disease, and, just before the close of MR. NIVEN's residence at Glasnevin, he published a popular guide to those gardens, the first, we believe, that had been attempted of any botanical garden. With the "Guide" proper was incorporated a text-book on practical botany, the object being to popularise a science that, at the period we speak of, had but few votaries among the general public. To these may be added one of the best practical treatises on the cultivation of Asparagus, the value of which is fully appreciated even at the present day.

Those who have had, as we have, the pleasure of a long acquaintance with MR. NIVEN, will bear witness to his professional and intellectual attainments, and to the courtesy with which he invariably met all who paid him a visit at his Garden Farm at Drumcondra. At the present time, at the age of seventy-five, his faculties retain their youthful vigour not only unimpaired, but matured by the experience of a professional career far longer than that allowed to most men. We trust that this experience may extend over a still longer period, and that he may continue to enjoy for some years yet the position to which his energy and ability have raised him; a wish in which we are sure his numerous friends, both in and out of his profession, will heartily unite.

THE GARDEN.

VOL. VII.

TRANSPLANTING HOLLIES.

By JAMES M'NAB, Royal Botanic Gardens, Edinburgh.

As I have often been consulted in regard to planting and transplanting Holly hedges, I will give the result of my experience on these subjects as briefly as possible. There is, perhaps, no species of hardy evergreen now in cultivation better adapted for forming hedges than the common green Holly. It is beautiful at all seasons, bears cutting-in without injury, and makes a most impenetrable and a very ornamental fence. A feeling, however, prevails against its general use in consequence of its having the reputation of being a plant of comparatively slow growth. If properly attended to, however, after planting, it will soon make a good and serviceable hedge. Some Holly hedges are now known to be in good condition, although planted upwards of a century ago; and, notwithstanding that the points of the shoots are regularly clipped off, they manage to cover in time a large space of ground. This cannot be avoided, as the lateral branches continue annually to elongate, unless temporarily disfigured by close cutting-in, say once every twenty or twenty-five years. Holly and Yew make the best evergreen fences which we have in this country; and, like the Holly, the Yew bears cutting-in well; it is, however, more subject to blemishes from various causes than the Holly, and it is less easily put right when injured. When a young Holly hedge is to be formed the plants used for it should not be less than from 18 inches to 2 feet in height. It is necessary, too, that they should have been frequently transplanted previously to being used, and that, during such removals, the roots should have been occasionally cut-in, so as to induce the formation of fibres from the cut surfaces. If the ground selected for planting the hedge should be near the nursery in which the plants grew, or at such a distance from it that the young plants can be taken in a cart with as much soil as possible attached to their roots, all will go well; but, if they have to be transferred to a distance, it is absolutely necessary to have them on the property for a year or so before being used. When received direct from a nursery establishment they are apt to be more bared of soil at their roots for the purpose of close packing than is desirable for immediate hedge-making purposes; and, therefore, the importance of having them in nursery rows in the ground for some time before being made

into a hedge, and when wanted for that purpose they can be lifted with sufficient adherent balls of earth for permanent planting. By this mode of treatment it will be found that fewer plants will answer the purpose, and that the future success of the hedge will be more complete than it otherwise would be. After the ground for the reception of the young hedge has been properly trenched and prepared for the purpose, plants should be put in with well manured soil, and afterwards watered freely with diluted liquid manure, and this should be repeated several times throughout the season. This liquid manure will be found an excellent stimulant for all young Hollies, whether planted singly or in hedge lines. After being one year planted the hedge should be slightly clipped in on each side, and this practice should be continued annually for many years afterwards, so as to induce an upward growth which it will rapidly take if the ground is in good condition. This side clipping should be accomplished during the month of September, or as soon as the young shoots are found to be properly ripened. When the hedge attains the height of 5 or 6 feet it should be regularly topped, leaving, however, one strong plant at, say every 20 feet, to form a leader, and these must be reduced to 40 feet apart, as the hedge gains strength and vigour. These leaders should be knife-pruned till they become 3 or 4 feet in height. When they are strong and somewhat aged, it will be found that they will fruit abundantly, which the hedge never can be expected to do so long as clipping is resorted to. As to transplanting large Holly hedges, say from eighteen to twenty years old, such hedges may be removed with perfect safety, provided the ground is opened up on each side a full year previous to removal, and all the large roots which come in the way are cut and smoothed over, particularly at the edges, with a sharp knife, instead of being hacked off with a spade, as too frequently happens, when few or no rootlets will be formed from their rugged extremities, whereas the smooth knife-cut roots will be found to put forth numerous fine roots. The trench may afterwards be filled in with leaf mould and sand mixed with the ordinary soil thrown out, applying a good dose of water after it has been filled in, and then allowing it to stand for a year. Autumn will be found to be the best time for root-pruning, and the hedge may be removed to the place selected for it during the following autumn or the spring of the twelvemonth. When removal takes place, the hedge should

be lifted in flakes, large or small, according to the distance to which it is to be conveyed and the appliances at command. If the distance is short, it can be laid over in pieces 3 or 4 feet long on a large board or four-handed barrow, and carried to the new trench, into which they can be slid in an upright position. After planting, fill in with good soil, and water freely, cutting off any protruding pieces that cannot be easily worked into the neighbouring flakes. If a dry summer should follow the transplanting, an occasional syringing will be desirable. With older hedges, say from thirty to forty years' standing, it is necessary to cut in the branches on each side to within 8 or 9 inches of the main stem, and to head down to within 5 feet of the ground, smoothing and darkening all the incisions. A trench should then be made on each side; all large roots should be cut off and prepared, as recommended for hedges of smaller size, and afterwards the trench should be filled in with good soil. After standing for a year or so, the hedge may be removed with impunity, either in single pieces or short flakes, shortening in the intertwining branches during the operation of lifting. With good feeding and watering, such a hedge will soon break out all over, and will again make a beautiful green fence. It will be necessary, however, to have a number of young plants at hand, in order to fill up any wide gaps that may be occasioned whilst transplanting it to its new situation. It often happens that portions of very old hedges get out of shape from various causes, and are often seen covering a large space of ground. In such cases I would recommend that all the stems should be shortened to the height wanted, say 6, 7, or 8 feet, and that all the branches should be well cut in on both sides. After this, lay a good coating of old manure and soil over the surface of the ground. Trench about $2\frac{1}{2}$ feet deep along each side, and about two feet from the old stems, forking the material well in among the roots on each side while filling in, as well as over the surface of the ground left close to the stem, and afterwards covering the ground with good soil, so as to keep the finished surface on each side about 4 or 5 inches above the ordinary ground level. By this treatment, fresh vigour will be infused into the old cut stems, much ground will be reclaimed, and the hedge will soon be made to assume its proper shape again. In the case of very old hedges, this operation had better be done late in autumn, and the stems will be found to break out freely during the following spring. The Holly, although undoubtedly a hardy plant, has occasionally been injured by frost, as happened in many places during the winter of 1860-61. At that time a hedge under my care had to be cut down to the level of the snow, which then varied from 18 inches to 2 feet in depth. As the low side branches were unkilld (being then under snow), they were all cut close in on both sides with a hedge-bill, and good soil was afterwards trenched in on each side to within 10 inches of the root portion of the stem. This hedge is now 6 feet in height, and has been so for a long time, and is as neat in appearance as it was before the injury took place. Another hedge of the same age, and injured at the same time, had only the dead tops removed; afterwards it received no attention, owing to its being in an unprotected situation, and now it is in a very dilapidated condition. Although the autumn months are generally considered to be the most favourable for transplanting Holly hedges, that operation may also be carried on in spring with perfect safety. If the summer, indeed, should be at all moist, little difficulty will be found in transplanting a Holly hedge during any month in the year, provided it has been previously prepared, and the newly-made shoots in stout short lengths. If the weather should prove dry after planting, a coating of new-mown Grass, placed on the surface of the ground on each side, will greatly benefit it, by keeping the surface moist; and, besides this, an occasional syringing night and morning may also be given with advantage. Although Holly hedges are often seen in gardens and pleasure-grounds all over the country, they are but rarely seen as a fence for agricultural purposes. If thus employed, in many places they would succeed admirably, and prove both efficient and durable, besides being pleasing to the eye. For railway fences, Holly hedges would have a good effect; and, if they received the same amount of attention, they would prove quite as ornamental and useful as the Thorn for such purposes.

NOTES OF THE WEEK.

— THE exhaustive article on Daffodils, by Mr. Niven, which we publish this week, we have preferred inserting, though lengthy, in one number, notwithstanding that we are, in consequence, prevented from publishing our usual variety of matter. The importance of the beautiful Daffodil family in the embellishment of gardens of all kinds makes us feel, however, that a complete and illustrated history of the family will be appreciated by all lovers of hardy flowers. The article will be found useful for reference for many years to come. With the exception of three of the cuts purchased from Messrs. Vilmorin, of Paris, all the illustrations have been drawn by Mr. Burbidge and engraved by Mr. Hyde.

— MR. WM. PAUL's exhibition of Roses in pots, pictorial trees, Geraniums, and other plants, furnished from his nurseries at Waltham Cross, will this year be held at the Royal Botanic Society's Gardens, Regent's Park, from the 3rd to the 10th of May inclusive.

— THE Alexandra Palace Company announce that the new palace and park will be opened on the 1st of May next.

— THE Barnes Fund, we learn, must soon be closed. The sum collected is still under £200, and, as it is desirable that that amount should be obtained, we trust that such as have not yet subscribed will lose no time in giving their support to so good a cause.

— MESSRS. BACKHOUSE write to us from York to say that Fahrenheit's thermometer registered 31° of frost there on the morning of the 30th ult., in low open ground, being 1° only above zero. They state that they also hear of a similar reading on the other side of that city.

— A NEW book on Ferns, called "The Fern Paradise," by Mr. Francis George Heath, is to be published by Hodder and Stoughton. It purports to be a plea for the culture of Ferns, and will include descriptions of ferny rambles through the green lanes, the woods, and the glens of Devonshire.

— THE council of the Royal Horticultural Society have undertaken to hold five evening meetings in 1875, at which papers will be read and discussion invited on details of the science and practice of horticulture. These meetings are fixed for the following Wednesdays, at eight o'clock, p.m., viz., January 13th and 27th, February 3rd and 24th, and March 10th.

— AT a recent meeting of the Edinburgh Botanical Society, Mr. Potts of Fettesmount, exhibited a mass of roots of the common Poplar, taken from a drain pipe, which they had completely choked up for a space of 40 feet, a growth of less than five years. Mr. Greig of Glencase, instanced a case of roots of a Willow choking up a 4-inch water pipe for a considerable distance within four years after the pipe had been laid.

— THERE is at present in bloom in Mr. Bockett's fine collection of Orchids (recently moved to Stamford Hill), a splendid plant of the beautiful and very rare *Lælia anceps Dawsonii*. It has on it three spikes, bearing seven lovely and delicate blossoms. It is in fine health, and is one of the most charming of all late-flowering Orchids. There is also in the same collection a wonderfully fine form of the *Lælia albida*, much superior, both in size and marking, to the ordinary kind. It is a very large specimen (on a block), some 2 feet by $2\frac{1}{2}$ feet, in vigorous health, and is bearing thirty-five flowers.

— MR. WOBST, of the Moscow Botanic Garden, has this year succeeded for the first time in raising the Sumbul plant (*Euryangium Sumbul*) from seed. He sowed the seeds in the autumn of 1873 in a dung bed, and covered them up later with snow and lights; they germinated freely in the spring. One notable characteristic is the manner of the development of the first leaves, which appear below the Cotyledons, a peculiarity not unfrequent in *Anagallis arvensis*, several species of *Euphorbia*, *Antirrhinum*, &c., and previously observed in some species of *Umbelliferae*. Mr. Wobst has found that the Sumbul invariably dies after once flowering; of all the plants that have flowered with him not one has thrown up a second flower. Two varieties of Sumbul root appear to be imported into this country for use in medicine, one known as Russian, and the other as Indian Sumbul. The former occurs in circular pieces ranging from $2\frac{1}{2}$ to 5 inches in diameter, and from $\frac{1}{2}$ to $1\frac{1}{2}$ inches thick; they are simply sections of the root cut across and dried, and have a dirty-brown appearance, and a roughish dark brown bark often covered with short bristly fibres. The substance of the root is coarsely fibrous and spongy, and it has a very powerful odour of musk, and a bitterish acrid taste. That known as Indian Sumbul is said to be imported from Bombay, and sometimes round by China, whence it has been called China Sumbul. It is somewhat closer, firmer, and of a more reddish tint than the Russian, and the odour is scarcely so powerful. It is used as a stimulant and anti-spasmodic in nervous affections, typhoid fevers, &c., and is usually given in the form of a tincture, but also as a powder.

THE GARDEN FLORA.

ALL THE DAFFODILS.

By J. C. NIVEN, Botanic Gardens, Hull.

Historical Remarks.

If there be one genus of plants that belongs to the region of poets and poetry more than another, it is the *Narcissus*. Theocritus, Ovid, and Virgil have sung in classic strains the poetic circumstances of its birth—how the enamoured youth, whose patronymic the genus perpetuates, sacrificed his mortal existence (if, by the way, mortal he may be called) on the altar of his own vanity, and attained a full meed of immortality as representative of the whole family of our charming Daffodils. The old Sicilian botanist, Dioscorides, before the Christian era had dawned, mentions several distinct forms, and records certain medicinal virtues which they possessed, some of which were doubtless due to a lively imagination. Our old herbalists, such as Parkinson, Dodonæus, and others, give rough, but very expressive, figures of the various species then known, which, associated with their quaint descriptions, are exceedingly interesting, and sometimes highly amusing. Linnæus describes nearly a dozen species, most of which still retain the names under which they were described by him—one of the many silent testimonies that our modern botanists bear to the clear discernment and sound judgment of that master-mind in our special field of science. Some fifty years ago, or less, there appears, however, to have been a sort of *Narcissal* cyclone in the floral world within our island, and, suddenly, we find the species increased by scores; for as many as 150 were enumerated and described by Haworth, in his "Monograph," published in 1831. In fact, so overwhelmed was he by the magnitude that the old genus had attained under his indefatigable—though not always judiciously discriminating—observation, that, in the same "Monograph," he immolates *Narcissus* once more, and raises from the ashes some sixteen genera, for several of which such as *Diomedes*, *Ganymedes*, *Ajax*, and *Hermione*, he harks back to the mythological regions, by way, I presume, of poetic compensation. To anyone familiar with the genus, it will be evident that Haworth considered the slightest variation in size, shape, or colour of any of the parts, sufficient to form the basis of a new species. No doubt there was much of uncertainty in his time as to what constituted a species; nor, indeed, has the lapse of half a century, with all its scientific progress, tended much to remove that doubt, and the question as to what a species is still remains unanswered, whether it be put with reference to this or any other genus. Dean Herbert, who devoted a long career to the study of the natural family to which the *Narcissi* belong, and who, from being an indefatigable hybridiser, ought to have been fully impressed with the inconstancy of characters thus acquired as available for descriptive botany, and the extreme danger of attempting to give them a specific value, modified Haworth's enumeration, in so far that he reduced the genera to six, and relegated many of the species to varieties; he might have gone further and called them very doubtful variations. Some allowance must be made in both the foregoing cases. Each cultivator was an enthusiast—each had accumulated a large collection of Daffodils—each, doubtless, was the possessor of one of those old-fashioned gardens where Nature reigned supreme, and where Art was banished to the outer world. In both, the fertilising pollen of the Daffodil was borne from blossom to blossom by insects, and thus crosses and intercrosses formed that, in course of time, led to many variations—some merely temporary, some permanent—but all were elevated to a position far above their rank or station. Then, again, when the mind of an enthusiast is bent on discovering a distinction, how prone it is to magnify differences that the eye of one less sanguine would detect as a mere variation, arising from such causes, as soil, situation, or season. Possibly the enthusiast may retaliate, by saying the eye of the outsider is uneducated, and consequently unable to appreciate such fine distinctions. Knowing how futile it is to attempt to define the word, a species ought to have at least sufficiently constant and distinctive characteristics as may be embodied in an intelligible description; and, moreover, all species ought to

emanate from some locality where they are indigenous, and not from the precincts of a garden wherein the original types have been accumulated, and, in the course of years, have become involved in an almost inextricable confusion of inter-breeding. Our Continental brethren appear to have been perfectly satisfied with the labours of Haworth and Herbert, which they deemed as exhaustive, and hence we find Kunth, in his valuable work on *Monocotyledons*, embodies their ideas almost in their entirety. The next phase that presents itself in the history of the genus is the culminating one. In the spring of 1869, a prize for a certain number of species of *Narcissi* was offered by the Royal Horticultural Society, evidently betokening that, after a long period of neglect, they were again becoming claimants for popular favour. But here arose a difficulty, and a very serious one, as the prize was offered for a number of species—what would be considered by the judges a species, and what a variety? From my foregoing remarks, it will be evident that the judges would be placed on the horns of a dilemma. Fortunately, Mr. Baker, of the Kew Herbarium, than whom no one could be better fitted to solve the difficulty, volunteered his services, and prepared a most elaborate analysis of all the known species, which was duly published that year, and in which the whole category of genera, in spite of their immortal names and mythological associations, were swept away, and *Narcissus* himself re-established, as of old, on his ancient throne. Out of 150 so-called species, only twenty-one were found to bear the stamp and impress of true specific character, those others that possessed permanent distinctions being placed as varieties under the head of their specific types. With this wholesale but judicious reduction I entirely agree—so entirely that I intend availing myself of Mr. Baker's excellent analysis as the basis of the following series of short paragraphs by which I purpose describing the accompanying admirable illustrations, and which I hope will complete an historical, descriptive, and cultural monograph, such as, I trust, may prove of value alike to the amateur and the general cultivator. Before closing these remarks, I ought to say that as some forty years had elapsed between the Golden Age of Haworth and the Iron Age of Baker, nearly all the old collections had died out; hence this vigorous onslaught cannot have been so keenly felt as otherwise would have been the case. Some twenty-eight years ago I found at Kew a collection of about 110 named species, the greater part having originated from Haworth's stock. These I gradually reduced during the five years they were under my charge to fifty-two in number, and many of these I find, on looking over one of my old note-books, are referred to as only varieties. From this it will be readily seen that I was quite prepared to endorse even Mr. Baker's sweeping reduction.

Natural Affinities, Geographical Distribution, &c.

The genus *Narcissus* constitutes the type under which a group of six natural orders, with a tolerably close affinity to one another, are arranged by Lindley in his "Vegetable Kingdom," under the title of the *Narcissal Alliance*. They are botanically characterised by having the ovary inferior, the flowers symmetrical, and the seeds albuminous. The largest of these Orders, and that to which our plant belongs, is *Amaryllidaceæ*, the *Amaryllis* family, an Order consisting for the greater part of plants with extremely showy flowers. This will be at once admitted when I say that, besides our *Narcissi*, we find in its ranks such plants as the *Galanthus* or *Snowdrop*; the *Amaryllis*, in all its lovely and brilliant shades of colour; the *Vallota*, or *Scarborough Lily*; the *Nerine*, or *Guernsey Lily*; the rarer *Griffinia*, with its charming blue flowers; the *Pancratium*, with its delicate purity and delicious fragrance; and the *Crinum*, a very giant among bulbous plants. These and many others that constitute the first two sub-divisions of the Order have all bulbous underground stems. In the third tribe we have the *Alstroemeria* and the *Bomarea*, alike lovely and remarkable for their great variety of colour, producing in place of bulbs fleshy underground tubers; and in the fourth tribe we have the giant *Agaves*—erroneously called *American Aloes*—in which the bulbous character disappears, and is replaced by thick, fleshy, spinous leaves, fleshy roots, and a perfectly arborescent development of flower stem. To the superficial observer the connection of this tribe with

our humble growing *Narcissi* will be somewhat puzzling; but in floral structure there is a sufficiently close analogy to warrant the relationship. The special peculiarity of the *Narcissus* tribe consists in the presence of a distinct cup-like appendage between the petals and the stamens, called by old authors the "nectary," but now more generally known as the "corona," or crown. It is analogous to the ring of filamentous appendages that we are familiar with in the Passion Flower. The origin of this coronal growth is by botanists attributed to a disposition on the part of these plants to develop an increased number of stamens. In the *Pancratium*, an allied genus, the filaments of the stamens are confluent with this appendage, and in some species between each stamen arises a small bilobed process that has evidently a close relationship to a modified anther. Be the origin, however, what it may, we find that this peculiar growth gives us a character of sufficient constancy as to be available for the grouping of the species into three distinct divisions. The geographical distribution of any genus is, to my mind, always a subject of especial interest—how cosmopolitan some plants are found to be; how local others; nor are we always able to assign reasons for these differences. Our *Narcissi* are—so far at least as our present knowledge goes—almost wholly confined to Southern Europe; three or four species extend southward to the Mediterranean shores of Northern Africa; one at least is indigenous to Britain, and found as far north as Sweden, and one appears to extend eastward—through Syria and North India—to China and even Japan. On the other hand, we have not a single species indigenous to either North or South America. True, in the "*Flora Peruviana*" we have one species described under the generic title of *Narcissus*, but it evidently belongs to a distinct genus, *Ismene*, and must be looked upon not as an immediate member of the family, but as a distant relation in a distant land. I admit that I have had bulbs of *Narcissi* sent home from Lima—genuine *Narcissi*—but these have, no doubt, been taken there originally by the Spanish monks; and to a similar source, I am disposed to believe, do two of the three species, which are said by some authors to be natives of Britain, owe their introduction. If the sites of some of the old massive monastic buildings themselves have disappeared, it will surely be a matter of surprise to none that the limits of their old gardens have vanished, and still less that, in the course of centuries, the plants thus introduced will have escaped far beyond those limits, and established themselves in adjacent districts. We have many other instances in which our *Flora* has been originally indebted to this source for some of its so-called endemic plants. Australia has no representative of the genus—nor, so far as my knowledge goes, does it favour us with its analogue. The same remark applies to the Cape of Good Hope. We may, therefore, conclude that the home of our *Daffodils* is Southern Europe, from which they have digressed northward through Britain to Sweden, and eastward, by a very delicate streak through India, as far as Japan. Respecting the medicinal properties of the *Narcissi*, I have already stated that our old herbalists have recorded in their favour, besides many "virtues," as they were wont to term them, not a few vices; and the generally accepted idea is, that the bulbs are somewhat poisonous and emetic. This is confirmed by Lindley and other modern writers; and, further, that the flowers, especially those of the large *Daffodil* of our woods and gardens, are also poisonous, and, when eaten, as they have been by children, have been attended by serious results.

Explanatory Remarks upon Technical Terms.

However popular the writer's aim may be in giving a botanical description of a plant, it is utterly impossible to avoid using technical terms to some extent. Admitting this, it will therefore be advisable that I set myself at one with the reader by offering some remarks explanatory of those terms, and also of the structural points, which are of the greatest value in descriptive botany as applied to any special group of plants. Amongst *Endogens*, to which large primary division the natural order *Amaryllidaceæ* belongs, there is a much greater difficulty in securing well-defined specific descriptive characters than amongst the larger class of *Exogens*; and peculiarly is this remark applicable to the genus *Narcissus*. It arises from the fact that all the leaves are more or less

narrow, smooth in their margins, and springing from that form of underground stem known as a bulb; in whose formation there is little room for variation, except it be in a matter of size, the slight value of which distinction will be familiar to all botanists. Now, in *Exogens*, we have frequently good, tangible, specific distinctions, derivable from these two sources, with the double recommendation that they readily admit of technical description, and, further, that the distinctive character conveyed in such language is both easily understood and readily applied by the student in the process of investigation. The mere measurement of the several parts must be looked upon as a very doubtful assistance in descriptive botany. Those measurements, which would be applicable to a species growing under one set of cultural conditions, would be totally inapplicable to the same species under another set of conditions; nay, further, such measurements as would faithfully represent the plant development one year, might be perfectly inapplicable to the same plant the next season; the reason of this anyone who knows the extreme variability of our climate (and who does not), and also how much plant growth is affected, beneficially or otherwise, by these climatic variations, will at once comprehend. All the species form shortened stems underneath the surface of the soil, which are known by the title of bulbs; the structure of these may be more readily understood if I define them as buds in which, besides the growing point, there are layers of thick fleshy scales, which act in the two-fold capacity of protective appendages and magazines of nutritious matter, the stem proper of the bulb being merely a flattened axis to which the scales are attached. From the centre of this bulb the leaves arise, they and the flower constituting the fully developed condition of the growing point. The leaves vary somewhat in width, and as they are sharp or blunt at the point, are termed acute or obtuse; sometimes they are round in the section like a rush, at other times flattened, with a slightly projecting keel corresponding with the mid-rib at the back; in colour they vary between dark green, generally the predominant characteristic of the rush-like or cylindrical type, or suffused with a greyish tint to which the term glaucous is applied, as in nearly all the broad-leaved sorts. The term applied to the flower-stalk is the scape; it is either cylindrical or somewhat flattened with a slight wing-like process arising from the sides; in the former case it is termed terete, in the latter ancipitous. The scape is terminated by a spathe or sheath, nearly always of a thin membranous character, and enclosing one or more flowers as the case may be. The peduncle is that portion of the stem extending from within the scape to the base of the flower. Important characters, not unfrequently hinge on the relative length of the spathe as compared with the peduncle; this appears, though constant in similar species, to have a good deal of variability in different species. The flower consists of a combination of calyx and corolla, which in *Endogens*, where they possess great similarity, are collectively termed the perianth. A portion of the perianth is tubular; a further portion is expanded in the form of six lobes or divisions, whose relative length with respect to the tube it is important to notice, as also whether they are separate or developed so closely and in such a manner as to overlap one another at their margins, when they are termed imbricated. Another important character hinges on the angle made by these divisional lobes with the tube; sometimes they are bent back or reflexed; more ordinarily they expand at right angles, or, as in one exceptional instance, they form an acute angle, and thus give the appearance as though the flowers were only half expanded. The corona or crown, whose origin I have already alluded to, possesses some very valuable distinctive characters. Variations occur in respect to its length; on the one hand, it may be but a mere marginal rim, and, on the other, a cylindrical process of much greater length and magnitude than the perianth itself; its upper margin may be smooth and undivided, in which case it is termed entire, or it may have notches, which, when deep, are termed lobes; or it may be frilled, as it were, or have a jagged margin; in the former case it would be termed crispate, in the latter scariosa. It will thus, at once, be evident that this sort of fortuitous growth forms an important element in specific descriptions; and, as I said before, according to its greater or less

development; the whole of the species are divided into three groups. The stamens are six in number, the anthers being supported on stalks called filaments that appear to vary in length according to the size of the corona; where the latter is short the filaments are scarcely developed at all, and usually three only of the anthers are visible in the neck of the tubular part of the perianth, the remaining three being developed at a lower level; where the corona is long and expanded the filaments are well developed, and in that case appear to bend slightly downwards and then curve upwards, to which the term declinate is given. The pistil, whose ovary occurs in the form of a small egg-shaped or lobed green process at the base of the tube of the flower, possesses a style of sufficient length to elevate the stigma to about the level of the three uppermost stamens; sometimes it protrudes beyond, in which case it is termed exserted. This, however, is of rare occurrence.

Grouping of Species.

Though some authors have grouped their species according to the shape of the leaves, I prefer adopting the development of the corona as a more constant character, and, in so doing, follow in Mr. Baker's footsteps, than whom, I believe, no better leader could be selected. To our first group, therefore, the title "large-crowned" fully expresses the fact that it contains all those species in which the corona equals or exceeds in length the divisions of the perianth. The second group—medium-crowned—will include all those in which the crown is about half the length of the perianth; or, in some cases, slightly in excess of that proportion. The third—small or short-crowned—includes all those species in which the length of the crown is less than one-half the length of the perianth; and, in some cases, so much less that it becomes little more than a marginal line.

Group I.—Large-Crowned.

Under this title we have, according to Mr. Baker, but three distinct species, viz. :—

I. *Narcissus Bulbocodium* of Linnæus.—The typical plant upon which Haworth based his genus, *Corbularia*, possesses the

Hoop-petticoat *Narcissus*.

Wavy-leaved *Narcissus*.

following distinctive characters :—The bulbs are ovoid, small, coated with dark-brown membrane scales; the leaves are two or three in number, almost cylindrical and rush-like, of a dark-green colour, rather longer than the flower-stalk; the scape slender and terete, carrying a single partially-erect flower; the pedicels being short and surrounded by the membrane spathe; the perianth gradually widening from the ovary—the divisions linear lanceolate, narrowing into an acute point about the same length as the crown; the crown wide, expanded, or funnel-shaped, the margin circular, almost entire; stamens, six in a double rank; filaments, sufficiently long to bring the anthers to a level with the mouth of the corona, slightly declinate; the pistil exserted. The flowers are a brilliant yellow, little variation occurring between the corona and the perianth. They are produced about the middle of May. This species is known as "the Hoop-petticoat *Narcissus*," a name arising from the similarity of the corona to the fully-distended petticoat of the last century. It is a native of the coast of France, from Bordeaux southward to Spain and Portugal, and occurs also in the north of Africa. Culturally speaking, this is a somewhat delicate species, growing freely in light soil, and especially loving a mixture of peat, loam, and sand on a dry sub-soil. In damp low-lying ground the bulbs are liable to rot off in the winter

time. Amongst the whole of the *Narcissi* we have no more showy plant than the Hoop-petticoat *Narcissus*. It is adapted both for outdoor culture—when the soil and sub-soil suits—and for indoor culture, where the intense brilliant yellow of its blossoms, contrasted with its dark-green leaves, recommend it for spring decoration in the conservatory. It is not, however, amenable to very early forcing, as its blooms are liable to go blind. Amongst the varieties of this species which possess tolerably constant characters, and are in pretty general cultivation, we have four varieties :—

Var. 1. *B. conspicuum*, the *Corbularia conspicua* of Herbert.—It is in all respects a major form, with the margin of the corona slightly wavy, and is synonymous with Haworth's *Corbularia gigas* and *aurea*.

Var. 2. *B. tenuifolium*.—In which the plant is altogether smaller and the leaves more slender and twisted.

Var. 3. *B. serotinum* differs from the typical species, in having a much more widely expanded corona, and broader divisions of the perianth, and in its flowers standing well above the peculiarly twisted foliage.

Var. 4. *B. monophyllum*, synonymous with *N. Clusii* of Dunal.—I have my doubts whether this should not be retained as a distinct species. It differs from all the others in its flowers being almost white, in its producing one leaf only, or in rare instances two, and in its exceedingly dwarf growth. In respect to its cultural peculiarities it stands alone; once only have I flowered it, from bulbs sent me from the Jardin des Plantes, Paris. The past summer is the second during which the same bulbs have laid dormant; not a vestige of growth have they made, and yet they are perfectly fresh. The same remark applies to several bulbs I had from the authorities at Kew three years ago. It is a native of Barbary and the north coast of Africa, where, I

Common Daffodil.

am told, it grows and flowers freely enough. Why, then, should it be so stubborn in cultivation with us? Clearly, some of the special conditions which will warrant success are wanting to us. Perhaps some of your correspondents who have been more successful, or who have seen it growing wild, will kindly favour us with a detailed account of the conditions under which it flourishes in its native habitat.

II. *N. Pseudo-Narcissus* of Linnæus is the true Daffodil, with which we are all familiar from our earliest childhood. It is the typical plant upon which Haworth constituted his genus *Ajax*. The bulbs of this species are egg-shaped, and fully twice the size of the previous one; the leaves are produced in fives or sixes, broad, erect, flat on the upper side, and slightly keeled below, of a greyish-green (glaucous), somewhat shorter than the scape at the time of blooming, but increasing in length afterwards; the scape is about 12 inches high, flattened, and presenting two prominent edges; the flowers, solitary, the short pedicel completely included in the sheath; the tube of the perianth about half an inch long, ob-conical, the divisions slightly spreading, each alternate one rather blunter; the crown, equal in length to the divisions, somewhat plicate at the mouth, and irregularly notched at the margin, the stamens rising in one series from the base of the tube; the colour is yellow, the crown being of a deeper tinge than the perianth; one of the earliest blooming of the *Narcissi*, coming into flower about the middle of March. It is a native of Britain, but rare in Scotland; it is found also as far north as Sweden, and is pretty generally distributed through Spain, Portugal, and Transylvania. Under this species we have five or six very distinct varieties.

1. *Pseudo Narcissus plenus* and *plenissimus*.—The former is the ordinary double variety; the latter, as the name indicates, is a much more extreme form of reduplication; it is much more dwarf in habit and is a variety rarely met with.

2. *Pseudo Narcissus, major*.—Synonymous with Haworth's *N. maximus* and Salisbury's *grandiflorus*. This is, in every respect, a plant of larger growth, besides which the petals are more expanded and the crown wider at the mouth and more crisped than in our typical species; the leaves, also, are twisted. It has been thought by some that the above variety, *plenissimus*, is the double form of this, which I should be disposed to admit, were it not for its markedly diminished stature.

N. Pseudo Narcissus, var. 3 bicolor.—The old *N. bicolor* of Linnæus.—A very handsome variety, differing chiefly in the fact that the

perianth is of a pale lemon-yellow, whilst the crown is a deep golden colour; it flowers nearly a month later than its type, and is by no means so frequently met with in cultivation.

N. Pseudo Narcissus, var. 4. *moschatus*.—Synonymous with *N. cernuus*, of Haworth, and very probably with *N. Sabini*, figured in the *Botanical Register*, possibly the latter may be a garden hybrid. This variety has a similar development to the type, and differs chiefly in the fact, that the flower, in all its parts, is coloured alike of a pale sulphur-yellow, almost approaching to white. Why this name was especially given, I am at a loss to discover, as I have never been able to detect any musky character in its fragrance. In this variety the corona generally exceeds in length the divergent petals, which are more or less twisted.

Musk-scented Narcissus.

N. Pseudo Narcissus, var. 5 *minor*.—This most interesting and earliest blooming of all the Daffodils will be familiar to many under some of the following synonyms: *N. nanus*, *pygmæus*, *pumilus*, and *exiguus*. Its stature does not exceed 5 or 6 inches, and in all its parts it presents the appearance of a diminutive form of the type; how this character has become so confirmed it would be difficult to say; but we find it has altered nothing during three centuries of garden culture, and the figure given by Dodonæus is unmistakably the identical plant of the present day. It is not often one sees a variation so constant. It is a native of Spain. Its neat compact habit, and its early blooming, are characteristics which must commend it for general culture. I am quite disposed to believe that there are two very distinct forms of this minor variety readily appreciable by those who are familiar with them in a living state; but these distinctive characteristics appear, like the acrid poisonous matter of many plants, to evaporate in the process of drying.

III. *N. Calathinus* of Linnæus (*N. reflexus* of Brotero) is quite distinct from that figured in the *Botanical Magazine* under that name. The general appearance of the plant, both as to floral structure and growth, is admirably given in the accompanying figure. The bulbs are not half the size of the preceding species; the leaves are generally in threes, very slender, and of tolerably bright green, and concave on the face. The scape is also slender and rounded, rising to a height of 8 to 12 inches; flowers, one or two on a stem, supported on long pedicels that raise them clear of the spathe, and give them a drooping character. The tube of the flower is very narrow, and, in this respect, quite distinct from the preceding species. The divisions of the perianth are almost oval, tapering off at either end, and completely reflexed. The crown is about the same length as the divisions, tending in shape more to the globose than the cylindrical; the margin is merely indented into six smooth lobes; the stamens are arranged in a double series, but do not protrude into the corona; the colour of all parts of the flower is a pale yellow, and there is some record of a pure white form. It blooms in the latter part of April. This is both a handsome and a rare species, not only rare in cultivation, but also rare so far as its ascertained localities are concerned. Mr. Baker records two habitats, one on the island of Drenec, one of the Glenans, on the coast of Brittany; the other in Portugal, on the authority of Baron Paiva. I once had the true species in cultivation, and flowered it, but it died the following season; nor, indeed, does Mons. Thuret appear to have had much better success at Antibes. A tolerably clear reason for our want of success is to be found in the conditions under which it grows in its wild state. It appears that the short Grass amongst which it is found abundant enjoys the influence of an extremely mild and moist climate, and is also continuously and copiously watered by the salt spray from the sea. It is presumed by some that this island is the only known locality for this interesting species of *Narcissus*.

Reflexed Narcissus.

Group II.—Medium-Crowned.

The crown is about one-half the length of the divisions of the perianth. In this group Mr. Baker enumerates but seven species, five of which only are known as really wild plants, and specimens of which occur in the herbaria from their respective habitats.

IV. *N. triandrus* of Linnæus (the *Ganymedes triandrus* of Haworth), is one of those few specific names in which Linnæus may be caught tripping. The inference one would naturally draw from the name is that the flower possesses but three stamens, and although only that number present themselves at the mouth of the tube, there is a second series, unobservable, a little lower down, which the mechanical opening of the tube at once displays. It would appear that Haworth was as equally at fault as his great predecessor, and adopted the *triandrus* specific character. Possibly the three lower stamens may be sometimes abortive; but in the plants I have grown the six perfectly-developed stamens were evident enough. The bulb is very small, not more than half an inch in diameter, somewhat elongated. The leaves, usually in threes, exceedingly slender and semi-cylindrical, 6 to 8 inches long, of an olive-green; scape, two-flowered, about 8 to 12 inches high, slender; the pedicels of the uppermost flower long, and clearing the spathe; that of the lower one scarcely protruding from it; the tube of the flower slender and cylindrical;

Cyclamen-flowered Narcissus.

the divisions of the perianth lanceolate and reflexed; the crown obconical, with an almost entire margin; stamens in two distinct series, the upper inserted near the mouth of the tube, the lower at a point considerably below; the flowers, both as regards tubes, petals, and corona, are pure white and pendulous. It is a native of Spain, being tolerably abundant in the Pyrenees, where it blooms in the month of April, but in cultivation in this country its blooming season is nearer the middle of May. The figure in the *Botanical Magazine* differs from the above description

as regards colour, as it is there represented of a pale yellow tint. This is, no doubt, the true form of the var. *cernuus*. The exceeding slenderness which characterises all the parts of this plant gives it a grace and elegance which few of the *Narcissi* possess; consequently it ought to be more generally cultivated. It is perfectly hardy, but does not increase so rapidly as other species, and, where planted out, it ought to have a little carefully-prepared light compost for itself. There are several varieties worthy of record.

Var. 1, *pulchellus*, in which, while the corona is white, the divisions of the perianth are yellow. It is identical with the variety *luteus*, as figured in the *Botanical Magazine*.

Var. 2, *cernuus*, the flowers pale yellow, conical, and rather more vigorous in general habit of the plant than in the type. This is no doubt the plant figured as *triandrus* in the *Botanical Magazine*.

Var. 3, *nutans*, is a much stronger-growing plant, in which the margin of the crown is crenulated, not smooth and entire. As figured in the *Botanical Magazine*, it has very much the appearance of a hybrid, between the Jonquil and our present species.

V. *N. montanus* of Lindley is a name under which this species

White Mountain Narcissus.

is more generally known than that of Salisbury, adopted by Mr. Baker—viz., *poculiformis*. It is also the *N. galanthifolius* of Haworth. The bulb is of moderate size; the leaves are broad and flat, four to five in number, and shorter than the scape, which is about a foot high; flowers, usually produced in pairs, drooping, the upper one on a lengthened pedicel; the tube, short and cylindrical; the divisions of the perianth, oblong, lanceolate, often twisted; the crown, slightly expanded at the mouth, moderately plicate and crenulate; stamens, almost sessile, in two series; the anthers, exerted from the mouth of the tube; the flowers are white, and possess a delicate perfume. Lindley supposes this plant to have been introduced from the East, possibly from Smyrna; but Baker distinctly says that it is only known in gardens, and

supposes it to be a hybrid production. Be this as it may, it is a very distinct form, and a free grower, though rarely met with in cultivation. Its fragrance is not the least desirable of its attributes.

VI. N. Macleaii of Lindley, figured in the *Bot. Register*, has bulbs about 1 inch in diameter; leaves five to six, somewhat shorter than scape, broad, blunt, pointed, and bright green, concave on the face; scape about 1 foot high, bearing one or two partially erect flowers; the tube cylindrical, white, tinged with green towards the base; the divisions of a milky-white colour, spreading at right angles to the base of the corona, broad, rather blunt-pointed, and overlapping one another; the crown of a bright yellow, slightly plicate and lobed at the margin; stamens rising from the middle of the tube, nearly in a single row. Like the last species, this very distinct form is only known in cultivation, there being no record of it as a wild plant. It appears to have some resemblance to the bicolor form of *Pseudo Narcissus*, but this arises more from a similarity in colour than from its structure, which is quite distinct. It blooms in the early part of April.

Macleay's Narcissus.

VII. N. incomparabilis of Curtis, in the *Bot. Magazine*, is the type of Haworth's genus *Queltia*, and with it is incorporated his *Queltia concolor*, *Q. ampla* of Salisbury, and *Q. foetida* of Herbert. Bulb, smaller in size than that of the Daffodil; leaves, broad, three to four, distinctly keeled below, and glaucous; scape, compressed, and two-edged, about 15 to 18 inches long, supporting one solitary partially erect flower; pedicel, short, almost included in the large spathe; expanded flower, 2 to 3 inches in diameter; tube, short in proportion, and cylindrical; the divisions of the perianth spreading, slightly imbricated; crown, broadly campanulate and undulating, crispate at the margins; stamens, arranged in one series; style, exserted beyond the stamens. Next to the *Pseudo Narcissus*, this—which is well named the Peerless Daffodil—is one of the commonest in cultivation. Its flowers are yellow, with a deeper tint in the crown. It is in stature one of the tallest of our Narcissi, its handsome flowers waving above the leaves, which they exceed in height by 5 or 6 inches. Though recorded by Parkinson, it appears to have been overlooked altogether by Linnæus. It is an early bloomer, sometimes rivalling in this respect the common Daffodil, and is a native of Spain and France, extending as far even as the Tyrol.

Peerless Narcissus.

Var. 1, *incomparabilis plenus*, the double form with which the juvenile mind has not unhappily associated the idea of "butter and eggs," to which, indeed, the mixture of the two colours within the corona bears no inapt resemblance. Met with in cultivation almost as frequently as the single.

Var. 2, *incomparabilis aurantius*.—This, though long considered a species, must be looked upon as nothing more than a larger form of the type, with lemon-coloured divisions and crown of a deeper orange. There is a double form of this also, which is known in gardens as the Nonpareil.

3. *incomparabilis var. albus*, still retaining the orange crown, but with milk-white divisions of the perianth. This is a very distinct variety, and much rarer in cultivation than either of the former; the double form of this is distinguished by the popular garden name of the Orange Phoenix. Whence its origin I am unable to say.

VIII. N. odoratus of Linnæus.—This is the plant figured in the *Botanical Magazine* as *N. Calathinus*, and is also the type on which Haworth founded his genus *Phylogyne*; of these he described half-a-dozen species, but they are scarcely even entitled to be called variations, at least as I have grown them. Bulb, egg-shaped; leaves, three or four, about 12 inches long, and half the width of those of the preceding species, quite concave on the face, and convex at the back, of a bright green colour; the scape, 12 to 15 inches long, nearly cylindrical, with the slightest angularity at the opposite sides; flowers in pairs, or sometimes in threes; the pedicel of the upper

sufficiently long to clear the spathe, that of the lower short and included; the tube of the perianth much more slender than that of the previous species; the divisions ovate lanceolate, slightly overlapping one another at the lower part, and spreading at right angles with the tube; the crown neither so expanded as that of *incomparabilis* at the mouth, nor so crispate at the margin, but generally notched into six lobes, sometimes deeply so, at other times very slightly. On this character, which, to say the least of it, is a most inconstant one, varying considerably even in flowers on the same plant, Haworth based the several distinct species before alluded to. The stamens protrude somewhat beyond the tube of the perianth, and the style is exserted. The colour of the flowers is a fine clear yellow, slightly increased in depth in the crown. It produces sweet-scented blossoms about the middle or end of April. Native specimens give Spain, the South of France, and Dalmatia as recorded habitats of this species. I have, however, always had a strong notion that in it we have a plant so distinctly intermediate between *incomparabilis* and the sweet-scented Jonquil as almost to point out its origin from this double parentage. It is popularly known as the great Sweet-scented Jonquil, and as such is recorded by Parkinson, and

Sweet-scented Narcissus.

was cultivated by Miller as the larger Jonquil; be this as it may, it appears to retain its characters very constantly in cultivation, as the present plant is identical with the somewhat rude figures of the early herbalist.

1. *N. odoratus var. lætus*, more familiar in cultivation under Haworth's name of *Phylogyne Curtisii*, is a sort of minor form, one, indeed, that approaches more nearly, in every respect, even the shorter-crown, to the Jonquil than the typical species.

IX. N. juncifolius, of Requien, is synonymous with *Requienii*, of Roemer, also *Queltia pusilla*, of Herbert.—The name adopted is decidedly the most characteristic. The bulb in this species is exceedingly small, scarcely $\frac{1}{2}$ inch in diameter; the leaves are quite cylindrical and tapering, of a bright shining green, closely resembling those of a rush, 5 or 6 inches long, and occurring in threes and fours; scape, about the same height as the leaves, quite round and very slender; the flowers are generally two in number, sometimes reduced to one, or more rarely extended to three; the pedicels very short, so that the flowers appear to spring from the

Rush-leaved Narcissus.

spathe; tube of perianth cylindrical, very narrow, divisions freely expanded broadly obovate, each terminated by a little projecting cuspis or point, imbricated at the mouth, slightly notched and considerably broader than deep; stamens, in two series the upper just protruding beyond the mouth of the tube, the lower series some distance down in it, the style included. This species possesses thoroughly well-marked distinguishing characters, but is one of the smallest and

slender growers of all the Narcissi, its flowers are of a bright yellow throughout, and are produced, according to Baker, about the middle of April, but with us they rarely expand before the first or second week in May, and to my mind its diminished stature gives it a special beauty of its own, enhanced perhaps by the fact that it is an unmistakable species. It is a native of Spain and the south of France, and, like nearly all the slender growers, appears

require a mixture of peat in the soil as well as an abundance of sand, a good supply of moisture when in growth, and perfect dryness when at rest; for this purpose a sunny, sheltered corner in the select rockery should be devoted to its culture.

N. juncifolius var. *gaditanus*, I have never seen in cultivation—on it the limb of the perianth is exceedingly short, scarcely as long as the crown; it is, if I remember rightly, figured by Boissier in his Spanish plants, as a distinct species, under the name of *N. gaditanus* but is so closely related to our present species that no doubt Mr. Baker is quite justified in making it a variety.

X. *N. dubius* of Gouan; synonyms, *N. pallidus*, Poir and *Fernione dubia*, Haworth. The bulbs are nearly twice the size of the preceding species; the leaves are from four to six in number, rather broader, channelled on the inner face, and slightly recurved at the margins, as shown in the small portion of the full-sized leaf in the figure, they are also somewhat glaucous, and 5 to 6 inches long; the scape rather exceeds the leaves—it is slender, compressed, and has two marginal nerves well defined; the flowers are two to six in number, the upper ones elevated on long pedicels, considerably exceeding the spathe in length; the tube, cylindrical, narrow; the divisions of the perianth broadly ovate, spreading, or slightly reflexed, blunt-pointed, imbricated; crown, rather contracted at the mouth than extended, slightly crenulated along the margin; stamens most sessile, and, with the style, just protrude into the base of the corona. I have never seen this species in cultivation, being only familiar with it from Moggeridge's excellent figure. The flowers are pure white; and, were it not for its broader leaves and compressed scape, it might, from its small stature and other general characters, be taken for a variety of *juncifolius*. Now that good distinct forms of the narcissi are in such request, and seeing that it grows in the neighbourhood of Nice, no doubt we shall soon have the pleasure of making its personal acquaintance. It is mentioned as growing wild at Nice, well as at Toulon, Marseilles, and Avignon. Judging from its appearance, I should take it to have a much more vigorous constitution than the preceding, and likely to become a more popular plant.

Group III.—Small-Crowned.

Crown, less than half as long as the divisions of the perianth. This, a third group, comprises eleven species, with many of which we are quite familiar in cultivation. If in the preceding sections, it was not necessary to absorb a host of so-called species, in this, the last section, will be found a still greater array to be dealt with, and a still greater reduction to be made.

XI. *N. Tazetta* of Linnæus, and its varieties, stand as representatives for upwards of forty-six of Haworth's so-called species. Amongst the whole number the difficulty is to say which is the original *Tazetta* of Linnæus. The description in his *Species Plantarum* is both short and indefinite; and, though sufficiently definite to enable us to distinguish one of this exceedingly variable section from the other species described by him, still leaves a matter of great doubt as to which is the exact form he had in view. In this state of uncertainty it is doubtful whether it would not have been better to have made the expressly descriptive name *Polyanthus* a representative one; the more so, in popular parlance, all these are known as *Polyanthus Narcissi*, and as they are imported from the Continent in large quantities for forcing purposes, for which their free growth, light and variable colours, and delicious perfume, render them exceedingly well adapted. The plant, figured under the name *Tazetta* in the *Botanical Magazine*, is, I see, referred by Baker to the variety *aureus*, on account of the bright yellow colour of its flowers, which, as well as one or two other characters, appear to identify it

White-flowered Narcissus.

Little-cupped Narcissus.

as the *N. aureus* of Loiseleur. The bulb of our typical plant is large, 2 inches or more in diameter, covered with chocolate-brown membranaceous scales; the leaves four to six in number, broad, flat, bluntly keeled at the back, of a lightish glaucous green; scape, 12 to 15 inches; compressed and furnished with two projecting lines; number of flowers variable from four to eight, all supported on pedicels of sufficient length to raise them clear of the large membranaceous spathe; the tube and limb of the perianth are both white, nearly of equal length, the latter divided into broad imbricated lobes, blunt at the point and extended into a short cuspidate process, more or less clearly defined. The divisions sometimes slightly reflexed; the crown forms a shallow cup-like process of bright golden colour, almost entire or very slightly lobed at the margin; the anthers sessile in a double series, the upper ones just projecting beyond the mouth of the tube. Its habitat extends eastward through Syria into Cashmere, and even into China and Japan—hence the origin of one of its synonyms, *N. orientalis*, which is a most appropriate name. The varieties, eight or nine in number, which appear to be sufficiently distinct and constant to require chronicling at our hands, naturally group themselves into three divisions according to colour. The first includes those in which the perianth is white and the corona yellow. The second those in which both perianth and corona are pure white, and the third those in which the flowers are entirely yellow.

FIRST DIVISION.

N. Tazetta, var. *mediterranea*, has narrower divisions of the perianth, scarcely at all imbricated, and decidedly more reflexed; the bulb also is smaller than in the typical plant.

Var. *polyantha*, as the name implies, produces a great number of flowers in each scape, varying from eight to twenty; the bulb is nearly 3 inches in diameter; it is one of the most vigorous growers in the whole group, and we may take that variety, so popular in our Continental importations, known by the title of *Grand Monarque*, as illustrative of this form.

Var. *ochroleuca* differs from the foregoing in the darker green of its leaves, which are more convex at the back, and not so distinctly keeled. The citron-coloured corona is larger and more entire in its margin, and the colour, as a white, somewhat less pure, hence the name *ochroleuca*.

SECOND DIVISION.

Var. *papyraceas* (the Paper-white Narcissus), has broad glaucous leaves, a distinctly ancipitous stem; tube of the flower, slightly tinged with green; perianth and corona, a perfectly pure white, the latter distinctly crenulate and scarious at the margin.

The Intermediate Narcissus.

Var. *Panizziana*, along with all the purity of colour possessed by the former, is smaller in all its parts, the divisions of the perianth being separate, and not overlapping one another. This variety I only know from Moggeridge's figure. Presuming that the characters are constant, it is a very distinct form.

THIRD DIVISION.

Var. *italica*.—This is the *N. italicus* of the *Botanical Magazine*, a plant of slender growth, producing numerous flowers on a scape; the divisions of the perianth scarcely imbricated, of a pale yellow, the colour of the corona being a similar yellow, a little more intensified; the corona is distinctly six-lobed.

Var. *chrysantha*, a variety with small yellow flowers, not more than 1 inch in diameter; the divisions of the perianth imbricated; the crown a rich golden-yellow, almost entire at the margin.

Var. *aureus*, has flowers as large as *italica*, the petals broad and densely imbricated, of a brilliant yellow; the corona almost entire, bright orange-yellow.

XII. *N. intermedius* of Loiseleur.—Bulbs about an inch in diameter; leaves, three to four, almost cylindrical; of a dark shining green, about the same length as the scape, which is from 12 to 15 inches long. The flowers are from two to five, on pedicels sufficiently long to protrude beyond the spathe. The tube is long and narrow in proportion to the size of the flower; the divisions of the perianth are broadly ovate, narrowing to the point, and imbricated at the base; of a pale lemon colour; the crown of a deeper yellow, plaited, and slightly crenulated; anthers, almost sessile. This

is frequently cultivated as *N. bifrons* and *N. bicrenata*. It is a native of the south of France, Spain, and the Balearic Islands. It gets its title from its apparent close relationship on the one hand to the Tazetta, and on the other to the Jonquil, and combines many of the leading characteristics of both species. If, however, it be a hybrid—as I strongly suspect—it is one of Nature's sports, and enjoys a fairly wide distribution with little or no variation. Mr. Baker records one variety only under the title of *N. intermedius radiatus*, in which the divisions of the perianth are narrower, and, consequently, less imbricated, and the crown also distinctly six-lobed. Synonymous with the *Hermione compressa* of Haworth. This form I have not myself seen in cultivation.

XIII. *N. gracilis* of Sabine, in the *Botanical Register*, is no doubt the same plant as that figured in Curtis's *Botanical Magazine* under the name "tenuior," both of which are very possibly modern names for Wildenow's "*angustifolius*." His description is, however, so indefinitely brief, that it would be rash to conclude what plant he really did mean. Our plant has exceedingly slender bright green leaves, four to six in number, semi-cylindrical, with a deep semi-circular channel on the inner side; the scape rises above the leaves, is slightly compressed, and is usually one or two-flowered; the tube of the perianth is very narrow, the limb dividing into broadly obovate segments, each terminated by a sort of cuspidate point, the whole overlapping one another in a marked degree, and of a very full sulphur-yellow; the crown is cup-shaped, with an expanded margin, slightly plicate and crenulated, of a bright golden colour; the anthers are almost sessile, arranged in two series. This species, though long in cultivation, and having originated, in the first instance, from Holland—a somewhat suspicious source, by the way—has never yet been found growing wild; hence, its claims to specific origin are doubtful. It is more probably a hybrid, with a little of the Jonquil and Poet's *Narcissus* combined in the leaves, and a similar mixture of these two, with the addition of a little Tazetta blood in the flowers. Be this as it may, it has, through a long series of years, retained a very distinct appearance, and to that fact it is indebted for its specific honours.

The Slender Narcissus.

XIV. *N. pachybolbos* of Durieu, as the name implies, has a large bulb of from 2 to 3 inches in diameter, covered with brown rough corrugated scales, differing in this respect from all other species; the leaves are four in number, glaucous, flat, about a quarter of an inch wide, slightly keeled at the back; scape, about a foot high, compressed, and ancipitous; tube, pure white, half an inch long above the ovary, expanded portion of the perianth little more than half an inch across, the divisions blunt-pointed or nearly rounded, much imbricated, and slightly cuspidate, also pure white; crown, saucer-shaped, very shallow, almost entire, and, like all the rest of the flower, perfectly white; stamens, in a double series, almost sessile. This is a modern Algerian species, somewhat closely related to Tazetta, from which it differs chiefly in the exceeding smallness of its flowers, and the rough corrugated character of the outer scales of its bulbs. I am not aware that it is at present in cultivation in this country; but find a memorandum recording it in a list of Algerian plants sent to the garden at Montpellier some years ago, from which I was in hopes to have obtained it.

Great-bulbed Narcissus.

XV. *N. Jonquilla* of Linnæus, is the well-known favourite old Jonquil of our gardens, whose cultivation extends, in this country, over a period of nearly three centuries. The original name given to it by the Spaniards was *Jonquillas*, hence the specific title adopted by Linnæus. Though often confounded in books, especially in old works, with *N. juncifolius* (already described), it is perfectly distinct, possessing, as it does, the exceedingly small crown characteristic of this section, along with a more erect growth of foliage and larger development altogether. Those authors who group the species

according to the leaves would, of course, be justified in placing these two species in juxtaposition. It may appear almost unnecessary to give a description of a plant so well known as the Jonquil; but as it is worthy of a figure, which, by the way, gives a capital idea of the general contour of the plant, it must also be considered worthy of a description. The bulbs are small, scarcely an inch in diameter, more globular than the generality of the *Narcissus* heretofore passed in review, and surrounded with a thin dark brown outer scale; the leaves are usually in pairs, of a deep glossy green, nearly cylindrical with a groove or channel down the face

Common Jonquil.

scape, rather shorter than the leaves, slender and terete, supporting from two to six blossoms; the tube is nearly an inch long, the divisions of the perianth are broadly lanceolate and slightly cuspidate, scarcely at all imbricated; the crown is saucer-shaped, very shallow and slightly crimped at the edge; anthers almost sessile, in two series, the upper just protruding beyond the mouth of the tube. In colour, the flower is throughout its parts a clear golden-yellow, and possesses a delicate and delicious perfume. It blooms about the end of April or beginning May. It is a native of Spain, France, Italy, and Dalmatia. In cultivation, it is by no means so vigorous a grower as many of the other *Narcissi*, and, if left undisturbed for a series of years, is rather apt to dwindle away, the flowers becoming solitary at first, and then

The Greater Jonquil.

The Double Jonquil.

disappearing altogether. There are three fairly distinct varieties, viz. :—

N. Jonquilla plena, the double form which is pretty common in cultivation; but, under unfavourable conditions of culture, is liable to lose its duplex character.

N. Jonquilla major.—Here, as the name indicates, all the parts are larger, and the constitution of the plant appears to be altogether more vigorous—a character which it retains with considerable constancy.

N. Jonquilla minor.—A lesser form than our typical plant, dwarfed in growth—both of foliage and flower-stalks; the divisions of the perianth narrower, somewhat reflexed, and slightly twisted. The latter peculiarities appear to me to indicate that it is something more than a mere weakly form induced by bad culture, to which it has been referred by some authors.

Twin-flowered Narcissus.

bulbs are of medium size, rather above an inch in diameter; leaves about four in number, broad, flat, slightly glaucous, bluntly keeled at the back. The scape is compressed and ancipitous, bearing

XVI. *N. biflorus*, figured and described by Curtis in one of the early volumes of the *Botanical Magazine*, is known as the "Twin-flowered Daffodil," a peculiarity which its expressive specific name at once conveys. I am bound, however, to admit that I have seen it occasionally only once-flowered, and more rarely producing three flowers from a scape.

ally two flowers; the spathe is long and erect, standing well above the pendent blossoms; the tube as well as the divisions of the perianth are of a milky-white colour; the latter expanded, flat, with their margins slightly undulate; individually they are broadly obovate, blunt-pointed, and imbricated; the crown is cup-shaped, deeper than either the preceding or succeeding species, and has a spreading scariously crispate margin, of a light lemon colour; stamens, sessile, arranged in one series, and included in the tube of the perianth. Whether this plant is or is not a real original native of Britain, it is scarcely necessary here to discuss; suffice it to say that Gerard and others of our old writers allude to it as in their time growing abundantly in many of the western counties of England; so, if it be an introduction, it must be considered as fairly naturalised in its new home. It flowers about the end of April, and is very sweet-scented. On the Continent it is abundantly distributed through France, Switzerland, Italy, and the Tyrol. It is of a strong vigorous constitution, and appears to enjoy a long-continued undisturbed possession of a locality, being always happiest when growing near the margin of a wood.

XVII. N. Poeticus, of Linnæus.—The Poet's Daffodil, or more readily recognised by its popular appellation, the "Pheasant's-eye Narcissus," a name derived from the beautiful margin of crimson colour that surrounds the corona, is another of the thoroughly naturalised Narcissi of Britain, and certainly the most classical and lovely of the three, that we lay claim to as indigenous plants. I believe there is some doubt whether this is the original poetic Narcissus, or the *N. poetarum* of Haworth (literally the Narcissus of the poets), but in order to disperse the doubt, if any there be, we roll them both into one, so far as any specific

Poet's or Pheasant's-eye Narcissus.

Double Poet's Narcissus.

ue is concerned, merely recognising that of Haworth as a variation; nor do our absorptive propensities cease there, as we place several others to a similar state of subjection. I hope our friend Mr. Leeds, of Manchester, will look upon our wholesale specific slaughter as endorsed by something more than a mere poetic license—to our description. The bulbs are about an inch in diameter, the ves, usually produced in fours, flat and glaucous, with a blunt point at the back, possessing less substance than those of the last. The scape is about a foot high, or more when growing in a shady locality; flowers solitary, or very rarely produced in pairs; the pedicel short, so that the flower expands just clear of the spathe; the tube of the perianth rather better than an inch long; the divisions obovate, blunt, and slightly cuspidate, moderately imbricated, of pure papery-white colour; the crown is saucer-shaped, very shallow, yellowish at the base, much crisped along the edge, the irregular lines formed being margined with a well-marked line of crimson scarlet; the anthers are sessile, arrayed in one series, some of them projecting slightly into the base of the crown. The Pheasant's-eye Narcissus is deservedly a popular plant. The white contrasts with the tiny crimson margin so perfectly as to make it almost, amongst flowers, the very type of simple modest beauty, such as, no doubt, Narcissus himself was, ere the sight of his own reflection roused his dormant vanity. Those of my readers who have seen a good bunch of the flowers of this Narcissus (100 blooms), all grouped together, intermingled with a few of brown leaves, will, I am sure, agree with me when I say that it possesses a charm which only those who have seen can possibly appreciate, and a fragrance, though perhaps too powerful *en masse* for the conditions I allude to, yet individually the flowers yield a delicious perfume. Our plant blooms about the end of April or the beginning of May, depending, no doubt, a good deal on the character of the season. Besides being naturalised in Britain, it grows abundantly through the south of Europe, from France as far as Greece,

where it is generally found affecting somewhat moist upland meadows. As a number of species are included under *N. poeticus*, so we are obliged to recognise several distinct varieties, and, I am bound to say, very constant varieties too.

Var. 1, *M. poeticus plenus*, the double-flowered form, pretty frequently met with in old-fashioned country gardens, and a great favourite in the old country nosegay. It blooms nearly a fortnight later than the single; and, for any additional beauty it may acquire in the multiplication of the petals—pure as they may be and are—it loses quite as much in the absence of the crimson-margined cup, whose broken fragments may be discovered on a minute investigation; in fact, I take it that, whereas the single represents Narcissus in his simple unconscious beauty, the double form is typical of the ruffled feathers of his conscious vanity, the charm of simplicity having been sacrificed in substituting the questionable one of duplicity.

Var. 2, *radiiflorus*.—This is admitted as a distinct species by both

The Green-flowered Narcissus.

Var. 3, *recurvus*.—This is a late-flowering slender form, in which the divisions of the perianth are reflexed and wavy along the margins. It appears to retain its character very constantly under cultivation.

Var. 4, *Poetarum*, the *N. Poetarum* of Haworth and the poeticus var. *grandiflorus* of Herbert. This is a much larger form than our original type, the flower is nearly 3 inches in diameter, and the divisions overlay one another to a very great extent, and are not at all reflexed. This, I believe, is the plant figured in the "English Botany" as our native type of *N. poeticus*.

XVIII. N. viridiflorus of Schousboc, and the three following species, are all peculiar, in the fact that they are autumnal bloomers. Our present species is figured in the *Botanical Magazine*, and will always have a much higher claim to botanical than to popular interest. Its bulbs are small, almost round, and furnished with a brown membranous covering, each producing one or two terete fistulose leaves, tapering to the point; the scape, slender, terete, one to four-flowered, the spathe rather exceeding the pedicels in length, the tube of perianth gradually narrowing from the top of the ovary to the throat, the divisions narrow, reflexed somewhat as to the margins,

The Elegant-flowered Narcissus.

and *C. intiger* of Haworth, and is a distinct and well-marked species of Narcissus.

XIX. N. elegans of Spach is synonymous with Link's *autumnalis* and Boissier's *oxypetalus*. The bulb is roundish, about an inch in diameter; the leaves generally solitary, sometimes in pairs, developed, contemporaneous with the flowers, flattish and channelled above; scape, very slender, terete, about the same length as the leaves, carrying

Koch and Reichenbach, and is identical with the *N. angustifolius* of the *Botanical Magazine*. Its leaves are scarcely more than half the width of the typical plant, and besides being more slender are twisted; the divisions of the perianth are obovate, that is, wider towards the apex than the base, hence there is, in place of an overlapping a distinct radiation of the various divisions, whence the name. This plant grows abundantly in the Alps of Central Europe, and possesses a specific claim that we are almost loath to ignore.

and slightly incurved at the points; crown, little more than a projecting line, slightly divided into lobes; anthers, sessile, arrayed in a double series; the flowers are in all parts of a greenish-yellow colour, and possess the delicate perfume of the Jonquil. Though little known at the present day, this is no modern species, having been cultivated upwards of two centuries ago by Parkinson. It is a native of Morocco, the coast of Barbary, and also of the salt marshy flats between Gibraltar and San Roque on the northern coast. This plant is no doubt synonymous with the *Chloraster fissus* of Herbert,

two to five flowers; spathe, long, and wide-expanded; the tube of the perianth slender, of a greenish-white colour; the divisions pure white, almost linear-lanceolate, expanded horizontally; the crown, small, of a yellowish tint, almost entire as to the margin; anthers, nearly sessile, arranged in a double series. This species blooms in the month of September and October, and is a native of Italy, Sicily, and Algiers. It is not by any means a common plant in cultivation. I have only bloomed it once, and, were it not for its meagre foliage, it would be very effective, and fully realise the literal meaning of its specific title. It appears, like *Calathinus*, to have a considerable share of individuality as to the circumstances and conditions under which it will grow, and I have a strong suspicion that our climate is not at all adapted to those species of *Narcissus* that are found on the north African coast, nor is this to be wondered at when we consider how distinct are the climatic conditions of the two localities.

XX. *N. serotinus* of Linnæus is synonymous with *N. deficiens* of Herbert. This must not be confounded with the variety of *Bulbocodium*, to which the name *serotinum* was given, as our present plant is not only a distinct species, but a singularly anomalous one from the fact that its blooms are produced before the appearance of the leaves; hence the specific name *deficiens* of Herbert was by no means an inappropriate one. The bulbs are small, little more than $\frac{1}{2}$ inch in diameter, narrowing upward for a considerable length. The leaves are either solitary or in pairs, very narrow, and tapering to the point, convex below, and very slightly concave above, fistulose as to the lower portion, produced after the scape has died down. The scape is very slender, 9 to 12 inches high, terete, terminated by a large erect spathe, from which one

The Late-flowered Narcissus.

or, more rarely, two flowers are produced. The tube of the perianth is slender, the divisions are obovately lanceolate, and distinctly acuminate. The corona small, cup-shaped, with an almost entire margin; the stamens arranged in a double series near the mouth of the tube. The flowers, as in the last species, are white in all their parts. This plant is rarely seen in cultivation, although it appears to have a tolerably wide geographical range, as specimens occur in the herbaria from Spain, Greece, the Barbary States, and Palestine. It flowers late in the autumn, and the fact that the flowers are developed without any foliage must seriously detract from its beauty, although it adds unquestionably to its botanical interest.

XXI. *N. Brousonneti* of Lagasca.—So distinct is this plant from all other *Narcissi*, that in Gay's Herbarium it is recorded under the new generic title of *Aurelia Brousonneti*. Roemer, in his *Amaryllidacæ*, referred it to *Chloraster*, under the specific title *obliteratus*, evidently expressive of the total absence of the crown. This is a character of so much

real structural importance, that I am almost disposed to recognise its claims to a special generic title—the more so, as a glance at the accompanying figure shows that it bears, in the general campanulate character of the entire flower, a very close resemblance to the *Amaryllis*. Mr. Baker, however, retains it under the old genus; and I avail myself of his description, as given in his excellent "Monograph." He says:—"The bulb is ovoid, about the size of a hen's egg; leaves, about four to a scape, 4 to 6 lines broad, about as long as the scape; scape, about a foot high, four to eight-flowered;

Brousonnet's Narcissus.

pedicels, 6 to 8 lines long, shorter than the spathe; tube, 8 to 9 lines long, exclusive of the ovary, under a line thick, greenish at the base, white upwards; divisions of the limb, sub-campanulated, erect, patent, pure white, oblongly lanceolate, about half an inch long by a quarter of an inch broad, narrowed sud-

denly to a bluntish point; crown, almost entirely confluent with the apex of the tube; stamens, biseriate, the lower filaments $1\frac{1}{2}$ to 2 inches long, their anthers just reaching the top of the tube, the upper filaments, $2\frac{1}{2}$ to 3 inches long, reaching half-way up the divisions." I may observe that, in the above description, as compared with the figure, a slight discrepancy occurs in the length of the tube, that of the figure considerably exceeding Mr. Baker's description; and, further, that no mention is made of a very distinct character which markedly presents itself in the figure, in the gradual widening out of the tube upwards to the base of the divisions of the perianth. Mr. Baker states that the specimen in Gay's Herbarium at Kew, is the only one they possess, and that it is noted as gathered also at Mogador by Broussonet, a fact which is recorded in its specific title. Let us hope that some of our enthusiastic *Narcissi* collectors of the present day—such as our friend Mr. Barr—will succeed in introducing this extremely interesting species into general cultivation.

XXII. *N. canariensis* (The Canary Islands *Narcissus*).—This is, perhaps, the smallest-flowered and most slender species known, the name resting on a solitary specimen in the Kew Herbarium, collected in the Canary Islands. It is about 2 feet in height, the slender scape bearing from five to eight, or more, flowers. The latter are barely half an inch across, often only one-third of an inch, and of a pure white colour, except the anthers, which are deep orange-yellow; the perianth segments are ovate-acute, scarcely a third of an inch long, by $1\frac{1}{2}$ to 2 lines broad; the corona is very small, little more than a raised rim, the margins being nearly entire. This portion of the flower closely resembles the same part in *N. elegans* or *N. serotinus*. It is, undoubtedly, a small-flowered form of the Little-cupped *Narcissus* (*N. Tazetta*), and must be referred to the white-flowered or *N. papyraceus* group. Although far from being a showy plant, it is well worth culture, on account of its singularly graceful habit. It has never, so far as I am aware, been introduced to our gardens.

General Cultural Remarks.

In the preceding descriptions of the several species of *Narcissi* I have had occasion to allude, in exceptional instances, to certain cultural peculiarities, which have suggested themselves from the

The Canary Islands Narcissus.

conditions under which such species grow in their native habitats. In addition to these, I conceive that a few remarks on their general culture will not be out of place. With such I purpose concluding my somewhat lengthy article. Let us, then, by way of preliminary enquire under what conditions do we generally find them in Nature? I have already stated that many of the species frequently affect the margin of woods; others, again, those upland meadows in semi-alpine districts, that during the spring are saturated with moisture from the dissolving snow of a still higher altitude; and some are at home in the salt sandy districts that border on the shores north and south of the Mediterranean Sea; more especially do many of the most distinct species affect the north coast of Africa. Though at first sight these several conditions may appear very dissimilar, yet they possess in common one of the most important elements of successful culture. What, then, is this element? It consists of a maximum supply of moisture when the annual growth of foliage and flower takes place, and a minimum supply at the time when the bulbs are ripened off, by which means a period of perfect rest is secured. These are the all-important points upon which the successful culture of *Narcissi*, and, indeed, all bulbous plants depend. Let us analyse the three conditions before named, and see in how far each one of these conditions—although originating from different circumstances—compass the cultural axiom I have stated, and which is, my reader will admit, so far established as to come under that definite title. Those *Narcissi* that grow in woods enjoy during the winter season, when their giant neighbours, the trees, are leafless—a full and abundant supply of moisture; they are, indeed, then perfect masters of the situation, although pigmies when compared with their summer companions. On the other hand, often after they have completed their growth the active condition of the early-developed leaves of the trees is continually removing the moisture from the ground, and thus providing the elements of rest—namely, a complete dryness of the soil. This beneficial action of the trees is further supplemented by the continuous accumulation of humus or vegetable

arising from the annual fall of the leaves, so that they may be said to be not only the protectors but also the nourishers of their vernal companions. If we study for a moment the conditions of those I have described as at home in the sub-alpine meadows, raising their golden or pure white heads, as the case may be, above the green sward, we find more similarity than might at first have been supposed. Here, in spring, the melting snow from the upland regions percolates through the soil, and supplies abundant moisture for the active growth of these, and the whole family of charming spring flowers, with which they are, under such conditions, associated. As summer advances, and the direct rays of an uninterrupted sunshine impinge on the mountain sides, the moisture gradually evaporates, leaving scarcely sufficient to support life in the surrounding herbage, which is always greedy to devour such as may fall to its lot from the passing shower, leaving the bulbs of the Narcissi in a state of rest, ready to be again roused into activity when the autumn rains, coupled with the failing energies of general plant life, allow the ground once more to become fairly moistened. Again, as to those which affect the sandy shores or coast-line of Northern Africa, does not Nature, in her alternate rainy and dry season, prepare, after a more direct fashion, all the elements required? Here, doubtless, the hot arid winds that blow from the Lybian desert rapidly dry up every particle of moisture from the ground; and, under these conditions, the state of rest may be said to culminate. On this fact, coupled with the presence of certain saline matters which these sands doubtless contain, in all probability hinges the difficulty we experience in the culture of the group of highly interesting species that are met with in Northern Africa; added to which, the diminished temperature of our northern latitude renders it necessary that they shall be grown in pots, so as to protect them during the winter's frosts. And anyone who has attempted to grow even our own native Narcissi in pots through a series of years will soon find that, after the first year or two, they lose their vigour; and practice says it is only to be restored by consigning them again to Nature's bosom, under whose fostering care their failing strength will soon become re-established. We must, therefore, admit that our non-success is in all probability attributable rather to our non-appreciation of the conditions to which Nature has adapted them rather than to any inherent constitutional weakness that they possess. Having thus pointed out the analogy that exists between these circumstances, however diverse they may appear at first sight. Let me ask, do we take Nature for our guide in our ordinary garden culture? I fear the reply must be in the negative—at least more generally is this the case than otherwise. We will take the ordinary conditions under which collections of these plants are found, and the first thing we will probably find is, that they are grouped together in a bed or border by themselves. Now this, I admit, is highly desirable, as enabling a ready comparison of the several species or varieties one with another; but, in addition to this grouping, that law and order which is, I also admit, an essential in tidy gardening, demands that no weeds be permitted to invade their sacred allotment, and, consequently, the hoe and rake are in continuous requisition. Now, for a moment, compare this with Nature's treatment; she supplies them with abundant associates in the shape of the greensward or other forms of vegetation—that, full of active life during summer, take up the superabundant moisture; we carefully remove the same, and thus deprive our Narcissus bed of those elements essential to perfect and sustained rest; the result is that in this, as well, indeed, as in the infringement of any of Nature's laws, we gradually lower the constitutional vigour of the plants. Let, therefore, where they are thus isolated, a substitute be found for the weeds in the shape of Mignonette, associated with a few of our gaily-coloured annuals, and, further, let these be cleared off not later than the middle of September, a nice dressing of well-rotted leaf soil being applied and forked in, thus giving the soil time to absorb a fair share of heat from the autumn sun, and to be sweetened by the atmospheric influence. Where they are grown in a mixed border, usually speaking, they will find themselves in close proximity to some vigorous rooting plant, which will answer all the purposes required. The question may here be asked, why not lift the bulbs in early summer and replant in the autumn? Such is the practice with some growers, but I am loath to recommend it for two reasons: the first is, that such a process is foreign to the Book of Nature; the second is, that there is always a liability of lifting some too soon, and of neglecting to plant others until too late, as well as the difficulty of choosing the happy medium between dryness and dampness in the arrangements made for storing the bulbs away. All these things considered, I prefer leaving them to Nature—merely lifting and replanting them about every fourth or fifth year—and be sure that in doing so you anticipate the very earliest stage of root formation, as, if left, as it too frequently is, to November or December, you are sure to affect the bloom for the next

season. I ought to state that when this lifting process takes place, before replanting, the whole of the bed should be well-dressed with old manure, and thoroughly dug or trenched; if the latter, let the ground be moderately well trodden over to firm it, as the roots of all plants—and more especially of our Daffodils—like to fight their way against a pretty solid resistance; and, remember, that the popular notion of lightness in the texture of the soil being beneficial to root development does not always prove true. Amongst this class of Endogenous plants rarely do we find the roots inclined to branch; nay, I might go so far as to say they are devoid of the power of branching, and, as a result, when even the growing point becomes injured, the root not only ceases to elongate, but really ceases to be of any value towards the sustentation of the plant, as decay sets in and the entire root soon disappears. When, therefore, in removal, more than one-half of these delicate feeding processes are virtually destroyed—which is sure to be the case if they are developed even to the length of half an inch—it will not be at all surprising that the plants receive such a severe shock as to cause blind and imperfect flowers. Speaking of the flowers coming blind reminds me that this may originate from another source as well. The beautiful old-fashioned double Pheasant's-eye Narcissus, a favourite with every one, alike for its purity and its perfume, is one especially liable to this when it has been grown for many years in the same locality. This arises from sheer exhaustion of the soil, and may easily be guarded against by a winter's dressing of nice short rich manure, or by a few copious waterings with diluted liquid manure during the spring growth. The former I prefer, as it answers in the double capacity of protector and stimulant. The roots of all these plants are in a vigorously active state during the entire winter. Hence, it is advisable that they should have their stimulating dose early, and that it should be gentle and constant, not spasmodic. If the roots find not the nourishment in the ground, they will draw on the magazine stored in the bulb for the support of the leaves and bloom. And even after this appropriation the roots are unable, through very feebleness, to make good the loss when they are called upon to fulfil the more severe task. Admitting that, under special circumstances, this grouping arrangement must be carried out, I am far from considering it the one I would recommend for general adoption. There is no place where the Daffodil does better or looks more lovely than when springing from the Grass, there, if he nods his head beneath the weight of the accumulated moisture of a succession of spring showers, no taint of Mother Earth tarnishes his purity, nay, rather, he rises again with returning sunshine fresher and brighter for his bath. On our trim-kept lawns, where the very first growth of the green sward calls into existence the noisy rattle of the mowing-machine, groups of Narcissi are not, by any means, happy; but let us ramble beyond the precincts of culture and cast a glance at a group in the open field, or adjacent to some shrubbery where the scythe but once a year steps in to Nature's assistance, and what do we find? Why, what else but congruity and harmony? The leaves rise, green to the tip, from a mass of mingled Moss and Grass, interspersed with the bright brown foliage of the Beech or the paler Oak, whose various tints lend a contrast to the fresh glaucous hue of the Daffodils; but, besides adding to the beauty and harmony of the picture, these adjuncts, combined, have fulfilled the purpose of admirably protecting the buds in their early growth, and now combine to support the slender leaves against the mutilating influence of the wind, and, further, in the decay of the withered Grass and leaves below, are assisting to restore the elements of fertilisation to the soil. Far be it from me, however, to say that I would wish to banish so loveable a flower as the Narcissus from the precincts of the trim-kept garden. Rather let me show where the most fitting locations may be found for it. The margins of shrubberies are amongst these; there are always little indentations—natural irregularities arising from the difference in growth of adjacent shrubs—where the mowing-machine does not come; corners, we may say, still sacred to the scythe. In these, with admirable effect, may our groups of Narcissi be placed, where respect can be paid to their leafage, so that it be not cut over before it naturally fades away. Do not obtrude them on the lawn in scattered patches, where they but marr the quiet repose of the green sward. In the wild garden, whether it be a dell formed by Nature or by the hand of man, whether it be a rootery or a rockery, or a combination of all together our Narcissi will be found at home. There will be presented all the elements of successful culture, and there they will find happy associates in the wood Forget-me-nots, the variegated Dead Nettle, the Wall Cresses, the Aubrietias, and a host of similar plants, not to mention the bright moss-covered nooks and crannies rich in the verdant colour of their delicate tracery; here then may a collection of Narcissi be maintained in a natural condition, each sort grouped by itself, with an unobtrusive number, by which, on reference to your note book, the name and history of each variety may be obtained.

ASPECTS OF VEGETATION.

OLIVE TREES NEAR THE MEDITERRANEAN.

ALL who visit Nice, Mentone, and the Genoese Riviera, for the first time, are struck with the luxuriant aspect of the Olive groves in these districts compared with those in the more exposed parts of Italy, Spain, and the south of France. With the small proprietors of Olive groves situated along the sheltered shores of the Mediterranean, the Olive harvest is perhaps the busiest period of the year, not even excepting the time when the Orange and Lemon orchards are stripped of their golden fruit. Our illustration represents some of those old patriarchal Olive trees that may here and there be met with on the rocky outskirts of the more densely planted groves near the shore. In the south of France (says Dr. Bennett) the Olive tree, however fertile, is a miserable object. It is generally treated as a pollard, is small and dwarfish, and looks much like a mutilated dust-covered Willow. As soon, how-

longevity of the Olive tree, in a congenial climate like that of Mentone, may indeed be said to be indefinite. There are Olive trees still alive at Monaco, at the Cap Martin, and elsewhere, which are supposed to be coeval with the Roman Empire. It is a slow-growing tree, and forms cartloads of hard roots, which fill and cover the ground where it stands. When, after several hundred years, the trunk decays, the bark remains alive. As the decay progresses the tree splits, as it were, into two, three, or more sections. The bark twists and curls round each of these decayed sections, and unites on the other side. Then, instead of the old tree, we have, in its place, two, three, or more apparently separate, although, in reality, all growing from the same root. When these in turn die, new shoots spring up from the old roots, and thus the life of the tree is indefinitely prolonged. The old Olive groves are, from this cause, indescribably singular and interesting, presenting, on every side, evidences of hoary old age. All the stages of growth above described may be witnessed

Olive trees on the shores of the Mediterranean.

ever, as the Esterel Mountains are passed and Cannes is reached, we enter on a different climate, more protected in winter, and more suited to its growth. It is allowed to grow as a forest tree, and at once assumes a dignity and grandeur which quite surprises those who have only seen the stunted specimens of Provence. The Olive tree is only destroyed by a frost of 15° or 16° Fahr., so that it is not injured or killed on the Riviera by exceptional winters, as are the delicate Lemon trees. But the young shoots and the fruit are frozen and irremediably injured when the thermometer falls 6° or 7° below the freezing point. No frost, however, to which this region is exposed, even once in a century, can injure the tree, so that it goes on growing indefinitely, and attains its natural period of longevity, as do with us the trees that are natives of our country—the Birch, the Beech, the Scotch Fir, and the Oak. Like them, it resists the terrible cold of exceptional years, such as the years 1860-61, and re-appears in spring hale and vigorous, when whole armies of apparently naturalised foreigners have succumbed. The

within the space of a few yards; and the partially decayed, partially split, gnarled, twisted, curved trunks are picturesque in the extreme. The healthy full-grown Olive tree is really very beautiful. It is often as large as a fine old Oak, but with fewer limbs and a more sparse foliage. In the variety of the Olive tree generally cultivated on the Riviera, the terminal extremity of the branches hangs down, so as to give it the characteristic appearance of a Weeping Ash or Willow. The predominance of Olive groves gives a peculiar character to the Mentonian amphitheatre and to the Riviera in general. The Olive tree, which is a native of Asia Minor or of Palestine, is the tree of the Holy Land, and is constantly mentioned in Scripture. Thus its presence, as the principal feature of the surrounding vegetation, imparts an Eastern charm to the place. The branches of the Olive tree are not numerous; they spring from the trunk near the ground, or rather the trunk generally divides into two or three branches. The Olive berry ripens in the autumn, becomes black, and begins to fall off the tree in December and January.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

The Potato.—Since 1845, when the disease first broke out, the Potato has been the subject of more discussion than probably any other vegetable in cultivation, yet the practical results gained by such discussions have been infinitesimally small. There are, however, one or two cultural matters, which, if they do not directly prevent disease, at least tend to avert its worst effects. Foremost among these is a selection of such kinds as, from their early maturity, are ready to take up before the disease usually sets in; and next, and scarcely less important, is the preparation of the tubers for planting. Instead of allowing seed Potatoes to remain in clamps, or to lay thickly in heaps in a dark place until the time has arrived for putting them in the ground, soon after the commencement of the year, the earliest sorts should be placed in a single layer in shallow boxes in a place where they will receive sufficient light to cause the sprouts, which are then beginning to form, to grow stout and strong, and of such a nature as will, to great extent, reduce their liability to break off at planting time. This treatment prevents the weakening effects of the tubers forming long weak sprouts, that are certain to be destroyed in placing them in the ground, and it effects the all-important object of giving them at least three weeks' start in advance of such as are planted without any previous preparation. The best varieties for general cultivation are of Kidneys—Myatt's Ashleaf, Veitch's Improved Ashleaf, and Lee's Hammersmith Kidney. The last is early, a heavy cropper, and not surpassed in quality by any early Potato in existence. Of Round kinds—I would recommend Early Oxford, York Regent, and, for the latest, Paterson's Victoria. Any of the first-named Kidneys, and the above three Round varieties, are enough for all practical purposes, while in quality they are immeasurably before the soapy high-priced American sorts. The boxes used for placing the tubers in should not be above 6 inches deep, and enough dry straw should be at hand for protection in case of severe frost. The driest part of the vegetable-ground should be selected for Potatoes, and if the soil be light and poor, some manure should be wheeled on to it when the ground is frozen. This may consist of old hot-bed manure, in which a considerable amount of leaves has been used, or decayed vegetable matter from the refuse heap, which should have a place in or near every amateur's garden, and to which all vegetable tops, leaves, and Grass mowings should be conveyed, as also summer weeds that have not been allowed to grow until seed has been produced by them. In a well-managed garden they ought never to be allowed to stand until they have reached that condition, but, if such a stage has been reached, these, and weeds of a perennial character, prunings and hedge clippings, should all be charred (not burned), and the charcoal added to the refuse heap, which, if well and tidily managed, instead of being offensive to the eye, will become a valuable adjunct to the garden; the cultivator should, as far as possible, return to the soil all that it has produced, so as not to impair its fertility. If in a neighbourhood where lime can be had at moderate cost, a liberal addition of it to the refuse heap will greatly improve its quality, as well as destroy slugs and their eggs.

Peas.—When the ground is not frozen, and a dry moderately sheltered piece exists, a few early Peas, consisting of Sangster's No. 1 or William the 1st, should be sown. The latter is a very free cropper, and both are good for early work. They should be sown in rows 3 feet apart, in moderately rich soil. If at all poor, dig in some manure. The ground for the rows should be opened about 2 inches deep, but the seed should be covered with 4 inches of soil, consequently a slight ridge will be the result, which will assist in throwing off rain. If the ground is at all wet or retentive, Peas will be much benefited by the covering being composed of old potting soil or similar dry material. Scatter over the surface of the rows a sprinkling of fine coal-ashes, which will prevent slugs from infesting the soil, in which they frequently do early Peas serious mischief. These early crops should be sown considerably thicker than further on in the season, so as to make up for loss by birds and other enemies. The seed of these early sorts is much smaller than that of the late varieties; consequently it goes further in sowing—a quart will sow a row of about 10 yards. Where danger is apprehended from mice, an excellent plan is to get some Gorse, clip it with the garden shears to about an inch in length, and scatter it an inch thick over the seed in the rows before the soil is put over them; this also mitigates the effects of severe frost should such occur so as to penetrate the ground deeply before the seed has vegetated, and by which sometimes it is injured.

Seakale and Rhubarb.—If not already done, Seakale and Rhubarb roots should be put in for forcing. It is much more economical to take these roots up for forcing than to force them where they grow. Seakale will do well on a slight hot-bed made of leaves, which are not liable to get too hot. On such a bed place a

small frame, and put into it 6 or 8 inches of ordinary garden soil then put in the roots a couple of inches apart. Instead of the glazed light on the top of the frame, use a wooden shutter, over which place enough old mats or litter to completely exclude light. Rhubarb may be forced in the same way, but it will require a deeper box to allow its growing higher than the Seakale. Rhubarb and Seakale so forced will be found much better flavoured than such as is grown in a Mushroom-house, where a quantity of stable manure is fermenting, and which frequently imparts such a rank taste as to make it unfit to eat.

Glass Structures.—Indoors continual watchfulness will be required, as a few hours negligence may easily destroy the work of a season. When there is any appearance of frost it is safe practice to put on a little fire sufficiently early in the evening to get some heat into the pipes in good time. This, amongst ordinary green-house plants, will be rather beneficial than otherwise, provided the temperature does not rise above 45°, which should be about the heat maintained in such a structure through the night; to be thus prepared is much better and more economical in the way of fuel than hurrying on fire late in the night, when extremes of insufficient or overheating are too often the result. Should frost continue, be careful that the plants are not placed too near the pipes, or they will get their roots dried by the heat; this is a matter of frequent occurrence where open trellis-work shelves exist over the pipes, even if at considerable distance from them, the heat in its upright course rushing right to the plants, unduly exciting growth, and having a most unnatural influence upon the roots. Cinerarias and Calceolarias, more than most things, cannot bear being placed in such a situation; a low pit, if such exist, is the best for these plants, where they can stand on a bed of coal ashes, with a hot-water pipe round it to exclude frost; if a place of this description is at hand, they will make satisfactory progress, and maintain their large bottom leaves in a healthy state. Cinerarias are most useful winter-flowering subjects, but do not well bear heat to bring them on, nor is it necessary; for, if the seeds were sown in proper time, so as to get the plants sufficiently forward, they will come in without using a higher temperature than indicated for the general stock. The deliciously-scented *Daphne indica* should find a place in every amateur's collection, keeping it during the winter at the warmest end of the house, but now, as always, being careful not to over-water it on account of the aversion this plant has to being too wet at the roots. If a few plants of the useful, hardy, white-flowering shrub, *Deutzia gracilis*, are placed at the warmest end of the house they will come on gradually into flower, and be very useful either as decorative subjects or for cut flowers. A few pot Roses may also be similarly treated, but, before they are brought in, see that they are quite free from insects. The continuous flowering Cyclamens are indispensable for winter-blooming; they should be well supplied with water, if they are allowed to suffer for want of it they will not succeed; keep them near the glass, if on a shelf not far from the roof all the better. If, in the amateur's garden, there is a house devoted to Vine culture, and the crop is all cleared, the sooner the Vines are pruned the better, as nothing is gained by deferring the operation; close pruning to a single eye makes the neatest work, but in the amateur's Vinery it will be safer to leave a couple of eyes to each spur; after they are pruned they should at once be painted over with the usual dressing, composed of clay, with a little sulphur, soot, and soft-soap or Gishurst compound, mixed with water, so as to form a thick paint, with which they should be coated all over—previous to which the loose outside bark should be stripped off, but only such as is loose, not scraping them to the extent sometimes practised, and which does serious injury (no doubt with the intention of removing the eggs of red spider or thrips), and is as unnatural as anything that could be imagined. After they are finished they may be tied across the front of the house, especially if young Vines that have not fully occupied the space they are intended to fill, in which case they will require their points keeping tied low down to induce them to break back; if old Vines they may be tied up in their places.

GARDENING FOR THE WEEK.

Trees and Shrubs.

THE present wintry weather will have put a stop to all planting; but advantage should be taken of it to prepare stakes for steadying and supporting any plants that have been recently transplanted, or may require such assistance. Such a lull in active operations will afford time for maturing plans, preparing lists of plants wanted, and for getting ready suitable labels, &c., so that planting may be pushed on the moment a favourable change in the weather takes place. The labour set free from planting may now be profitably employed in trenching and preparing large holes, if the ground has not become

too frost-bound. The snow will, in a great measure, have prevented this; but care should be taken to clear this off the surface before opening the trench, for, if buried in the soil, it is a long time thawing, and considerably reduces its temperature. In severe weather, in the absence of snow as a protector, a load or two of straw-rubbish should be kept at hand to throw over the surface of the ground to be trenched, as it will prevent frost penetrating, and the work of trenching can then be carried on without interruption. In trenching, great care should be taken not to allow any vegetable matter that is not decomposed to become mixed up with the soil, as it is sure to generate Fungus. If it be intended to break up and reform old plantations, all the *débris* should be carefully raked from the surface before disturbing the soil, for, if buried, it is sure to injure the health of the plant. Leaves and dead sticks are generally harmless so long as they lie on the surface, as they absorb and retain too much moisture in this position for Fungus to generate; it is only when buried and moderately dry that the conditions are favourable for its formation. On the surface of the soil the fallen leaves of most plants are a positive benefit, as they gradually decompose, and convey to the soil fresh material for the roots to feed on. Besides the manurial matter they carry back, they are invaluable as conservators of moisture, as they form an excellent mulching, and effectually prevent the escape of moisture. It must be a dry time indeed, if moisture cannot be found under even a slight layer of leaves. Nature does not allow even a fallen leaf or a blade of dead Grass to be lost. Each has its new productive functions to perform; and, finally, in their decay, form food for the nourishment of fresh organisms. At this late season it is better to defer planting all kinds of evergreen till April, unless the plants to be removed are of small size, and are to be transferred to very sheltered situations. The last few mild winters have induced many to continue planting evergreens much too late, and if this has been the case this season, the chances are that many will be killed, for there is every prospect now of a severe season, and the turn of the year will most likely usher in even colder weather. All recently transplanted stuff should, therefore, receive a heavy mulching, so as to prevent the ground about the roots from becoming frozen. In planting very large deciduous trees, the stems and main branches should be bound up, either with bands of hay or Moss, but the latter is preferable, as it is neater and more retentive of moisture. If the trees are to be planted in exposed situations, this protection will be found of the greatest assistance in keeping the bark plump till root action takes place. Many large trees are lost after removal through neglect of this, as the bark becomes dry and contracted, thus closing the channels that should be kept open for the free circulation of sap. If this contraction of bark is allowed to take place, it is one of the greatest checks a tree can receive, and the growth is never so free or satisfactory as would have been the case if the bark had been kept fresh and plump. The necessity for this extra labour will depend much on the size of the tree to be operated on, and the character of the situation it is intended it should occupy, but if large, or at all valuable, it is better to give a little time and attention to this than to run any risk of failure. Plants of questionable hardiness should at once receive protection by shaking a quantity of dry leaves round their base. These should be afterwards covered with Laurel branches or Brakes, to prevent them being blown away. Numbers of shrubs and plants, that would otherwise be killed or greatly injured, will stand severe winters if protected in this way. Take advantage of the first favourable change in the weather to push on the planting of all kinds of deciduous trees and shrubs, for if frost again sets in, it may throw this work too far into the new year. If any trees are received from the nurseries during frosty weather, they should be placed in a close damp shed till a thaw takes place, a measure that will be found much better than exposing them by attempting to plant, or lay in. For ornamental planting, few deciduous trees excel the *Taxodium distichum*, as it is always beautiful, from the first opening of the bud to the fall of the leaf. Its light, elegant, pale green foliage equals in beauty many of the Fern fronds, and might be used to great advantage in lieu of them for dressing out flowers. In the autumn nothing can surpass the warmth of colour the foliage of this tree assumes, and even at this late season the trees are not yet bare. For rich autumnal leaf colouring, the Liquidamber is one of the most striking, and should have a place in every shrubbery, where, associated with variegated Hollies, &c., it will show off its lovely hues of rich colouring most effectually. The different varieties of *Rhus* are invaluable for the foreground, especially the lovely *R. Cotinus*, with its richly-coloured silky plumes, and *laciniata*, which makes an effective plant for the sub-tropical garden. *Ampelopsis japonica* is another desirable plant on account of its richly coloured leaves, and *A. Veitchii* is valuable for covering walls. If planted alternately with white variegated Ivy, the effect is most pleasing, as the Ivy forms a very pretty

setting for the red leaves of the *Ampelopsis*.—J. SHEPPARD, *Wolverstone Park*.

The Flower Garden and Pleasure Grounds.

While the ground remains covered with snow, or in a frost-bound condition, little can, of course, be done in these departments, unless it be the pushing forward, as much as possible, such operations as involve the removal of soil or the wheeling of gravel, compost, and manure; and this can generally be performed more expeditiously during hard frost than when the surface of the soil is soft. Where it is intended to remove overgrown or superfluous trees from the lawns or elsewhere, this may be done during such weather as we are experiencing at the present time. Shrubberies may also be thinned out by the removal of unnecessary plants, but the pruning of the remaining specimens, particularly that of evergreens, should be deferred until March. And when the weather is such as to stop the progress of all operations in the open air, attend to the preparation of stakes, labels, and Birch besoms, &c., all of which will be found useful as the season advances. Many bulbs and hardy herbaceous plants cultivated in the open border disappear altogether during winter, and their crowns are not infrequently injured by being trampled upon, unless they are all distinctly labelled; but where this is not considered necessary, a stout oak peg should be fixed in the centre of each group or patch of bulbs or herbaceous plants of any kind which disappears, and this peg should stand some 4 or 5 inches above the surface of the soil, and will serve to indicate the whereabouts of the plants, and prevent them being injured when the borders are dug or pointed over early in spring. Hardy annuals in pots intended to be planted out early, with the view of producing an early display, should have, for the present, the protection of a pit or frame, and are not unlikely to be injured by slugs or snails, to prevent which they should be frequently examined and occasionally dusted with quick-lime, if found to be necessary. Protect also such winter-flowering plants as the *Chimonanthus fragrans*, *Jasminum nudiflorum*, and the Christmas Rose, which will now be in full bloom if protected by a frame or a hand-glass. Continue carefully to protect bedding plants of all sorts from frost, and, whenever the state of the weather will permit, give abundance of air to dry up damp, &c.; but, at the same time, avoid placing the plants in a cold draught, and do not give water until they are really dry, when enough should be given to thoroughly moisten the soil.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Orchids.

Keep the temperature of the Orchid-house as equable as possible. *Angræcums*, *Dendrobium moniliforme*, and the different varieties of *Calanthe*, more especially the latter, will now be in fine bloom, and the flowers must be carefully treated, so as not to allow them to get wet, or they spot. This is one of the most valuable plants for providing autumn flowers, and possesses the advantage of associating well with any others, and lasting well when cut, if attended to in the matter of water. Do not allow the plants to shrivel too much for want of water, more especially *Vandas* of the *suavis* and *tricolor* sections, or they will lose their under leaves, which, in addition to injuring the plants, destroys their appearance. Keep *Cœlogyne cristata* at the end of the house, where there is most moisture in the atmosphere, and supply it sufficiently with water at the roots. Do not, however, allow any to fall on the advancing flower-spikes, as they are impatient of stagnant moisture. A temperature of from 50° to 55° at night will be enough for Mexican plants. Of these place such as are coming into flower at the warmest end of the house. They will include *Cypripedium insigne* and *venustum* and the varieties of *barbatum*, *Lælia anceps* and *autumnalis*, *Zygopetalums*, and some *Oncidiums*. These will be found invaluable for cutting at a season when flowers are most acceptable. In fact many of these old-fashioned winter-flowering Orchids do not receive the attention they deserve, but have been thrust aside for novelties possessing much less merit. Sponge over all the plants, so as to keep the foliage clean, and remove scale and other insects, which can only be kept under by continuous attention.—B.

Indoor Fruit Department.

In starting Vines, the chief point to be kept in view is a moderately strong bottom-heat to stimulate the roots into action. To ensure this, therefore, form new beds of fermenting material both inside and out on the top of the roots of Vines newly started; make these beds of sufficient thickness to raise and retain a heat of 90°. The inside bed will greatly assist in keeping up the temperature to 55°, which is quite high enough for the first week or two. When a portion of the fermenting material is turned over daily, it gives off a nice soft moisture, which is very beneficial to the Vines during hard firing. Cover the outside bed with glass sashes or boards, to keep out wet and wind, thus economising the heat. Add fresh linings to

outside beds made up a month or two ago, should they need such attention. The root temperature must, on no account, be allowed to decrease at this stage of growth, or a severe check will be the result. The fermenting material may now be removed from the inside of houses which were started in October or on the 1st of November. Tie in the young shoots as they require support; any which have grown in an upright manner should only be brought at first half way into their proper positions, but at the second tying with strong matting, bring them into their right places. Those who propagate Vines in pots put in the eyes about this time. Select the eyes from the best ripened prunings preserved for that purpose, cut the wood straight through directly above the eye, leaving about $1\frac{1}{2}$ inch of it underneath the eye, cut off slantingly, and make an incision opposite the eye, and the operation is complete. Three-inch pots should now be prepared for their reception; these should be dry and quite clean. A few small crocks should be put in for drainage, and the rest of the space should be filled up with good loam. A hole should then be made in the centre of the soil, and filled with silver sand, and the eye should be firmly pressed into position with the hand until the notch made opposite the eye is covered. This will leave the eye only above the soil into which roots will be pushed from the notch. The whole should be gently watered, and then set in some cool spot, from which frost is excluded, for a month before being placed in heat.

Pines.—Another batch of Queen Pines should now be replunged and given increased heat. It will be some time before the bottom-heat gets fully up after plunging them, so that although the Pines first plunged are in a bottom-heat of 90° , those plunged now will be somewhat inured to the increased warmth before the heat has risen to that height about them. The plunging material should be made sufficiently firm to stand up to the rims of the pots until the fruit is ripe. If not previously done, every plant should be thoroughly watered with manure-water immediately the fruit is visible. Smooth Cayenne, Black Jamaica, and Charlotte Rothschild, are the best winter kinds; and, where winter fruit is desired, these kinds should be grown in quantities. Where too many are ripe at once, if the fruits are cut and laid in an air-tight box, they will keep perfectly well for six weeks. Boxes, lined with zinc, are made for this purpose, and should be about every place, as they are useful for preserving other kinds of fruit. When Pines are cut, the old stumps, to which suckers are attached, should be allowed, if possible, to remain where they are for a couple of months, as the present is a very unfavourable time for the propagation of such stock.—J. MUIR.

Hardy Fruit.

This is the very best season for the planting of all kinds of hardy fruit, and, if weather permits, the sooner it is done the better, but on no account attempt to plant when the ground is in a sodden condition. Do not plant too deeply—if a young fruit tree does not thrive, I always trace the cause to deep planting; as a rule, they should never be planted deeper than they originally were in the nursery. After planting, mulch with either rotten dung or litter. This mulching is of the greatest importance, for, in the first place, it protects the roots from drying winds and frost; and, secondly, it manures the ground. The pruning of Apples, Pears, Plums, and Cherries should be done as opportunity offers; and, in the case of strong growers, it may be necessary to root-prune to get them into a fruitful condition, which operation is best performed by entirely lifting and replanting trees of a manageable size, and in the case of larger ones, digging out a trench a reasonable distance from their stems, and gradually working round them, taking care to cut the tap roots especially. For the benefit of those readers who may be intending to plant fruit trees, I give a list of the best half-dozen kinds of Apples:—Blenheim Orange, Wellington, Alfriston, Ribston Pippin, Cox's Orange Pippin, and Cellini; of Pears, Marie Louise, Duchess d'Angoulême, Josephine de Malines, Winter Nelis, Gansel's Bergamot, and Glou Morceau; of Plums, Jefferson, Green Gage, Golden Drop, Orleans, Belgian Purple, and Victoria; of Cherries, May Duke, Late Duke, Bigareau Napoleon, Governor Wood, Black Heart, and Morello. I recommend delay in pruning Gooseberries and Currants, as, frequently, the birds make such havoc of them when the buds first begin to swell and immediately after severe weather, that it is better to wait till food is more plentiful for the birds than lose the entire crop by early pruning. Strawberry beds that were trimmed and dug in the autumn ought now, if not previously done, to be well manured, leaving the dung on the surface of the ground as a protection to the plants. Draining, levelling, soil carting, and otherwise preparing ground intended for fruit trees, may be done when the ground is not in a fit state for planting, and advantage should thus be taken to forward all operations of this nature in anticipation of the busy time approaching.—W. WILDSMITH, *Heckfield, Hants.*

Kitchen Garden.

The seedsmen's catalogues, now coming in, remind one that the sooner all seed-orders are made out and sent in the better; and upon this subject I should like to say a few words. In the first place, it does not pay to buy cheap seeds. Inferior seeds have more to do with the production of inferior crops than is generally supposed. The seeds from one grower may be equal in germinating power to those of another, and yet, from the absence of care in selection, they will produce an inferior crop. Breed always tells in seeds, in fact, in anything, and it is impossible for a seed-grower who takes pains in selecting his stock to sell as cheaply as the one who does not trouble himself about the matter, and whose only criterion of quality is their germinating power. In ordering the seeds for the coming year, as a rule, reliance should principally be placed upon old well-tried varieties; at the same time, in order to keep pace with the times, a few of the novelties annually introduced, may be tried. I do not attach very much importance to high-sounding testimonials; and one thing is certain, a good many of the new or so-called improved kinds of vegetables are not heard of after the first year or two, which would not be the case if they were endowed with all the good qualities vouched for by their sponsors. It may be said that gardeners, in their selection of the occupants of the kitchen garden are very conservative, and I admit there may be some truth in the statement. Fashion has not yet laid her encroaching hand upon the vegetable department, except it may be to line the central walk with flowers; but I never yet knew a gardener, however old-fashioned in his ideas, who would not gladly avail himself of any really improved variety of vegetable; but when a man has been deceived a few times he becomes suspicious, and waits for a new introduction to be thoroughly tested by others before he commits himself. The wealthy amateur is the seedman's best customer for novelties, and fortunately that numerous and enthusiastic class is being constantly reinforced. Take advantage of the present wintry weather to finish wheeling the manure to uncropped land; place it in large heaps in the centre of the plots, to avoid loss from the drying influence of the atmosphere, and do not level it down till just before the land is in a fit condition for digging. Prepare fresh stable manure and leaves for making hot-beds by thoroughly shaking and mixing the material together. Where leaves cannot be readily obtained, it will be a very great advantage in making hot-beds if cow or pig-manure can be had to mix with the stable-manure. Horse-manure is hot and fiery, and the addition to it of about one-third, or even a fourth, of its bulk from the cow-shed or pig-stye—which is of a cooler nature—will cause the heat to be more steady and permanent. Where hot-beds are depended on for the first early Cucumbers, a bed large enough for a one-light frame should be put up now for raising the young plants, should no other means exist for bringing them forward. In cold situations, where it was not thought desirable to sow Peas in autumn in the open air, preparations should shortly be made for fetching up lost time, by sowing some under glass for planting out when the weather becomes more favourable. They may either be sown in 48-sized pots or in troughs, which any unskilled workman, who has a few rough boards, can put together, or they may be sown in fibry squares of turf, hollowed out in the centre. It is not advisable to start them in too high a temperature, as there is plenty of time without undue forcing. A frame placed on a bed of leaves, where they can be near the glass, will do well, or, if more convenient, they may be placed in any house where forcing has just commenced. Early Long-pod or Dwarf Cluster Beans may be sown rather thickly in boxes, and brought on gently and strongly under glass, to be planted out singly on a warm border when the weather is suitable. Early Potatoes for hot-bed planting may now be started in boxes or pots, according to the demand and conveniences for growing them.—E. HOBDAV.

Cottagers' Gardens.

Kitchen garden operations must now be regulated by the state of the weather, as the cultivation of land, especially when of a heavy character, or in a saturated or frozen condition, would be positively injurious, advantage should be taken of hard frosts for wheeling manure, soils, &c., to wherever they may be required. Prepare Pea sticks, stakes, labels, &c., during rough weather, in order that no delay may occur when the season for cropping has arrived. Fruit trees or bushes, infested with insects, should now be divested of Lichen and loose bark, and painted with Gishurst compound or other insect-destroying mixture. Mulch the roots of freshly-planted trees with rough litter. As regards flowers, Primulas and Cyclamens should now form conspicuous objects in windows, and a few of the earliest bulbs should be gradually brought forward to succeed them. Christmas Roses, now coming into bloom, will be benefited by receiving some slight protection from unfavourable weather, as their pure white blossoms are easily injured.—J. G.

WATSON'S PORTABLE BOILERS.

THESE are extremely useful contrivances, either for heating halls, libraries, small conservatories, or greenhouses. One of the greatest drawbacks to heating by means of stoves is the dryness which their use occasions; but in the stove of which the accompanying is an illustration especial provision is made to avoid this evil, the action of the fire being more than counterbalanced by the moisture given off by an evaporating pan placed above the water Jacket boiler. The hot water from the boiler escapes by a small flow-pipe, about an inch in diameter, into the pan above, and, as it cools, it descends again by a return pipe into the boiler, an arrangement by means of which a constant circulation is kept up. Thus all the advantages of hot-water heating are obtained on a small scale and at a minimum cost, both as regards the apparatus and the fuel consumed. There are two or three outlets and hot-water pipes can be attached if desirable, so as to distribute the heat more regularly in plant-houses; or these can be plugged, and the boiler then answers every purpose of an evaporating stove. The portability of the apparatus, the short time in which it can be fixed ready for work, and its moderate price recommend it to all who desire a heating apparatus of this kind. It would be useful in any establishment in case of accidents with the

Watson's Portable Boiler.

ordinary boilers and pipes, and as these generally occur when the greatest pressure is upon them, that is during sharp weather, serious damage is often done before they can be repaired.

Salt for Roads and Drives in Frosty Weather.—It is the practice on the North Metropolitan Tramway, and I have myself tried it on other roads with great success, to sprinkle rough salt upon the surface of the roads and in the grooves of the tramway whenever, through snow or frost, the roads became dangerous or difficult. The effect is that within twenty minutes of the application the snow or frost thaws, and horses travel over the roads without roughing and without difficulty. The cost of this process, compared with the loss usually sustained by accident, delay, and the cost of roughing horses, is not worth consideration. One ton of salt costs from 22s. to 29s.; it will, if judiciously applied, thaw about 2 miles of road, and will serve from two to three days of moderate frost. I am aware it is alleged that the salt destroys the adhesiveness of the road surface when a natural thaw comes, but I am also informed by practical men that the same effect upon the roads always follows from the break-up of frost; but, admitting that some slight damage is done, surely the immense advantage gained from the roads being kept open is more than an equivalent for any expense that such damage would entail.—A. G. CHURCH, Secretary, London General Omnibus Company, in *Times*.

THE FRUIT GARDEN.

GRAPE VINE TREATMENT AFTER PLANTING.

LEAVING the subject of temperature to be fully discussed when we come to describe the second year's treatment, which will embrace a complete season's growth, I may only remark here, that in the daily temperature, the maximum should be reckoned at noon and the minimum at sunrise, and go on to speak of newly planted Vines from eyes, which, in my last chapter, we left enjoying a night temperature of 65°, and 80° by day. These figures are only given as averages, however. Supposing the temperature of the Vinery to stand at 85° at mid-day, my practice would be to reduce air gradually and shut the house up to its maximum temperature about two o'clock p.m., sustaining it by fire heat if needful, and allowing it to subside gradually to 75° at dusk, to 65° about ten o'clock, and to 60° in the morning, or even to 55° in cold weather, rather than resort to hard firing. This practice is not troublesome; a little experience soon enables one to judge how much fire-heat is necessary to counterbalance the out-door temperature under all circumstances. As the Vines progress, and the days lengthen, the night and day temperatures should be raised by degrees until about June or July, when the minimum night temperature should not fall much below 70°, and the day temperature should be run up to 80° in dull weather, and to 85° or 90° with sun-heat; shutting up the house on such occasions 5° above these figures, but making some abatement for the night temperature at the same time if the nights are cold. For such varieties as the Muscat of Alexandria and Barbarossa a temperature 5° higher all over will be required. These temperatures should be maintained until the canes get brown and hard to their extremities, which will be towards August or September, according to circumstances. After this the temperature should decline at the ascending ratio, till fire-heat is discontinued and the house thrown open altogether.

Temperature of the Border.

If the border is heated by any of the means before described under the head of "Bottom-heat," the temperature should be maintained during the growing season at about the mean temperature of the Vinery at all stages; thus, supposing the minimum night temperature of the Vinery at starting time to be 40°, and the maximum day 75°, the mean would be 57°, omitting fractions. The mean, however, should not be exceeded; it is better to be under than above it. Where hot-water pipes are employed they should be used with the greatest caution, and air drains should be opened only during the warmest part of the day, and when the temperature is considerably above the temperature of the border. Borders under fermenting materials should always be tested by thermometer 18 inches below the surface of the soil, or where the roots are known to be, and, when the heat is too violent, treading the litter well with the feet will always lessen the fermentation quickly, while turning and mixing the materials, and, when necessary, adding to them, will increase the heat.

Airing.

Closely connected with temperature is the question of airing. Air, less or more, should be admitted to the Vinery at all times, except when the weather is so cold as to necessitate closed ventilators in order to maintain the required temperature. When hot air ventilators are employed, it will be easy to admit fresh air in the coldest weather, but these will not be sufficient on sunny days, and the ordinary back and front shutters will have to be worked. Beginning in the morning with the rising thermometer, all good practitioners make it a rule to admit air little by little, at both back and front, until the maximum amount is reached with the noonday temperature; after which the air is reduced by degrees, until the house will bear shutting up at or above the maximum temperature as before directed, but the ventilators should never be closed altogether; about a $\frac{1}{4}$ inch of air should be left on along the top and bottom. To make sure of this, when the Vineries are in charge of different individuals, I have a piece of thin lath tacked on temporarily under each shutter to prevent it closing entirely. Of course, the scale cannot be adjusted so nicely as is here supposed, but the principle indi-

cated should be held in view. Quick rises and falls of the temperature, or sudden gusts of air rushing in against the foliage, are evils that will surely tell upon the Vines in the long run. In warm weather, such as we sometimes experience in June and July, it is advisable to leave the ventilators wide open day and night. Shutting up should only be resorted to to economise sun-heat, but when the temperature can be kept up without such aid it is in every way better.

Damping.

This is a term generally used to denote a practice necessitated by the use of artificial heat; though at one time damping and steaming was carried to such an extreme in the culture of the Grape, that one might suppose it was absolutely essential, and that the Vine delighted in an atmosphere in a continual state of saturation; whereas, exactly the opposite is the case—a balmy, dry atmosphere, with abundance of moisture at the root, is probably the most favourable condition that could be conceived for the Vine; but under glass, and the influence of fire heat, an artificial state of aridity is produced, especially in sunny weather, which is very trying to the tender foliage of the Vine, and the only preventative is damping, in a discretionary way. For instance, most gardeners know how difficult it is to steer clear of danger on those occasions, when the pipes have been made hot in the prospect of a dull day, and the sun suddenly and unexpectedly shines out in a forenoon, accompanied, perhaps, with a cold, dry, shrivelling wind, which makes it dangerous to open the ventilators more than a few inches; while, on the other hand, danger is equally imminent from a too high temperature, unless air be given. In such a dilemma damping is the safeguard, for a liberal sprinkling of the inside borders and paths with water, which, quickly evaporates and loads the atmosphere with moisture, reduces the temperature and lessens the necessity of giving more air. For similar reasons, damping is also necessary when a Vinery is shut up at a high temperature in the afternoon. A moist atmosphere arrests the excessive perspiration from the foliage, which would otherwise take place in a high and dry temperature, resulting in what is usually called burning, or scorching, of the leaves. Damping, in fact, should always be resorted to in drouthy weather, especially if the leaves of the Vines are observed to be flagging under a bright sun, or to sustain the necessary degree of moisture in the air when hard firing is required. The evaporating troughs on the pipes may always be kept full, as they will only give off moisture according to the heat of the pipes, and consequently supplying the greatest quantity of moisture when it is most needed. Syringing the Vines should never be practised with a free circulation of air, but only when the house is closed, otherwise the effects will be destructive. As far as possible, soft water should be used for syringing. If the rain water from the Vineries is collected into tanks inside the Vinery, it will afford a supply for this purpose; and the slightly sooty character which water so collected always has will be no disadvantage to the Vines if the water is allowed to settle before using it; soot is disagreeable to the insects which infest the Vine. In dull weather, when little ventilation can be afforded, damping in any form should be avoided, as it only induces a watery growth and tender foliage, which flags before the first bright sunshine.

Watering.

Inside borders want a good deal of attention in watering when the Vines are growing, and it is chiefly a question of judgment. With young Vines, whose roots have not extended far into the border, each plant must be watered separately at first, and the whole border should be kept in a sweet and moist condition. The roots rapidly extend themselves, however, when the Vines have fairly started into growth; it is then better to deluge the border thoroughly with water at the temperature of the Vinery, whenever watering is supposed to be at all needful; it is hardly possible to overdo it in this respect when the border is well drained.

Training of the Permanent Vines.

Formerly it was the custom to stop young Vines after they had grown about half-way up the rafter, and to restrict their growth generally, from this period until the end of the season,

in the belief that a stronger cane was thereby secured; but more recent experience has shown conclusively that the contrary is the case—that the greater the amount of wood and foliage the Vines are allowed to carry, the greater their vigour will be—i.e., a Vine which is allowed to make a cane 20 feet long the first year, will be twice as strong as one that is allowed to make only 10 feet of growth. Consequently, it has become the practice with many noted Grape growers, to permit young Vines from eyes to develop both leaders and laterals to their fullest extent; and with one-year-old Vines to let nearly every bud which breaks grow to the top of the house—in fact, to ramble as much as they please; and at the end of the season, to cut the leading canes down to the bottom wire, and the others close back to the stem. The second year, the accumulated energy thus secured is directed into one or two rods only, and canes of great vigour are the result, and these are again cut down to within 2 or 3 feet of the previous year's cut, and so on, till the Vines have covered the roof. There can be no question whatever of the results of this system; but the advantages are more apparent than real, if early return is an object, and not merely sensational bunches at the end of four or five years. The explanation is simple. When this extreme extension system is followed no supernumeraries can be grown, for the permanent Vines occupy the whole of the space. For instance, I have seen a Vinery nearly 100 feet long and 20 feet wide, in which the Vines were trained in this way, and the whole roof, a perfect thicket of wood and foliage, affording a remarkable example of the growth and vigour which can be got up in a few months; but it was the fourth or fifth year before even a partial crop of fruit was secured, whereas such a house should have accommodated at least forty supernumeraries, not including the back wall, without interfering with a moderate but sufficient development of the permanent Vines; and, at the most moderate estimate, at least 400 lb. weight of Grapes should have been gathered the year after planting from the supernumeraries. For these reasons I practise and advocate a medium system of extension with young Vines. I train only one rod from each Vine, which is allowed to grow to the top of the house, when it is stopped, and the side laterals also are stopped at every joint. This single rod permits of sufficient development of wood and foliage to ensure as vigorous a cane as anyone can desire, without encroaching on the supernumeraries, whose welfare are just as important while they are wanted as the others. At the end of the season the canes are cut back to within 2 feet of the bottom wire if they are vigorous (weak growths should be cut down to the bottom again). This ends the treatment of the permanent Vines the first year.

Supernumerary Vines.

As these are only intended to remain till the permanent Vines come fairly into a bearing state, they must be treated with an eye to fruiting the year after planting, and for a few years following. The front row of plants which, it will be recollected, were planted between the permanent Vines, should be allowed to grow about 7 or 8 feet up the wires, and then stopped; the laterals also must be pinched regularly at every joint; the middle row will catch the wires at this point, and they must also be stopped when they have got nearly to the top of the rafters, and otherwise treated in the same manner. The little winter pruning required by these consists in simply cutting the laterals close back to the permanent buds—which should, at the end of the season, be hard and plump—and in shortening back each cane to within 6 feet or so of the point where they first catch the wires.

J. S.

(To be continued.)

ROOT-PRUNING PEACH TREES.

THERE often seems to be considerable difference of opinion as to the practice of root-pruning Peach trees, some asserting that there is no necessity to have recourse to the practice, provided young trees are properly planted in a border adapted to the requirements of the Peach, and every attention of course paid to the regulation of growth, the balance of sap in the tree, and all the necessary pinching and tying, as well as to the cropping of trees in time to prevent a too luxuriant growth. No doubt there are conditions of Peach

culture under which there is little necessity for root-pruning. But, unfortunately, it does not always happen that young trees have their wants supplied, as in the case here referred to. I have before my eyes a number of young trees which have been planted for some years, and yet have never borne anything beyond a chance sample of fruit now and then. The aspect—an east one—is not the best; the border was made of materials calculated to produce an immense quantity of roots, which, in their turn, sent forth vigorous spongy-green wood, to ramble at its pleasure all the summer, and to be cut out the following winter—and so on year after year. The material in which those trees were planted consisted of peaty soil, leaf mould, and rotten manure, the very thing to save one the trouble of gathering much fruit. In the month of June last, when those trees came under our charge, we commenced pruning, which was done at three different times. All strong fruitless wood was cut out, and only that which was likely to be of use encouraged. So diligent were we in the matter of regulating and pinching, that we shall never need to apply the knife in a single instance this winter. It was six weeks before we managed to get the border thoroughly drenched. The neglect, on this score, would account for the long pointed puny buds, which the trees made in previous years. Borders, composed of such light materials as I have named, require any amount of water, more especially in a case like ours, where the tree roots are all inside, and the house a lean-to with a sharp pitch. During the end of the summer the numbers of suckers which pushed up indicated something wrong below, and it was, therefore, decided to mend the old border or make a new one altogether, to root-prune and re-plant. The trees realised every expectation when we got to the bottom, and found the long knotty roots which no soil but leaf mould will produce; and, strange to say, the only two trees in the house which had any fruit whatever on them, were nearly overrun with Fungus. In fact, the whole border, when opened, smelt like a Mushroom-bed. In lifting the trees, care was taken to have a close house, and to dew the roots and tops with a fine syringe. I fancy when these roots get hold of a pure loam instead of leaf-mould, they will, if we may judge from appearances, repay us for our labour by a moderate crop next year. I wish, by these remarks, to convey to the minds of those who hesitate to try root-pruning, that, in my belief, it is the only effectual remedy in cases such as I have mentioned. Peach trees, that are twenty years old, will bear lifting if the operation be carefully carried out, and they are not subjected to very early forcing the following year. I had two large trees of Royal George lifted in the early Peach-house at Roby Hall, which were started to have ripe fruit by the 20th of May; the consequence was, that I gathered dozens of unusually large fruit, for that variety, from trees which, for three consecutive years, had not borne half-a-dozen Peaches each. The practice was also adopted in a late house with the same beneficial results, and so pleased is my successor, Mr. Lindsay, with the change for the better in the trees, that he has given them all a thorough overhaul, and now very wisely intends giving them a comparative rest, which will have the effect of invigorating the trees, and must eventually prove of much benefit.

W. HINDS.

Otterspool Gardens, Liverpool.

HYBRIDISATION OF THE MONUKKA AND BLACK HAMBURGH GRAPES.*

THE Black Monukka is a Grape believed to be of Indian origin, which was received from the late Mr. Johnson, gardener at Hampton Court, and distributed by the Royal Horticultural Society. It is a Grape of great peculiarity and of great excellence. It is of exceedingly robust growth, and a somewhat shy bearer. The bunches produced are, however, very large—from 12 to 20 inches or more in length, and of a regular tapering form. The berries are small, long-ovate, inclining to be conical like an Acorn, measuring $\frac{7}{8}$ inch in length and $\frac{5}{8}$ inch in diameter. In colour it approaches black when well ripened, but is more frequently of a dull reddish-brown; it has a thin coating of bloom. The skin is thin, adhering to the pulp, which is firm, fleshy, and not melting, yet very tender and full of juice. It contains no perfect seeds, only one—or at most two—half-formed, and these being soft like the pulp are eaten with it, as well as the skins. The flavour is rich and sweet, of the most agreeable character, not in any way peculiar, yet refreshing and pleasant to the palate. The Black Monukka is termed a seedless Grape. It is so, however, only so far as the seeds remain immature. The seeds are formed, yet from some cause they are not perfected. This failing may perhaps in some measure account for the smallness of the berry. The peculiarity may possibly be due to defective setting. Were the seeds perfected

and fully-grown, as in other Grapes, the berries would perhaps be larger. Whether this is so or not, however, to alter its peculiar character in this respect would certainly not improve it. There is something very novel and quite pleasing in eating Grapes without being troubled with either skins or seeds. With the view of being able to introduce some of the desirable qualities of the Black Monukka into our most approved sorts, or of raising a good large-berried Grape of a seedless character, such as a seedless Black Hamburgh, it was proposed to try the effect of hybridisation. The necessary and proper precautions being taken to ensure success, a few flowers each of the Black Hamburgh, Muscat of Alexandria, and Royal Muscadine were fertilised successfully with pollen from the Black Monukka. Unfortunately, in thinning the Grapes the few fertilised berries of the two latter were cut off and so lost. But from the Black Hamburgh some twenty-five seeds were secured. The reverse of all these crosses was tried also, viz., using the Black Monukka as the female, but without success. Several half-formed seeds were secured from the Black Monukka, more fully-developed than in their usual normal condition, but they refused to vegetate. From the twenty-five seeds of the cross between the Black Monukka as the male and the Black Hamburgh as the female, twenty-two plants have been raised, fifteen of which have fruited. The first noticeable fact is the foliage. The leaves and shoots of the whole set more closely resemble that of the male parent than the female. The leaves are all deeply lobed and sharply serrated, like the Black Monukka, the leaf-stalks red and hairy, as well as the young shoots. The plants bear no resemblance whatever to the Black Hamburgh; by the foliage they would be grouped as four distinct varieties. In the fruit they are widely different of the fifteen which have fruited; eight of them have the berries white, and five have the berries black; six have long or ovate berries, and seven have the berries round, part of each being black and part white. Three are very early, and two are very late, and, with one exception, they are all small. Two of them have small berries, resembling the Black Hamburgh (female parent), with the leaves of the Black Monukka; one resembles the Black Monukka in the shape and appearance of the berries, but it is a coarse late Grape. Two of them have proved seedless, like the Black Monukka; but the berries are round, and the one white the other black. In no case is there an exact reproduction of either the male or the female parent, the majority of the results being decidedly inferior to either. A few have peculiarities which entitle them to further trial, but the greater part are quite useless.

Best way of Furnishing Walls with Pear Trees.—

“Enquirer” would probably find Pear trees trained cordon fashion, either vertical or oblique, produce fruit sooner than any others that he could fasten to his wall. It would, I think, be a bad use to make of a south wall to plant pyramids in front of it. I have not tried cordons, but I have obtained a speedy and abundant return from trees on the Quince stock, trained to a west wall, in the form of a five-tined fork without its handle, and set upright with the points upwards. Such trees can be had from most nurserymen who are fruit-tree growers. The sorts that have done best with me, so trained, are Louise Bonne, Beurré d’Aremberg, Passe Colmar, Beurré Diel, Beurré d’Amanlis, Soldat d’Espérin, and Doyenné Boussoch. These, when I got them, were maidens on the Quince stock, some from the Chilwell nurseries near Nottingham, and some from Sawbridgeworth. A Glou Morceau on Quince roots, planted at the same time and trained in the same way, took a longer time than the others to arrive at a bearing state; and although the tree looked healthy, and now produces an average crop, the first Pears that appeared were neither large nor good. A standard Glou Morceau on the Pear stock, planted here about five and twenty years ago, attained a large size before it yielded fruit. It has lately produced heavy crops. If I had a south wall, and wished to cover it with Pear trees, I should plant at the required distances trees trained in the form of Verrier’s Palmette, with flat standards or riders between each, to give fruit for a few years, to be reduced gradually, and finally to be removed when the Palmettes had completed their growth.—B. S. [Mr. Tillery advises our correspondent to add to his list of Pear trees Josephine de Malines. At Welbeck this variety is unequalled as regards its rich aromatic flavour, and it generally keeps well from February to May. Planting Pyramid Pear trees in the way mentioned on purpose to get a crop the second year would, he has no doubt, be successful, but the trees would look out of place so close to the wall. It would be better to plant the wall with diagonally-trained Cordon Pear trees on the Quince stock, which, by summer pinching, would yield a good crop the second or third year. They might be planted as close together as 16 or 18 inches, and would produce larger and finer fruit, and a better crop than could be obtained by any other system of training.]

* By A. F. Barron, in *The Journal of the Royal Horticultural Society*.

THE KITCHEN GARDEN.

BROAD BEANS.

THE following is Mr. Barron's report on Broad Beans grown at Chiswick in 1874, as given in the "Journal of the Royal Horticultural Society:"—

The collection, composed of about fifty packets (a great portion being duplicates), was sown on March 6, in very deeply-trenched fresh soil, in lines 3 feet apart. Notwithstanding the dry season, the Beans continued to grow well, and kept free from blights. The trial was in all respects a satisfactory one. The committee awarded two first-class certificates, and reduced the number of varieties to twenty. A further trial is necessary to test their hardiness during winter. For this purpose the seed should be sown in the month of November. The following is a list of the donors:—Messrs. James Carter & Co., Holborn; Mr. J. Douglas, Loxford Hall; Messrs. J. Hardy, Bures, Essex; Minier, Nash, & Nash; Nutting & Sons, Veitch & Sons; MM. Vilmorin, Paris; Messrs. Waite, Burnell, & Co.

1. **Long-pod, Early Long-pod.**—Plant of a very free habit of growth; branching at the ground, with from three to five stems, about 2 feet 6 inches high. Pods, 7 inches long, with three to five medium-sized Beans. Ripe seed, dull fawn colour. Prolific. A general good cropper, and of good quality. Early.

2. **Hang-down Long-pod, Matchless Long-pod, Monarch Long-pod, Feve de Marais grosse Ordinaire.**—A somewhat larger and more prolific variety of the Long-pod, having the full-grown pods much inclined downwards. Ripe seed, dull fawn.

3. **Carter's Mammoth Long-pod.**—A very superior variety of the Long-pod, with very large long pods. First-class certificate.

4. **Green Long-pod.**—Differing from the ordinary Long-pod by the colour of the Beans, which are, when fit for use, bright green. Pods, from 4 to 5 inches long, mostly erect, containing from three to four Beans. Ripe Seed, dull green.

5. **Feve Julienne.**—Plant, robust, 2 feet 6 inches high. Pods, about 4 inches long, narrow, containing about three small Beans. Ripe seed, small, dull grey. Worthless.

6. **Feve Julienne Verte.**—A green-seeded variety of the preceding. Comes into use two days later than Long-pod.

7. **Mazagan, Early Mazagan, Hative de Mazagan.**—Plant, vigorous, with three to five stems, 3 feet 9 inches high. Pods, produced abundantly, erect or upright, 4 inches long, with three to four small Beans. Comes into use five days later than Long-pod, and is the latest of all.

8. **Hardy's Pedigree Windsor.**—Plant of robust growth, 2 feet 6 inches high. Pods, produced abundantly, generally curved downwards like the Long-pods, from 5 to 6 inches long, with three large broad Beans. This seems to be an intermediate variety between the Long-pods and Broad Windsor Beans, and will probably be found to be the Old Toker Bean. An excellent sort.

9. **Windsor, Broad Windsor, Improved Broad Windsor, Westbury Prize, Taylor's Windsor.**—Plant, of full and robust growth, branched. Pods, produced abundantly, much curved downwards, 4 to 6 inches long, about 1½ inch broad at the lower end, with two to three very large broad Beans. Ripe seed, large, dull fawn colour. This is a much-esteemed sort, and of most excellent quality.

10. **Thick Windsor.**—This is distinct from the preceding, in having thicker seed in a ripe state.

11. **Harlington Windsor, Loxford Windsor, Broad Windsor (Veitch).**—This is a well-selected and somewhat improved form of the Broad Windsor, producing rather larger pods.

12. **Green Windsor.**—This is distinguished from the Broad Windsor by having the seeds green. It is, on this account, greatly preferred by some. Ripe seed, large, dull green.

13. **Seville Long-pod, Feve de Seville (Vilmorin).**—Plant, moderately robust, 2 feet high; does not branch so much as other sorts. Pods, very long, 7 to 8 inches, rather sparingly produced, with about six Beans of about the same size as the Long-pods; they hang down so much as almost to rest on the ground. Ripe seed, large, dull fawn colour. This is the earliest and longest-podded of all the Broad Beans. Is fit to gather three days before the Long-pods, and eight days before the Mazagan. It is of good quality. First-class certificate.

14. **Feve Violette grosse.**—Plant of robust growth. Pods 6 inches long, with three to four fair-sized Beans. It is fit for use three days later than the Long-pod, the young Beans being of a pale red colour. Excellent quality. Ripe seed rather long, of a dull violet colour.

15. **White Blossom.**—Plant robust, 2 feet 9 inches high. Blossom white. Pods 4 inches long, with three fair-sized Beans. Ripe seed small black. This is five days later than the Long-pod. A moderate bearer.

16. **Red Blossom.**—Plant robust, with three to five stems, 2 feet 6 inches high. Blossom deep dark red, with black lip; extremely ornamental. Pods 4 inches long, with three fair-sized Beans. Ripe seed is spotted dingy brown. Fit to gather same time as Long-pod. It is much subject to sport, the colour of the flowers varying from deep red to pale dingy brown and nearly black. A moderate bearer.

17. **Feve tres naine Rouge.**—Plant robust, branching much, about 12 inches high. Blossom of the ordinary character. Pods 4 inches long with three small Beans. When fit for use tinged red. Comes into use the same time as the Long-pod. The ripe seed small, dingy red. An inferior sort. Moderate cropper.

18. **White Fan, Royal Dwarf Fan.**—Plant robust, much branched, 18 inches high. A most profuse bearer. Pods produced in erect clusters from the surface of the ground, from 3 to 4 inches long, with about four fair-sized Beans. Ripe seed small, dingy fawn colour. Fit for use two days after Long-pod. A very excellent variety and good quality.

19. **Beck's Dwarf Green Gem.**—Plant robust, but particularly neat and compact; much branched, 1 foot high. Pods small, produced in erect cluster, abundant, about 3 inches long, with three small Beans of a fine green colour. Ripe seed small, green. Fit for use one day after Long-pod. A most desirable variety to cultivate, the crop secured from these dwarf Beans being quite equal to that from the tall forms.

20. **Naine Hative.**—A very inferior form of the preceding.

LIST OF THE BEST VEGETABLES.

Brussels Sprouts.—Strymger's Giant and Roseberry.

Beet.—Henderson's Pine-apple, Dell's Crimson, and Waterloo.

Beans.—Dwarf Cluster, Early Longpod, Green Windsor, and Taylor's Broad Windsor.—French: Osborn's Forcing, Newington Wonder, Canadian Wonder, and Negro Long-pod.—Scarlet Runners and Eclipse.

Kale.—Cottager's and Green Curled or Scotch.

Broccoli.—Snow's Winter, Cooling's Matchless, Miller's Dwarf, Knight's Protecting, Chappel's Cream, and Cattel's Eclipse.

Cauliflowers.—Early London, Veitch's Autumn Giant, and Walcheren.

Celery.—Ivery's Pink, Sandringham White, Williams's Matchless Red, and Incomparable White.

Cabbage.—Enfield Market, Cocoa Nut, Atkins's Matchless, and Red Dutch.

Savoy.—Dwarf Green and Early Ulm.

Carrots.—French Horn, James's Intermediate, and Altrincham.

Cucumbers.—Telegraph and Wood's Improved Ridge.

Endive.—Green Curled and Batavian.

Cos Lettuce.—Dummick's White Victoria, Bath (black-seeded), London White, and Incomparable.

Cabbage Lettuce.—Tom Thumb, All the Year Round, Neapolitan, and Hammersmith.

Leeks.—Musselburgh and Ayton Castle Giant.

Melons.—Gilbert's Victory of Bath and Shah of Persia. The latter is a scarlet-fleshed variety, raised by Mr. Gilbert, and sent out last season. It is of medium size; and, as regards flavour, first-rate.

Onions.—White Spanish, Brown Globe, James' Keeping; and for autumn sowing, White Lisbon, White Tripoli, and Giant Rocco.

Peas.—Ringleader or First-crop, William the First, Dickson's First and Best; Huntingdonian, an improved Champion of England, sent out some years ago; McLean's Best of All, G. F. Wilson, Ne Plu Ultra, and British Queen.

Radish.—French Breakfast, an Olive-shaped variety, good for all seasons; Wood's Early Frame; Black Spanish, for autumn sowing; White and Red Turnip.

Parsnips.—Hollow-crowned and Student.

Tomato.—Trophy and Earley's Defiance.

Spinach.—Round for summer, and Prickly for winter.

Turnip.—Strap-leaved Stone, very early; Red American Stone; Orange Jelly and Chirk Castle Black Stone, for standing the winter.

Vegetable Marrow.—Moore's Vegetable Cream, and Long White.

Capsicums.—Long Red, Long Yellow, and Red Chili.

Cress.—Plain and Curled.

Mustard.—White.

Garnishing Plants.—Parsley: Myatt's Curled; Variegated Kale, and Curled-leaved Mallow.

Herbs and Sundries.—Chervil, Basil, Savory, Marjoram, Thyme, Cardoon, Rampion, Salsafy, Scorzonera, Seakale, Asparagus, and Chicory.

Of course, many other excellent varieties might be added to the above list, but those I have enumerated are all good, and may be obtained anywhere at reasonable prices.

E. HOBDAV.

King Koffee Savoy.—Like Mr. Gilbert, I had a packet of this new dwarf Savoy sent me by Mr. Harrison, of Leicester, to prove for him. I had a quantity of it planted in a plot by the side of Tom Thumb Savoy, and found that it was nearly as dwarf as that variety, and that it had larger heads. Since the frost has set in I have had some of it boiled, and find it to be excellent in flavour, the taste being something like that of Brussels Sprouts. Owing to its growing so near the ground and taking up so little room in the rows, it is a variety that I can highly recommend both for hardiness and general excellence.

—WILLIAM TILBERRY, *W. Elbeck.*

THE GARDEN IN THE HOUSE.

DISEASES IN ROOM PLANTS.

THE normal deep green colour of the leaves in plants is a sign of good health, but a yellowish or whitish tinge, instead of the usual shade, is a sure sign of disease. Unsuitable soil, stagnant moisture, insufficient nutriment, and too much or too little light, all induce this change of colour. In its early stages this disease can be easily cured by the removal of the causes which produce it. When the first signs of discoloration are observed (and they appear first on the leaves of the youngest shoots), the plant should be taken out of the pot in order to examine the condition of the roots. If these are all healthy and fill the balls well, then the cause must be looked for in an insufficient supply of food, or it may be that the plant receives too much or too little light. Want of food may be remedied by shifting the plant into a larger pot, by growing it in richer soil, or by watering with liquid manure. Plants accustomed to grow under the influence of full sunshine produce leaves of the deepest green; while the same plants, if grown in a shady position, generally have leaves of a lighter colour, becoming almost whitish in comparative darkness. On the other hand, plants which naturally grow in shady places, such as Ferns and Selaginellas, if removed into bright sunshine, will have the lively green of their leaves changed into a yellowish hue. Even underwood shrubs often lose their lively green in full sunshine, and plants grown in pots are more liable to suffer in this respect than strong specimens grown in the open air, which are better able to withstand the full force of the sun. Whether too much or too little light be the cause of discoloration in foliage, it can be easily remedied by shifting the position of the plant. If, when a plant is taken out of the pot, the ball is not well filled with roots, and if the young roots have not a fresh healthy appearance, then the discoloration will have been produced by unsuitable soil, or by an excess of moisture. In this case, the first thing to be observed, when the ball is not well filled with roots, is to water cautiously, and to see that the drainage outlet is not choked up, and, if no new roots have pushed into the soil around the ball, the soil must be changed at once. When the soil is suitable and free, and the drainage good, pot-plants do not so easily suffer from excessive watering, but when this is not the case, even in a slight degree, discoloration is almost sure to ensue. Therefore, when the leaves begin to turn yellow in plants which have made but few new roots in the ball, the drainage must be looked after, and the saucer, if any, under the pot removed, or the water, at least, poured out of it after each watering. The plants should, also, not be watered before it is ascertained that the ball is perfectly dry. There are many plants which thrive in almost any soil, and others which, when placed in unsuitable soils, never send out a single young root beyond the old ball. Of the latter kind are Camellias, Rhododendrons, and Epacris. Transplanting into proper soil is, in this case, the only means of restoring the leaves to their natural green colour. If, in the cases in which unsuitable soil, bad drainage, or excessive watering is the source of discoloration, the cause be not removed in time, then follows the second stage of the disease, in which the soil becomes sour, the young roots rot, and the leaves of the young shoots turn yellow. The remedy then is to cut away all the decayed parts of the roots, to transplant into freer and richer soil, to have perfect drainage, to water cautiously, and to give the plants a good position, favourable to their growth, or, if the disease has not very much advanced, it will sometimes suffice to provide good drainage, and to water sparingly with tepid water. By the discoloration of the leaves, the functions of receiving and assimilating nutriment are disturbed; therefore a minimum supply of food should be given until fresh roots have been formed, and the leaves have recovered their normal colour. Watering with warm water, after the drainage has been looked to, tends to remove from the soil the hurtful sourness which has been produced through the stoppage of the drainage outlet, and, in cases where the disease has not made much progress, will be of service, by restoring the soil to a proper condition of sweetness. But, when the disease has already made

great progress, the plant must be taken up, and all affected roots cut back to the sound wood. In still worse cases, the soil of the ball must be shaken out entirely, the roots cut back, and the plant re-planted with some powdered charcoal or sand round the roots, and, outside of this, some loose soil. Rich soil should not be given until the plant has recovered. Discoloration is sometimes also the result of low temperature. The leaves of Orange trees, for instance, often turn yellow in summer, when continuous wet weather or cold winds prevail. It is chiefly, however, plants from warm latitudes, which suffer from this cause, and the remedy consists in removing them to a warmer and more favourable position. Decay of the roots may, likewise, sometimes occur in consequence of too great dryness. Plants, which are kept too dry during their season of growth, soon lose both leaves and young shoots. The loss of the former re-acts on the young roots, and they also perish. Disease may also often be produced by injudicious watering, such as at one time giving so little that the lower part of the ball is not moistened, and at others giving so much that the ball gets saturated. The general falling-off of the leaves, which precedes the season of rest in deciduous plants is a well-known and natural phenomenon, and, after it occurs, the plants require a lower temperature and less water for some months than they have hitherto had. Many evergreen plants grown in rooms, however, often shed their leaves in quantities. This is usually the consequence of the plants being placed in a position at a distance from light, or it may follow from the effects of a dry atmosphere acting upon plants just brought in from a warm moist plant-stove. A well-lighted position, careful watering, and, later on, cutting back the plants to the last year's wood, are the means to be used in order to effect a cure. Plants sometimes die off suddenly in consequence of the partial decay of the stem immediately above the roots, while the roots themselves, shoots, and leaves, remain quite fresh-looking and healthy. This is produced by watering plants which stand in the full sunshine and which have both pot and ball then very much heated. The sudden lowering of the temperature and the absorption of a considerable quantity of water by the plant produce a stagnation of sap where the roots join the stem. The upper part of the plant is thus starved. Tender evergreen plants, especially Heaths, are liable to this disease, which should be guarded against by ceasing to water when the pots are heated by the sun. The pots, however, should be screened from bright sunshine. Rotting of the crown also follows when plants, which have become dry when sent from great distances in summer, are placed with their balls in water, or are watered too copiously, and suddenly brought from a condition of extreme dryness into one of extreme humidity. The proper treatment of such plants should be to place them in the shade, and to water them sparingly at first, gradually increasing the supply of water as they recover from their dried-up condition. Mildew is a disease which is apt to appear on Roses when forced. It spreads in the form of a number of minute white threads over the leaves and buds of the young shoots, spoiling the appearance of the plants, and producing a partial or total loss of the leaves. The white thread-like mycelium always appears at first in the shape of globules, which afterwards spread. In many cases they continue in what is termed the oïdium state without developing into the second form of fungus. This is almost always so in the case of the Rose-fungus, which should not be allowed to spread, but should be extirpated on its first appearance. When the first traces of it are seen on a plant, they should be carefully washed off and the whole plant should be sprinkled with warm water in which some flowers of sulphur have been stirred up, or the leaves should be well dusted with the sulphur when wet, and after it has been on them for a day or two it should be washed off. M.

Limekiln Heating.—Mr. John Cowan is not quite correct in stating that the system of limekiln heating used by him has nothing in common with that originally invented by me; for his, like mine, consists of a boiler heated by a limekiln. They certainly differ strikingly in detail; but Mr. Cowan errs with regard to the chimney. I never stated anywhere that I did not use one, and, in point of fact, I had one attached to my first kiln years before his invention was patented.—ALEX. COLLES, *Mill Mount, Kilkenny.*

Should Hot-water Pipes be Full or Three-parts Full?

—In heating conservatories and churches by means of hot water, should the pipes be full or only three-parts full, in order to allow the water to swell? My particular case is that of a church, which I wish to warm effectually. We have one of Sugden's independent conical boilers, 4 feet high, 15 inches in diameter, with one cross tube, and about 260 feet of 4-inch piping. The boiler is placed about 3 feet below the floor, and at the two highest points we have small taps to let off the air. The supply-cistern is about 16 feet above the pipes; but the chimney has no draught. Will the pipes work best full or three-parts full?—PETER SETTLE, *Whitehaven*. [The pipes should be kept quite full, otherwise the water will not circulate properly. You can easily ascertain if your pipes are full; for, in that case, the water will overflow at your air-taps. The supply-cistern should be kept about half-full, as about half the depth of an 18-inch cistern will be ample space to allow for the swelling of the water in your apparatus. Of course, the water should not be allowed to boil, but only kept hot. If your pipes dip under any doorways or passages, and rise up again on the other side, that will tend to impede the circulation of the water. The want of draught in the chimney may possibly be caused by its being choked with soot, especially if there are any bends in it. As it is impossible to say exactly what is wrong in such a case as yours without inspection, we would advise you to have the apparatus examined by a competent hot-water engineer. The boiler you mention ought to heat the amount of piping named; but we cannot say whether the piping is sufficient to heat the church or not without being made acquainted with its size.]

Periodical Flow of Sap in Trees.—Baranetzky, of the Observatory at Kieff, has investigated the periodicity of the bleeding of certain plants and its cause. Hofmeister was the first who recognised that this phenomena was one very widely observed among forest trees, and the daily and annual periods of this flow of sap have been examined into by several persons. Among the newer results arrived at by Baranetzky, it may be mentioned that he has been able to show that the daily variations of temperature had but little to do with the flow of sap, the latter being as decided in trees protected from temperature variations, by being inclosed in the hot-houses of the botanical gardens, as in the trees of the open air. The variations are perfectly regular, attaining their maxima and minima on the same day and at the same hours, and seem to him to indicate that the influence of temperature on the periodicity of the bleeding is, at least by certain plants, not direct and immediate, but of such a nature that it at first becomes manifest some time after the action of that which causes it. By introducing an artificial temperature variation, this idea was brought to a severe test, and it was shown that the temperature had really but little to do with the flow of sap, although it would be hasty to conclude that it had no influence whatever. It is only in the case of great temperature variations (for instance, a change of 20° Fahr.), that the normal rate of flow of sap is sensibly disturbed.

Fertilising Aucubas.—In your number for the 5th of December you have remarks (p. 525) on this subject. They seem to apply, however, to small or pot plants. Having more than a dozen large female plants about my grounds, I procured three years ago a male plant with plain green leaves. This I planted near a large spotted female, and when both were in flower, though the male was going off, I struck the male flowers against the females, and succeeded in getting a fair quantity of fruit, not only on the one plant, but on several others similarly treated. Next year I followed the same plan—the male having grown and produced more blossom—with the same success; but I had the pleasure of seeing many branches out of my reach bearing fruit, and of course naturally fertilised. Last spring I left the female plant first mentioned quite alone, and the consequence is a splendid crop of fruit in bunches from a dozen downwards; but, besides this, two other large plants in a line with it, probably 30 and 60 feet from the male plant on the side next to it, have fruit set in the same way. The inference is that leaving Nature to herself is the best plan, and that the pollen will do its duty at a considerable distance. When using the male flower artificially I throw the flowers I have been using into the middle of the plant, and I have put fresh flowers into a bottle and suspended them in the tree. Of course I have raised young plants, but am saved that trouble by self-sown ones, of which I have one or two, and expect to see an abundance next year. I do not consider the flowers insignificant, but very pretty.—G. B., *Bath*.

Rat-proof Wire Fences.—In the description given of these fences, at p. 596, the upright bars are reported to be an inch apart; permit us to state that they should not be more than half an inch apart, the former mesh being sufficiently large to let a good-sized rat through. We have made large quantities of fencing of the closer mesh, which fully bear out all that is stated as to their being perfectly rat-proof.—J. J. THOMAS & Co., 362, *Edgware Road*.

NOTES AND QUESTIONS.

[THE following notes and questions came to hand, or were answered, too late for insertion in their several departments.]

Onion Seed for an Acre.—Can anyone tell me how much seed is required to sow an acre of Onions for pickling? What would be the average produce? What soil is best? And what would be the cost?—STREATHAM.

New Type of Pelargonium.—In the remarks on this subject, translated from the *Revue Horticole* and published in our columns last week (see p. 581), for Mr. Charles Haller, of Nice, read Mr. Charles Huber, a correction for which we are indebted to Mr. Jean Sisley, of Lyons, the writer of the article in question.

Schizostylis coccinea.—I can endorse all your correspondent has said (see p. 539) in favour of this plant; here it was in bloom till the 7th of last month, when the rain and frost spoiled the remainder of the blossoms. Not only is it useful for outdoor display, but, when grown in pots, it is of great service in the embellishment of the conservatory. I ought also to add that, as a cut flower, it will keep perfectly in water for some days.—J. C., *Tyenham*.

Wintering Alocasias.—What do you consider the best way of treating Alocasias in winter? Are they to be dried off like Caladiums, or kept moderately moist? I should like to know particularly about Lowii, metallica, zebrina, and macrorhiza.—AN AMATEUR. [Winter your Alocasias in a warm plant-stove, keeping them rather drier at the root than when growing. The kinds you name are evergreen, and must not be dried off like A. Marshallii, A. Jenningsii, and other deciduous species.]

Fittonia argyroneura an Edging for Shelves.—For concealing the bare edges of stone shelves this plant is extremely useful. I have seen it grown in many places, but I never saw it cultivated in such perfection as it is in the plant stoves at Drumlanrig. There it is grown in nothing but half an inch of gravel, which is placed upon the shelves to set the pots on, and so luxuriant is its development that it hangs down 2 feet below the top of the shelves, and forms a rich and beautiful screen of silver-veined foliage.—J. MUIR.

Aucuba japonica dicecia.—In Mr. Maurice Young's catalogue, under the head of "New Aucubas," I see announced a variety, "Dicecia, having male and female on the same plant." I know not whether this is merely a grafted form or whether it is a true variety, but it is undoubtedly incorrectly named. The common Aucuba is dicecious, that is, has the two sexes on distinct individuals; plants with the male and female on one plant, but in separate blossoms, are termed monœcious, and monœcia would, no doubt, be a suitable name for Mr. Young's variety.—G. S. BOULGER.

Grapes Travelling without Packing Material.—In reference to this subject, allow me to say that, last autumn, I sent several hampers of Grapes packed as is described in your last number, from Jersey to Scotland. The sorts sent were Black Hamburg, Lady Downe's Seedling, and Golden Champion; this last, I was afraid, would not travel safely, as both the bunches and berries were large—in fact, they looked as if the less they were moved the better; but they arrived at their destination in good condition. The entire quantity sent, I was informed, had travelled better than any hitherto sent carefully packed in tissue paper, which was wrapped round each bunch, the interstices being filled in between with cotton wadding.—R. P. B.

Winter-flowering Orchids.—The following Orchids are now in bloom in the Victoria Nursery, Holloway, viz.:—Lycaste Skinneri and lanipes; Masdevallia ignea and Veitchii; Maxillaria venusta, nigrescens, and picta; Odonoglossum Andersonianum, Bluntii, cordatum, grande and rubescens; Oncidium cucullatum and tigrinum; Phalænopsis amabilis, grandiflora and rosea; Anæctochilus ordianus; a new Burlingtonia; Cymbidium Mastersii; Cattleya superba splendens; Calanthe Turnerii, Veitchii, vestita lutea-oculata and V. rubra-oculata; Cypridium insigne, javanicum and Roezlii; Dendrobium McCarthiae; Epidendrum prismatocarpum, vitellinum, and dichromum; Lælia autumnalis and anceps superba; Saccolabium giganteum; Stanhopea tigrina; Vanda tricolor Dodgsonii, flava, and insignis; and Zygotum Mackaili.

The Stockwell Green Building Agitation.—Within the past ten days or so the question with respect to building upon Stockwell Green has assumed an entirely new phase; it now appears that the demand made for the land, by the alleged freeholder—originally £4,000, next £8,000, and now finally said to be £12,000—has led to Chancery proceedings, which may ultimately result in establishing the fact that Mr. Abbott, who sold the ground to Mr. Honey for building purposes, had, after all, no legal right to do so, and, if so, that Mr. Honey's title is consequently bad. Should this eventually turn out to be the true state of affairs, the despoiling of the Green, which has been in progress during the last few weeks, may prove a serious matter for those responsible for it. It appears that the work of dismantling going forward at the early part of last week caused such an amount of irritation amongst the inhabitants as to have almost led to a breach of the peace. This was during the cutting down and removal of two of the finest trees on the Green, and the clearing away of a considerable portion of the turf. The other day the case came before the Master of the Rolls, on an application for an injunction in the suit of "Hammerton v. Honey," when the Master of the Rolls, upon an *ex parte* statement, granted an *interim* injunction restraining the defendant, the lord of the manor, from building upon or enclosing the Green. The effect of this judicial order is, that the Green must not further be disturbed until the case is legally argued on both sides, which will not take place before the middle of this month.

OBITUARY.

WE have to record, with much regret, the death of Mr. Charles Norval Thompson, son of the late Mr. Robert Thompson, for many years superintendent of the Royal Horticultural Society's Gardens, at Chiswick, at the early age of forty. For fourteen years he was sub-editor of one of our oldest horticultural journals; his genial disposition and unobtrusive manners, while in that capacity, gained for him many friends, and few enemies. He leaves a widow and four children indifferently provided for.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

TRANSPLANTING OLD FRUIT TREES.

HAVING seen many remarks lately on the transplanting of trees, and the effects of mulching and other treatment in promoting success, and in improving the health of the subjects operated upon, the following account of an experiment, on a somewhat extensive scale, which I made a few years ago with aged fruit trees will, perhaps, be interesting, as showing what may be accomplished in this direction with good prospects of success. It is often desirable to remove old fruit trees on an estate, but the fear of failure as frequently prevents the operation being carried out—more especially if the trees in question are favourites or are in a fruitful condition. Old orchard trees will bear root-pruning of a severe kind when they happen to be growing in a strong deep soil, and are making more wood than is desirable, as they sometimes do in late districts, but, when they are removed altogether, the check they receive is very great, particularly if the trees have never been transplanted before; hence they require special treatment. In the winter of 1867, I had to re-arrange a large number of fruit trees. About forty of these were above thirty years of age, and had not been disturbed at the root during that period. They were in a rampant and unfruitful condition; the sub-soil under them was deep and moist, and into this the roots had penetrated. I began transferring the trees to their new quarters in November, without much hope of success, as I found it would be impossible to get any feeding roots away with them. They had penetrated far into the stiff loam, and within a radius of 5 feet from the stem scarcely a fibre was found—nothing but long bare roots that had to be chopped off at the above length, as following them to their extremities was simply out of the question. I, however, "lipped" the roots every 9 inches or so to induce fresh rootlets, and transplanted them with as much care as possible, though none could be moved with a ball of soil, as the roots had no holding power. By January they were all transplanted and mulched thickly as a protection against winter frost or summer drought, and but for this precaution I believe not one of the trees would have been alive at the present time. The year 1868 was excessively hot and dry, as most of us will remember. It was particularly so in this district, and aggravated in our particular case by an empty reservoir; the trees, therefore, received little or no watering, but depended on the mulching alone, which just enabled them to retain their vitality, and nothing more. With the exception of some half-dozen or so of the number, not a tree moved a bud perceptibly, and they remained leafless and bare from November, 1867, till the spring of 1869, thus actually losing a year of their existence. Their forlorn appearance attracted much attention, and many predicted the demise of the whole; still, though the bark on the branches shrank visibly, sections of the buds showed that vitality was still present, and we did not despair. The few trees that pushed out leaves, which they did feebly about June, all perished; the little foliage they made evidently exhausting the last remnant of vitality. The following year, however, all the trees were clothed luxuriantly with foliage, and for some years after many of them bore better crops than they had ever done before. Numbers of the same trees have since been again moved to an orchard, and are now growing vigorously. It is not often, I believe, that deciduous trees remain dormant a whole summer after moving, and eventually survive; but that they will do so is a fact beyond doubt, and that, as I have shown, under very adverse circumstances. Possibly few evergreens would survive under similar circumstances; but I can state that the Holly will. Some years ago I had to lift some large trees in June. Owing to the stony nature of the soil, only poor balls could be got with the roots; and, though they were well watered during the season, no leaves were put forth, nor did the buds appear to move. The second year after planting they made but the scantiest foliage, though they flowered freely along the leafless twigs, but bore no fruit. These trees are

now in excellent health. The importance of mulching thickly all newly-transplanted trees cannot be over-estimated. Stirring the soil during the summer has been recommended as being quite as beneficial as mulching; but this I cannot admit. Let anyone try the experiment of mulching a row of Raspberries, and stirring the soil only about another row, and note the result. They will assuredly find out that in one instance they have given their labour for nothing. We all know that to keep the ground well stirred among growing crops is a good practice in drouthy seasons, but where a mulching of short Grass can be applied, it is infinitely better, as plenty of gardeners know who have to contend with dry soils. Stirring the soil merely lessens evaporation from the surface of the ground, but mulching prevents it almost entirely. Under the thinnest layer of short litter or Grass, the surface of the soil will always be found sweet and moist. One marked effect of mulching is, that it coaxes the roots of both trees and vegetables to the surface, where they evidently derive considerable nourishment from the dressing, but this is never the case where stirring the soil is alone resorted to. For this reason, mulching is injurious to Potatoes, for it causes them to push their roots up to the surface, and to form their tubers there, where, as the mulching decays, they get greened, and are, of course, useless. It is well known, also, how a thick mulching encourages Vine roots to the surface of the border. Indeed, no amount of top-dressing and stirring will ever accomplish the same result so quickly and so successfully. In some places, where excessive neatness is required, mulching is objected to, and the hoe used instead, and with what result? I have seen such borders so cracked and rent during summer that you might have inserted a walking stick into the fissures in many places. This cracking is more apt to occur in fruit-tree borders than anywhere else, for, as a rule, they are not dug frequently like the vegetable quarters, and being hard and firm, get rent in all directions, like baked clay. These fissures present an increased surface to the action of the air, and evaporation goes on, both above and below ground, so to speak, and the result is red spider, and other evils, in an aggravated form.

J. S. W.

ON PRUNING THE REDWOOD.

(*TAXODIUM SEMPERVIRENS.*)

THE *Taxodium* or *Sequoia sempervirens*, as it is frequently called, was first discovered on the north-west coast of America by Mr. Menzies, in the year 1796, but was not introduced into cultivation in Great Britain till about the year 1843. Notwithstanding the length of time it has been in this country, it does not seem to have attained that place in public estimation which it justly deserves, probably owing to most of the young plants sent out from nursery establishments being cutting-made, and, therefore, not possessing at first that upright habit and general symmetrical appearance which ought to be peculiar to seedling plants. The *Taxodium* is perfectly hardy, and cutting-made plants, if properly attended to with regard to early and, for a time, an occasional pruning, will ultimately make excellent and well-formed trees. Care, however, must be taken of them till such time as they begin to assume a true upright habit. Many cutting-made plants often take on double heads; the weaker one must always be removed, and this can be done with safety at any time of its growth. This tree appears to stand any amount of cutting with impunity, and at all ages; indeed, the more pruning they receive the better for giving them a pyramidal shape. It is most essential for the after-growth of the leader that all the top side-shoots should be pointed; if not, they spread out rapidly, and are apt to disfigure a tree, particularly after the lower ones have been operated on. I have pruned them of all sizes, from 1 to 20 feet, and I never knew a specimen in the least degree injured by it. In many places the unpruned branches are often seen dead at the points during the spring months. It is a very beautiful evergreen tree, and well suited for lawn or avenue culture. After pruning it will be found that the twigs produced are very numerous, and usually assume a pendent and graceful appearance. Any amount of cuttings may be annually taken from one tree without disfiguring it; yet, notwithstanding

its free-growing propensity, it is but rarely seen in collections, and, when observed, appears a wide-spreading bush, and is anything but pleasing to look at. Comparatively few seeds, in a state fit for germination, seem to have come to this country, as I never had the good fortune to raise more than three or four, all other specimens under my care being cutting-made plants. In some establishments seedlings have been raised, but are often outgrown by plants struck from cuttings. The *Taxodium* succeeds well, both in high and low situations, and in all soils where free pruning has been tried; it also thrives in woods, where it is generally allowed to ramble about, and is often uncared for. A few plants were much injured here during the ever memorable winter of 1860-61; this, I consider, was owing to the weight of snow at that time bending down their unpruned branches, and exposing the ruptured vessels to the severe frost which at the time prevailed, the mercury falling to 5° below zero. The same kind of injury happened to many of the unpruned *Deodars* that winter, most of the branches being spreading, and the plants chiefly in a shrub-growing condition. I feel satisfied that many of the larger unpruned specimens, if well cut in during the months of September and October, and even later, will, on account of the pyramidal shape thus given them, be able to resist snow with more success than can possibly be expected of unpruned specimens. I have also pruned them during the spring months, and never experienced any bad results. The *Taxodium* is more frequently to be met with in England than in Scotland, and some now seen in sheltered situations have attained a considerable size; the generality of them, however, would be the better for a judicious pruning. It is a noble tree in its own country, and its timber, which is called Red Wood, is highly recommended for many purposes. The bark of the *Taxodium* is very like that of the *Wellingtonia gigantea*; it is of a thick brown cushion-looking substance. This peculiar bark is chiefly confined to the stem, as I have not observed it on the branches of any of the plants. Large seedling plants of *Taxodium*, although possessing rather short leading shoots, have, very generally, wide-spreading branches, giving the trees a somewhat hemispherical appearance. Some known to me, although of the same age as many cutting-made plants, which have been regularly branch-pointed from their infancy, are now scarcely two-thirds of their height; whereas some of the original seedlings, which have been regularly branch-pruned and pointed, have a totally different appearance, being tall and shapely; the sap, as may be expected, all going to support the stem and the new-made points of the pruned branches, instead of being wasted in forming the numerous free-growing side-shoots, which, by rights, ought to have been removed by early pruning, but are often neglected till they become wide-spreading. If cutting has to be resorted to they lose a good deal of the feeding properties which for years would have gone to make up the stem and pendent branches. The same remarks apply to several other Coniferous trees known to me. For my own part, I do not see any harm in the early working of a tree to make it useful for ornament, as well as for timber-making purposes.

JAMES McNAB.

Royal Botanic Garden, Edinburgh.

IS THE FRUIT CHANGED BY FOREIGN POLLEN?

PROF. ASA GRAY has an important article on this subject in that excellent monthly, the *American Agriculturist*. At this season, when Apples of a different variety from that of the tree that bore them, or combining two sorts in the same Apple, are brought in, it is natural that the discussion of the cause and origin of such freaks should revive, and run the customary round of the papers. You ask whether there is any new evidence that pollen may act immediately on the fruit of the fertilised flower so as to impart to it, as well as to the resulting embryo, its own specific character. In reply, I would say that the only recent contribution I know of, that really throws any more light upon this curious object, is an experiment by Maximowicz, a Russian botanist. He crossed two Lilies, which differ more in the form of their pods than in anything else (the common bulbiferous Lily and *Lilium davuricum*), and the wavy pod of the one developed directly into a pod of the shape of the other. This change of shape, so caused, seems to me even more extraordinary than the change of quality or texture, such as takes place in Squashes and Melons. I should think

that the fact of such action of pollen, wholly improbable, as it seemed to be, particularly to scientific men, is now pretty well established; and I find, on looking up the subject, that all this had been made out very long ago. This ought not to excite surprise, for our ancestors were quite as sharp-sighted as we are, and if this occurs now-a-days it must have occurred in former days as well. It is said that Theophrastus and Pliny allude to it, but I cannot look up that matter now. In the case of Apples, good old Peter Collinson, the correspondent of Franklin and John Bartram and Linnæus, brought some to the notice of the Royal Society in 1745, and there is a communication in the Philosophical Transactions of that year "concerning the effect which the farina of the blossoms of the different sorts of Apple trees had on the fruit of a neighbouring tree." Mr. Cook, the author of the communication, sent to Mr. Peter Collinson some Russetings, changed by the farina of a next neighbour, whose name he wanted still to know, but could only say that the Russeting had acquired his face and complexion. Mr. Collinson then produced several samples of the Apples, an untainted Russeting, a Russeting changed in complexion which grew among a great cluster of unaltered brethren, and some Apples of the other tree which had caused the change in the Russetings, and whose fruit had in return received a rough coat from the Russetings. It is curious to notice that, when this subject came up in England fifty years ago, illustrated by new cases, both in fruits and the coats of seeds (such as Pears), Mr. Knight, the prince of vegetable physiologists of his day, declared against the idea that the pollen had anything to do with it. As the upshot of his own observations in making "some thousand" experiments with pollen, in which he found no such changes, he remarked that he conceived himself qualified to decide that in the deviations of the fruits mentioned from their ordinary character, the operation of the pollen of another variety was not the disturbing cause. Soon after he took the same ground in respect to the coat of seeds. Nevertheless sufficient positive testimony has in both cases overborne the negative, but there is no indication that Knight was ever convinced by it. At the start he was prepossessed by another theory. He had already published an account of a branch of a yellow *Magnum Bonum Plum* that bore red fruit; but, though it did this only for a single season, bearing yellow Plums the next year, Knight still clung to the view he was committed to, i.e., that it was a case of "bud variation." There is something curious in the case of these Apples of two sorts. In a strongly marked case which I examined, a *Spitzenberg Apple* was russet on one side. The flower, of course, had five stigmas. If two or three of these were acted upon by foreign pollen, and the others by their own pollen, the strongly-marked difference of colouration should have divided the Apple unequally, one would think. But exactly one half was red and unchanged *Spitzenberg*, and the other russet. I believe this is often the case. It has lately been attempted to explain such Apples on the principle of reversion. This has been suggested as a more probable cause than the action of pollen. But that assumes that the Russet has *Spitzenberg* blood in it, or *vice versa*, which is gratuitous and most unlikely. The other explanation assumes nothing except what is known to take place in strictly parallel cases.

MINIATURE EVERGREEN TREES FOR SMALL GARDENS.

THE word "Evergreenery" may be hardly correct; but I can find no other which suits my purpose so well or will better convey an idea of what I here propose to describe. Arboretum is a higher sounding word, but not applicable, inasmuch as it means a collection of both deciduous as well as evergreen trees. There are many persons residing in the suburbs of our large cities and towns who own but a small plot of land, consequently, they seldom attempt much more in the way of ornamental gardening than setting out a few cheap bedding plants, or sow seeds of common annuals, on account, as they suppose, of lack of room to do anything better. It is to this class in particular that I recommend the miniature evergreens; while others, who have plenty of land and means, can use the larger kinds in addition. There was a time, not long ago, that to talk of a variety of evergreen trees and shrubs suggested extensive grounds; but, happily for those with limited means and gardens, those days are past. During the last decade or two our horticulturists have been picking up here and there in various parts of the world many rare species and varieties of dwarf evergreen trees and shrubs, until the most enterprising among them have extensive collections of this kind, with which a most elegant display of rich and varied foliage may be made even in a very small garden. The value of these miniature evergreens for small gardens can scarcely be over-estimated—not only on account of their permanent beauty, but their appropriateness for just such places seems to harmonise with the modern ideas of high art in gardening. The

fitness of things in general is not studied or thought of by many when trying to arrange the little garden-plot in front or elsewhere about their dwellings. Hence, the frequent planting of giant Pines and Spruces, by the dozen, within limits which would not suffice for one full-grown tree.

Arbor-vitæ.—Of the American *Arbor-vitæ* (*Thuja occidentalis*), there are several beautiful dwarf varieties, well suited to cultivation in small gardens. Booth's dwarf is a very neat compact bush, and of a lively, cheerful shade of green. Globosa is, as its name indicates, globular in form, and the foliage of a deep rich green colour. Plants in my ground, fifteen years old, are 3 feet in diameter, and about the same in height, and as perfect as though turned in a lathe. *Ericoides* is a very pretty variety, with very fine soft leaves, like a Heath; hence its name. Tom Thumb is one of the most curious as well as beautiful varieties ever raised from this species. It assumes a somewhat conical form and its leaves are soft and fine. It browns in winter unless shaded. The American Golden, is a new dwarf variety, with the ends of the branches of a clear bright golden colour. It is very hardy, and the rich golden colour of its leaves gives a pleasing contrast with the dark green of other kinds when planted in groups. *Argentea* or Silver-tipped *Arbor-vitæ*.—This is a very pretty variety, with the branches tipped with white.

Eastern Arbor-vitæ (*Biota orientalis*).—Of these there are also many beautiful varieties, and some of them are worthy of a place in the choicest collections. The Chinese Golden *Arbor-vitæ* is a very pretty variety, with fine foliage of a light yellowish-green. Another variety, known as the Elegant (*B. elegantissima*), has the branchlets tipped with golden-yellow. Melden's *Arbor-vitæ* (*B. Meldenensis*) has very fine soft leaves, similar to the Tom Thumb, but not quite as rich in colour. In winter, unless protected from the sun, the leaves change to a brown or reddish colour.

Junipers.—This genus furnishes us some very desirable dwarf species and varieties. The common Savin (*Juniperus sabina*), and the variegated-leaved variety, are two of the best for small gardens, as they are low, compact growing shrubs, with fine handsome foliage. The Trailing or Creeping Juniper (*J. squamata*), and Tamarisk-leaved (*J. sabinoides*) should always be planted at the extreme outer edge of a group, as they creep over the ground or form a very dense, low bush. They are very hardy, handsome, and desirable.

Taxus, or Yews.—Few plants have been more praised in prose and poetry than the Yew, and it deserves all that it has received. I will not try to discriminate between the dozen species and varieties cultivated by our nurserymen, because one can scarcely go amiss in selecting one or more, as all are suitable for small gardens, none growing very large during a lifetime; and should a specimen pass beyond prescribed limits, the pruning knife or shears may be freely used in bringing it back. There are golden and variegated-leaved varieties, in strong contrast with the dark green foliage of the parent species. The American Yew (*T. canadensis*), should never be omitted from the list of dwarf evergreens. Its deep green foliage and bright red berries in autumn are merits which place it high in the estimation of all lovers of beautiful plants.

Pines.—There are few of the true Pines which are admissible in a small garden, or in a group of evergreens, such as I have proposed. Mugho Pine (*Pinus Mugho*), from the mountains of Central Europe, may, however, be introduced as a dwarf, although an occasional specimen will assume the tree form, instead of remaining a dwarf shrub. A handsome specimen in my garden, fifteen years old, is only about 2 feet high and 4 in diameter. If a plant inclines to grow too tall, it may be kept down by cutting off the leading shoots. Another variety, called the Knee Pine, never grows on its native mountains (the Alps) more than 3 feet high.

Retinosporas.—We are indebted to Japan for these beautiful little evergreens. One of the most desirable among these is *R. aurea-plumosa*, the foliage of which is soft, fine, and of a brilliant golden colour, fully sustaining its name of "golden plume." I fear that few persons will be satisfied with a single plant of this in a group, for, when dotted here and there among the dark-coloured foliage of other kinds, they seem to give light and life to the picture, the strong and striking contrast adding much to the beauty and brilliancy of both.

Spruces.—Like the Pines, there are comparatively few Spruces sufficiently dwarf in habit for the city or village garden. But the few that are suitable are gems of their kind, and the most beautiful of all is a native of New York State, having been found upon the banks of the Hudson, a few years ago. It is known as the Weeping Hemlock, and may be considered to be among the evergreens what the Weeping Willow is among deciduous trees—i.e., the "Queen of Weepers." I regret, however, to add that it is still scarce and not yet in market, but probably will be very soon. There are also several varieties of the Spruce of a very dwarf habit. One known as the Pigmy resembles the Norway Spruce in everything except

size—a full-grown specimen scarcely exceeding 3 feet in height. Another variety, called Gregoryana, forms a neat little dense ball of green, 1 to 3 feet in diameter, and about the same in height. There are also many other varieties belonging to the same genera or species as those named above; but I have named enough to show that there is no lack of materials with which to satisfy those who may desire to make a fine display? [Thus writes Mr Fuller in the "Horticulturist" concerning evergreens for small gardens, but a great many more charming varieties and species might be added to the above, all of which are easily obtainable in nurseries.]

DALMATIAN AND OTHER INSECT POWDERS.

By HERMANN KALBRUNER.

CERTAIN species of *Pyrethrum* have obtained considerable reputation as insecticides; the *P. carneum* and *P. roseum* both growing wild, and frequently cultivated in the Caucasus, have both proved to be excellent in this respect. In 1846, a Tiflis merchant introduced the sale of these flowers into Vienna under the name of "Persian Insect Powder." Notwithstanding that *P. carneum* and *P. roseum* are indigenous in the Caucasus and Persia, they have been successfully cultivated in many localities in Europe and North America. The climate of Lower Austria suits them very well; they are found there as ornamental plants in gardens, and they grow in northerly cool places with especial luxuriance. I have had plants of *P. roseum* in my garden during several years, and they have supported the cold of winter without shelter. Under the name of Dalmatian Insect Powder, the flowers of *Pyrethrum cinerariæfolium*, a plant that grows wild in Dalmatia, have been used. Through a friend I have obtained some seeds from Dalmatia, from which I have been successful in raising plants in my garden, where they have lived through the winter in the open air. In order to test the effect of the different insect powders, I sprinkled some flies with the powders, and took the length of the time required to kill the flies as the measure of the value of the powders. When a house fly was placed in a small flask, sprinkled with four grains of insect powder, if the powder was very powerful, there was considerable stupor at the end of one minute, followed by death of the fly after two or three minutes. The commercial insect powders behaved differently in this respect, some of them corresponding completely to the above standard, whilst others, although they quickly stupefied flies treated as above, required fifteen to thirty minutes to kill them. The druggists in Vienna purchase the whole flowers, yielded by the uncultivated Dalmatian *Pyrethrum cinerariæfolium*, and the powder they supply is a very energetic preparation. It is noteworthy that both these entire flowers and the powders prepared from them, after being kept six years, do not suffer any particular loss of activity. I have found the powder of the flowers of *P. cinerariæfolium* very active. *P. roseum* appeared to be slower in its action, which I ascribe to the circumstance that the single flowers are much more powerful than the double flowers, which appear to have little activity. The double flowers occur in *P. roseum* in much larger proportions than in *P. cinerariæfolium*; and to this fact I consider the greater activity of the latter due. The fresh (undried) flowers of both these *Pyrethrum*s will kill flies, but very slowly. The plant itself, powdered, appeared to be quite inactive. In a similar manner I have tested the powdered flowers of several Austrian Compositæ, and have found the following to be quite inactive in this respect:—*Chrysanthemum leucanthemum*, *C. coronarium*, *Anthemis arvensis*, *A. Cotula*, *A. tinctoria*, *A. nobilis*, and *Inula pulicaria*. The flowers of *Tanacetum vulgare* and *Pyrethrum corymbosum* appeared to have a very slight stupefying effect. Of all the Austrian indigenous Composites tried, only the powdered flowers of *Pyrethrum parthenium* and *P. inodorum* exercised a stupefying influence upon flies, and that only after the flies had been dusted from one to two hours; their value, therefore, as insecticides, is very slight. In a scientific aspect, it is, however, interesting to notice that up to the present time the action obnoxious to insects has only been observed in the genus *Pyrethrum*, whilst from other composites approaching very nearly to that genus the property is absent. Some years since, the *Journal de Pharmacie d'Anvers* contained an article, asserting that the insecticidal action of Persian insect powder was due to powdered flowers of *Anthemis Cotula*. I have, however, found the flowers of this species quite inactive, since flies which had been dusted with it were, after four hours, still able to fly away readily. I, therefore, conjecture that a species of *Pyrethrum* was mistaken for *A. Cotula*. The cultivation of *Pyrethrum roseum* and *P. carneum* has already been attempted in various places in Austria. The author's experiment with *P. cinerariæfolium* yielded the flowers at a slight profit. But, as very active flowers can be obtained from Eastern Asia and Dalmatia at a moderate price, he does not think that home cultivation would be remunerative.

NOTES OF THE WEEK.

— WE saw the other day some twelve hundred healthy plants of Venus's Fly trap (*Dionæa muscipula*) in Messrs. Rollisson's nursery, at Tooting. They had recently been imported from the neighbourhood of Wilmington, North Carolina, and are just now making a vigorous start. This *Dionæa* being one of the reputed insectivorous plants, to which so much attention has lately been directed, possesses an interest apart from its singular structure and fresh green colour.

— IN the *New Quarterly* there is an article on English flower gardens, which is interesting in parts; but, when the writer comes to suggestions for the future, and enumeration of materials, passages like the following do not betray acquaintance with the subject:—"Next comes that fine group of shrubs the Hibiscus, from Syria, from Africa, and from Japan, with the great bright red, purple, and yellow flowers, and leaves so variously and beautifully pinnated, that the Japanese make them a constant 'motive' of design in their best art work."

— THE index and title page for the volume ending 1874, together with a portrait of Mr. Marnock, will be published with next week's number of THE GARDEN.

— MR. CROUCHER writes to us to say that *Aloe fruticosa*, and the Abyssinian, and tree Aloes are now finely in flower in Mr. Peacock's collection of Succulents at Hammersmith.

— IT is reported that the King of the Belgians is about to erect a vast circular conservatory in his park at Laeken, from designs prepared by M. Balat.

— COCOANUTS were highly esteemed by the Mogul Emperors for goblets, for which purpose they were beautifully polished, fitted with gold rims, and adorned with precious stones. It was supposed that poison would lose its fatal properties when placed in such vessels.

— THE January number of the *Florist* contains coloured representations of Rose St. George, a fine full deep crimson variety, the smooth incurved petals being shaded behind with soft lilac-purple; and Welbeck seedling Nectarine, a kind about the size of the Elruge or Balgowan, but of a rich crimson colour, sparingly dotted with yellow. It is said to be of excellent flavour, and appears to be a welcome addition to this class of fruits.

— DR. RICHARDSON, of the University of Louisiana, writing to us from New Orleans, speaks of the great riches and beauty of the vegetation near the city of Mexico, and sends us an interesting account of the ascent of Popocatepetl, the great mountain, made by a party of which he was one. He doubts if, in any other part of the world there exists so great a variety of plants within so small an area of country as in the vicinity of Cordova and Orizaba. From the alpine to the strictly tropical is not half a day's journey. He adds, that from New Orleans to the city of Mexico is but a few day's journey—by sea to Vera Cruz, thence by rail.

— MR. QUILTER proposes to hold a series of annual flower shows in the Lower Grounds, at Aston, for the benefit of public institutions in Birmingham. He will take upon himself the cost and risk of such exhibitions, and then share the profits with the selected institutions, after the expenses are paid. The exhibition of this year will be for the benefit of the Birmingham Institute, that next year for the Sanatorium, that of 1877 for the School of Art—leave being reserved for the Queen's Hospital to take 1878. In return for his offer Mr. Quilter stipulates for the formation of a general committee from the committees of these institutions, with the addition of other gentlemen who may be disposed to assist. The first exhibition will be held on Thursday, July 1st, and on the following Friday, Saturday, and Monday for the benefit of the Midland Institute Building Fund.

— THE January number of the *Botanical Magazine*, contains coloured figures of the following new or rare plants:—The Horned Gum tree (*Eucalyptus cornuta*) of Australia, which in cultivation at Kew, in the great temperate-house, forms a small tree 9 to 10 feet high, and flowers every year from the old wood. The flowers are borne in globose heads from 4 to 6 inches in diameter, the extinguisher-shaped covering of the yellow anthers being of a vivid scarlet colour.—*Crocus byzantinus*, a native of Transylvania, and a favourite in many old-fashioned gardens, has been cultivated in this country for the last two or three centuries. Its showy triangular flowers are of a deep purple-lilac colour.—*Jamesia americana*, a very pretty white-flowered plant nearly related to the Hydrangeas and the Saxafrages. Its dull, green, hairy leaves are oblong and serrate, the flowers being borne in terminal panicles.—*Blumenbachia chuquitensis*, a densely hairy plant nearly related to the pungent Loasas, having lacinate deep-green foliage of erect growth and brilliant flowers, scarlet without, and golden-yellow within.—*Odontoglossum maxillare*, a showy species, from Mexico, said to be nearly related to *O. Cervantesii*, but it has far more affinity with *O. cordatum* and *O. maculatum*,

from which it is easily distinguishable by its white flowers. The segments are blotched with purple at the base, the lip blotched with orange-yellow.

— A NEW botanical annual, intended chiefly as a record of progress, has been started under the editorship of Dr. L. Just, of Carlsruhe. It is entitled *Botanischer Jahresbericht*.

— THE presentation of the Cutler testimonial, consisting of a silver tea and coffee service, &c., subscribed for by the members of the Gardeners' Royal Benevolent Institution, will take place on Thursday next, the 14th inst., after the annual general meeting of that charity, which takes place on that day.

— IT has recently been shown by M. Baillon that the leaves of plants are capable of absorbing water. He has been experimenting by sowing Peas in a box of such a construction that the plants can be immersed in water without the roots or the soil in which they are growing becoming damp. He has kept Peas alive for two months without giving the roots any water whatever, the soil being virtually quite dry.

— THE fields of Sugar-beet near Sacramento, California, are reported to have been saved a short time back from destruction by vast armies of caterpillars through the labours of a flock of 3,000 turkeys. The struggle was evenly balanced for a time, and then success wavered, first one side gained, and then the other; finally the turkeys triumphed, with the loss of one over-gorged victim, from whose crop alone were taken 1,500 caterpillars.

— MR. ATKINS, of Painswick, has sent us specimens of *Cyclamen Atkinsii*, which have withstood 25° of frost in the open air without injury. The thick tufted leathery foliage, prettily marbled with silvery-grey and the short petalled white flowers, blotched at the mouth of the tube with dark purplish-crimson, render this one of the most interesting of Cyclamens, and one which, as a winter-blooming plant for sheltered nooks in the rockery or in the wild garden, has few equals.

— SIR THOMAS D. ACLAND, BART., M.P., was summoned before the magistrates at Exeter the other day, for neglecting to have the hedges trimmed and trees lopped in various parts of his estate. In defence the hon. baronet said his father was fond of preserving the picturesque features of the Devonshire lanes, and out of respect to his memory the trees and brushwood had been left in their natural growth. An order was made by the magistrates for the removal of the cause of complaint.

— MR. W. PHILLIPS, of Shrewsbury, proposes to publish, under the title of "*Elvellacei Britannici*," dried specimens of the larger Ascomycetous Fungi. To persons forming collections of our indigenous Fungi, Mr. Phillips's fasciculi will be useful, since similar collections have hitherto principally comprised only the Hymenomycetes. Mr. Phillips will be assisted by various well-known mycologists, and he proposes to issue a very limited number of copies at 12s. each fasciculus of fifty species.

— M. GAILLARD has lately exhibited, according to the *Revue Horticole*, some very extraordinary Gourds, of various forms and colours, which, although attached to each other, are of different species. This has been accomplished by grafting the fruit of one kind upon that of another, when it is found that perfect adhesion takes place, and that the growth of each fruit continues unretarded. One example given is that of a green Spanish Gourd, upon the side of which another variety has been grafted. Another is that of a yellow Apple-shaped Gourd, into which was inserted the stalk of a green Pear-shaped one, a large section of which was cut off and replaced by a corresponding slice of a white-fruited Gourd; in all cases a perfect union has been effected.

— IN a lecture delivered a few days ago at the London Institution, Sir John Lubbock said:—"The observations commenced by Sprengel and recommenced by Darwin seemed to have given to flowers an additional interest, and had shown that insects, and especially bees, had an importance previously unsuspected. To them we owed the beauties of our gardens and the sweetness of our fields. To them flowers were indebted for their scent and colour, indeed their very existence in its present form. Not only had the brilliant colours, the sweet smell, and the honey of flowers been gradually developed by the unconscious agency of insects, but the very arrangements of the colours, the circular bands, and the radiating lines, the form, size, and position of the petals, the arrangement of the stamens and pistil—all had reference to the visits of insects, and were disposed in such a manner as to ensure the great object which these visits were destined to effect." Probably few will go so far as this with Sir John—even of those who see how animals and plants may influence each other in the struggle for life. Sir John's illustrated essay on this subject has been published by Messrs. Macmillan this week.

THE FLOWER GARDEN.

CULTURE OF THE GLADIOLUS.

THOSE who wish to have a fine display of Gladioli next summer must now begin to prepare beds and clumps for their reception. Bulbs intended for planting should be obtained now, when they are well ripened, plump, and sound. The best time for planting is in March, commencing quite early in the month if the weather is at all favourable. In order to secure an effective display and, at the same time, afford the plants an opportunity of fully developing the beauty of their flowers, they should be planted in beds, formed in rows not less than 18 inches apart, with a clear space of a foot between each bulb in the line. Some cultivators have recommended pitting the bulbs preparatory to planting them out, and growing them on for a time before transplanting them to the open ground; but experience has proved that no advantage is derived from such a practice. Some have recommended planting as early as January or February, but it is best done in March, for that is early enough in the year to give the plants a beneficial start, while the risks of rotting or being otherwise injured through heavy rains in the earlier months are considerably lessened. If a few late flowers are required, the planting of some of the bulbs may be deferred till the middle of April, in order to ensure a succession of bloom. The preparation of the soil is an important point.

A deep loam suits the Gladiolus best, and the bed in which the roots are to be planted should be previously well trenched to the depth of 18 inches, digging in, at the same time, a good dressing of well-decomposed manure. Thoroughly rotten vegetable refuse and wood ashes, as well as some crushed bones, greatly assist in the development of the plants. As soon as the growth begins to appear through the soil, a thin dressing of fairly dry rotten manure may be put on the surface of the beds, a dressing from which they will derive great advantage, increasing the quantity as the plants mature their growth and the height of summer is reached. The course of treatment during the summer includes the keeping of the beds clear of weeds, and giving occasional stirrings to the surface. When the flower-stems reach a foot in height, each should be carefully tied to a stake to support it, and

preserve it from harm from wind, which is very apt, unless the flower-stalks are properly supported, to twist them off close to the bulbs. In dry weather frequent sprinklings overhead and good surface waterings will be necessary, though the dressing of manure will do much to keep the bed moist and cool. In tying out the flower-stems to stakes and supports, be careful not to tie them too tightly; sufficient space should be allowed to admit of an unfettered upward growth. Continue to tie as they advance in height, or the bed will have an irregular appearance. The taking up and storing of the bulbs is a matter of considerable importance, and the removal of the roots from the beds should not be deferred till the stalks die down completely. It is best to lift them when the leaves turn yellow, and cut away the decaying flower-stems to within 6 inches of the bulbs, and the latter should then be placed in a cool airy place to dry. They should be put in drawers, baskets, or bags when ready, and be laid in a moderately cool and dry place, each variety being kept separately and distinct, and correctly named. Frost must be guarded against, for a severe one will cause many of the bulbs to rot. In such a place the roots can remain till planting time comes round again, examining them occasionally to see that no harm results from damp. When the bulbs are lifted it will be found that some of them have formed a few smaller bulb offsets, while others will have produced round the base a larger number of roots of small size, denominated "spawn." In the former case the offsets may be allowed to adhere to the bulbs till thoroughly dry or wanted for planting; in the

latter case the spawn should be removed when the bulbs become dry. If it is desired to save the spawn of choice varieties, it should be planted out closely together in a prepared bed in the spring; and, if some attention be given it during the summer months, such as keeping the plantation free from weeds, watering, &c., a good many of the spawn bulbs will grow sufficiently strong to flower the second year. Most cultivators of the Gladiolus like to try their hands at raising seedlings. It is not a difficult matter, and seed is freely borne and ripened. Seed saved from the best varieties may be sown early in April, either in pans or shallow boxes, or in prepared soil of a fine and rich character in the open ground. When the plants begin to show themselves, they should be encouraged with a little weak manure-water, occasionally administered. When large enough to be transplanted, they should be planted out in beds, about 4 inches apart each way, in some good light soil, and encouraged to make all the growth possible during the season. A large number of the seedlings will flower the second or third year from the time of raising. As to kinds, the following are fine in quality and distinct in character—viz., Ada, salmon-red, white throat; Beauty of England, white, with purple throat; Coronet, bright red, the throat flamed with white; Distinction, orange-rose, purple throat; Grandeur, blush, flaked with carmine, extra fine; Julia, pink, suffused towards the edges with carmine, and very purple flakes, very fine; Lord Derby, crimson, very fine; Medina, flesh, flaked with violet;

Miss Warren, cerise, with white throat, very beautiful; Modesta, crimson, shaded with maroon, very fine; Mr. Greenville, violet-rose, striped with lilac, very fine and striking; Mrs. Stuckey, clear rose, tinted with violet, and flaked with purple, beautiful; Pluto, orange-scarlet, yellow throat, very fine; Opalia, orange-rose, the yellow throat flaked with violet-rose, very fine; Orphée, rose, flamed with carmine; Plauda, crimson, the white throat blotched with violet; Prince Arthur, white, flaked with lilac-purple, very fine; Remarkable, lilac, flaked and mottled with purple, very distinct; Robert Fortune, carmine, flamed with crimson in the throat; Sentinel, purplish-rose, flaked with lake; Sybil, canary-orange, throat striped violet; Titus, lilac, flaked with violet; Virginalis, pure white, bordered and flamed with rose; and Volano, dark rose, flaked with a darker hue, pale throat. Messrs. Kelway and Mr. Sampson, in this country, and

M. Souchet in France, have made Gladiolus culture a speciality, and many fine kinds have been raised by them. Prominent among French varieties of recent date may be named the following, all of which are distinct and fine, viz.:—Ambrose Verschaffelt, Asmodée, Belladonna, Humboldt, Delicatissima, Eva, Horace Vernet, Jupiter, L'Unique, Madame Desportes, Maréchal Vaillant, Margarita, Mary Stuart, Michel Ange, Minerva, Mozart, Octavia, Ondine, Ossian, Blanche, Rosa Bonheur, Sappho, Semiramis, Sir John Franklin, Sultana, Talisman, Variabilis, Venus, and Zelinda. Quo.

Yucca Treculeana.

YUCCA TRECULEANA.

THIS species, represented in the accompanying illustration, is one of the most remarkable of its kind as regards general appearance and the size to which its leaves attain. The stem, which is about 10 inches in diameter, is furnished all round with leaves about 3 feet 6 inches long, straight, thick, deeply fluted, and tapering off to a sharp point. They are dentated at the edges, which are of a reddish-brown colour. The flower stem, which rises upwards of a yard, consists of a mass of branchlets about 18 inches in length, bearing multitudes of cream-coloured flowers, shining as if glazed. This variety of Yucca originally came from Texas, whence it was brought by Mr. Trecul about the year 1850, and it grows so luxuriantly that it is not rare to see specimens of it measuring over 6 feet in diameter.

THE FRUIT GARDEN.

GRAPE VINES.

(SECOND YEAR'S TREATMENT.)

At this stage it will be necessary to say a few words on the subject of temperature. On this point, a few noteworthy fruit-growers allow considerable latitude, preferring rather to be guided by circumstances and weather conditions, than by hard and fast rules. With the Vine, however, in the earlier stages of forcing, unnaturally, not to say injuriously, high night temperatures have been the rule hitherto, though a certain reaction appears to be setting in in this respect. If we compare the night temperatures generally recommended for the Vine, from the starting period till the setting of the fruit, it will be found, that they far exceed the average night temperature during the same period of growth in those countries most favourable to the Vine; and what makes the matter worse, these excessively high temperatures are given under circumstances which only increase their power of mischief; as, for instance, when the Vine is forced in a Vinery under our cloudy skies, and during the long dark nights of winter and spring. When the Vine is growing, the night temperature must, of course, bear some proportion to that of the day; but night is the period of rest to plants, which rest means a suspension of those exciting influences—heat and light—under which, combined, perfect growth can only take place. Physiologists tell us, and experience proves, that though the shoots will lengthen nearly as much by night as by day, under a disproportionately high temperature, no new material is formed. What takes place is, in the words of Dr. Lindley, “simply an extension of the tissue formed during the day,” and the consequences are weak wood and foliage, that can ill resist the parching effects of hot-water pipes, a feeble constitution, insect attacks, and other evils, in the way of scorching &c., that the gardener is only too familiar with. Bearing these facts in mind, I have deviated considerably from the beaten tract, and have, when hard firing would have been necessary to sustain the desired temperature, subjected all sorts of Vines, and notably Muscats, at all stages, between the starting of the Vines and the setting of the fruit, to a night temperature, that would at one time have been considered so low as to be fatal to the setting process, and injurious to the Vines generally; but with results so actually favourable to the health of the Vines, and the setting of the berries, that I adhere to the practice in all cases, and have no hesitation in recommending it to others, as being probably most in accordance with Nature, safe, and, without doubt, the most economical as regards fuel. I have repeatedly subjected Muscats to a temperature of from 50° to 55° at night, for a fortnight at a time, according to the weather, from the time the flowers first opened till all the berries were set, damping the house as usual, and occasionally syringing the Vines and bunches in the afternoon, and the berries have invariably set as thick as Hamburgs generally do. I put the success down simply to the sturdy vigour acquired by the shoots and bunches, through the absence of high and stimulating night temperatures, for I depart but very little from the usual day temperature. One fact, which I regard as conclusive evidence that a low, or resting night temperature is favourable to the fertilisation of the berries, is the number of stones or seeds they contain. Under high and dry setting temperatures I have never found the berries of Muscats to contain more than two or three seeds, but since I adopted low temperatures I find the average number is about four, and not unfrequently they contain five. In practice, therefore, instead of adopting a night temperature, which, in the usual acceptation of the term, means reaching the minimum about dusk, and sustaining it by fire-heat, if necessary, till the following morning, the rule should be to reckon the maximum at noon, and the minimum at sunrise, as I pointed out in your last issue. Further particulars will be given when we proceed to the details of the second year's treatment, and the directions given under this head will also be applicable to subsequent years. The beginning of March is soon enough to start the Vines the second year. Before this the Vinery should be thoroughly washed with soap and water. The Vines also may be washed, though I never found painting and

dressings exert the least influence in checking spider and other insects, if the treatment generally was such as to encourage these vermin; consequently, I never take the trouble of scraping and painting the canes before starting. The Vines may be unslung and laid horizontally along the wires, in order to induce the regular breaking of the buds, but, with well-ripened Vines, started about the natural season, this practice is not absolutely necessary. The inside border should first receive a good soaking with water at a temperature of 75° or 80°, and afterwards be covered with a bed of leaves (if these can be procured), laying them in a ridge along the middle of the border, or between the rows of Vines; but taking care that they are not packed against the stems of the Vines, as it causes the latter to emit roots at the wrong place. For similar reasons the heaps should be turned at least once a month, as the roots are sure to take possession of the leaves if this be not done, and will have to be sacrificed when the leaves are removed in autumn. For the first fortnight no fire-heat will be required at night, unless the weather is severe; but on cold dull days it will be necessary to apply a little heat in order to raise the temperature to 55° or 60°, and in bright days it may be allowed to go up to 70° or 75°, always observing the directions given under the head of airing and damping, &c. The object should always be to apply heat with light; if the temperature falls before sunrise to 40°, or even to 35°, no damage whatever need be apprehended. As to temperature generally, it will suffice to state here that a rise of about 2° per week should be allowed, until the night temperature reaches 70° or 75°, and the day temperature 85° or 90°, according to the varieties grown. This is allowing the maximum to be reached in about three months from the time of starting. I give this scale simply as a general guide, which might be strictly adhered to if the weather out of doors advanced steadily at the same rate; but this cannot be depended on, and of course a considerable abatement must be made on dull days and cold nights, when very hot pipes would be required to sustain the temperature at the proper figure. On such occasions an abatement of 5°, 7°, or 10° on the above scale will never do harm, but good, especially at nights, always making up for any loss in this way by going about as much above the scale in fine days, by shutting up early, and also by firing, if necessary, with sunshine. It will be found in practice that this compensatory system is the safest, and in every way the best, in this fickle climate of ours, with the Vine when grown under glass. Having given these directions, it will only be necessary for me now to speak of the training of the Vines and thinning of the fruit. As soon as the Vines have fairly burst their buds, they must be moved from their horizontal position, and tied to the wires in their proper places. The treatment of the permanent plants consist in carrying the leading shoots forward to the top of the house and there stopping them, as in the previous year; the side laterals must also be pinched as before directed, for these will push strongly when the leader is stopped. Those shoots which break from the last year's wood, below the base of the leader, should be stopped at the fourth or fifth joint; any bunches they show must be removed, and when they will bend without breaking, they may be tied to the wires. As to the supernumeraries: when it is seen which buds are the strongest, and which show the most promising bunches, they should be thinned by rubbing off the weakest with the finger and thumb, so as to have the shoots about 9 inches apart on each side, and they should be stopped one or two joints before the bunch, and tied to the wires when they will bear it; care must be taken that they do not come in contact with the glass before this can be done. After this period the treatment consists in pinching the laterals regularly at every joint, and thinning out the wood occasionally as it gets crowded, so as to expose every leaf to a good light. The front row of supernumeraries will have no room to extend themselves at the point, but the back row may be allowed to make a few feet of young wood in order to increase the bearing area the following year. When the Vines come into flower, extra care will be required in giving air so as to prevent sudden gusts of cold air, or great fluctuation of temperature during the day; otherwise no different treatment as regards temperature, syringing, or damping, is

required; the Vinery at this stage, as at other times, should be allowed to get dry during the greater part of the day, except when the usual sprinkling of the paths and borders, &c., takes place to prevent aridity, as before recommended. As soon as the berries are fairly set the number of bunches should be reduced to from four to six on each Vine, according to the size of the bunches and the vigour of the Vines, but with an eye to their even distribution over each plant.

Thinning the Berries.

All the bunches will not set simultaneously; but thinning must commence with the earliest set bunches before the berries are much larger than pin-heads (except in the case of Muscats and shy-setting varieties, which must be left until it is seen which berries are taking the lead), and it will be found by far the least laborious practice to follow it up as fast as the bunches set. It is difficult to give written instructions as to thinning, as much depends upon varieties and the vigour of the Vines, &c.; but, as a rule, Hamburgs and Muscats, and all the large-berried kinds, will require from three-quarters of an inch to one inch of space, cubic measure, to each berry, and other varieties a little less. As a rule, the inexperienced operator errs by leaving far too many berries; a bunch of Black Hamburgs, for instance, when thinned properly, looks to be simply decimated to the non-professional eye; but all good Grape growers use the scissors freely, and cut out from one-half to three-fourths of the berries in well-set bunches. The operator should begin with a pair of clean, sharp, and easy-working scissors, and with a smooth peg or stem of a Vine-leaf in the left hand and the scissors in the right, he should begin at the bottom of the bunch and work up to the top, easing the shoulders with the peg while he works the scissors, and, as far as possible, doing the thinning by cutting out the small berries and leaving the big ones, always remembering that most room is made by cutting out the inner berries. Cutting off the berries at the extremities of the shoulders only reduces the size of the bunch without easing the others to any extent. After thinning, the treatment is only a question of temperature, airing, damping, pinching, &c., as before directed. The temperature should not be lowered till the Grapes are ripe; but, after that, it may be gradually reduced with increased ventilation and a much drier atmosphere, until fire-heat is entirely discontinued, except when it may be necessary to expel damp for the sake of the fruit. J. S. W.

(To be continued.)

RIPENING OF THE WOOD IN PEACHES AND NECTARINES.

In its natural state the Peach tree grows as a standard, and we can conceive that under the bright sky of Persia—its native country—every twig or leaf must have the full benefit of the light and air, and that the wood and buds must consequently be thoroughly matured. Perfect maturation is all that the most favourable climatic conditions can accomplish, and is in fact the whole secret of success. In this country the ripening of the wood is the chief difficulty we have to contend with; this important end secured, good crops of fruit annually should be a certainty, were over-cropping avoided, and ordinary precautions taken against accidents during the flowering season. Half the failures that occur may safely be put down to ill-conditioned immature growth, and all beginners in Peach culture should realise this fact at the outset, and get to understand what maturity means, and what a well-ripened Peach-shoot is like. In our insular climate, the thorough maturation of the wood is not always easily secured, even with the assistance of glass and hot-water pipes. With Peaches that are forced early there should be no difficulty in this respect, one would think; but often enough these fail from the same cause, brought about by bad training and mismanagement. A well-drained border, a strong firm soil, enriched as often as needful, heat, light, and air, are the essentials needed to reduce the crude juices of the plant to the hardened tissue and plump buds which alone can produce fruit of good quality. There is a reluctance among many to manure Peach borders; but manure will do no harm where the roots have to push their way through a hard medium, and where heat and light are brought to bear upon the wood and foliage in proportionate intensity. The most remarkable Peaches for size and quality I ever saw were produced by trees that were annually highly manured by mulching or otherwise, and where strong wood, well ripened, with evenly distributed vigour, was aimed at and

secured by high temperature and thin training. One of the most prevalent mistakes in Peach culture on walls and trellises is thick training. It is the rule, almost without exception, to lay the wood in so thickly during the growing season that the trellis is completely thatched, and quite impervious to the light. The leaves on the upper side of the branches only get the full benefit of the light, but those on the under side are in the dark, and they are so crowded together between the shoots that they actually become to a certain extent blanched. Now, what result, other than failure, partial or complete, can be expected from such treatment? Trees trained to a trellis inside a lean-to structure are already disadvantageously placed as regards exposure to the light and air, and the evil can only be compensated for by careful training and ventilation. Far too much wood is, as a rule, laid on during summer, through nervous anxiety to provide an ample supply of heavy wood for the following season—the operator calculating upon reducing the quantity at the winter pruning, should it be necessary; and in this way future success is sacrificed for a purely imaginary gain in the meantime. Crowding produces two or three indifferently matured spindly shoots for one that is thoroughly so. The shoots should be wide enough apart, when in full foliage, to permit a free play of light and air among the leaves. Though the shoots may appear to be thinly distributed, the chances of a healthy blossom, a thick-set and a heavy crop of fruit, are increased tenfold. A healthy Peach shoot, when in leaf, measures 1 foot or more across—i. e., the leaves are about 2 inches diameter, 6 or 7 inches long, and are borne about 1 inch apart on the shoots. If growths of such luxuriance are tied into a trellis, which exposes only one side to the light, about 2 inches apart—as is commonly done—is it possible for each leaf, upon the healthy development of which everything depends, to have more than a mere modicum of justice? I leave Peach-growers to study this question. Here I give each summer shoot 6 inches to itself, though I admit a foot would not be too much. At the same time I untie all the branches, great and small, in winter, lay them out easily on the trellis, in which position the shoots all stand up towards the glass, and are swayed to and fro with each puff of air; and they are left in this condition till the trees are disbudded the last time and the fruit stoned. They are then tied to the trellis in the usual way; but I never aim at geometrical precision in training—straight-lacing is always to be condemned. Lay the shoots in easily, never tie them too near the point, and always take care that the growing point is well up and exposed to the light. During the growing season, whenever you think the shoots are getting too crowded, cut them out without fear. Always see that the sun shines through between the branches upon the floor beneath. This is a pretty safe rule. Trees trained in this way should require little or no pruning in winter; that is, presuming the young shoots are left entire, and not tortured at all. Not of less importance to their training, as an aid to maturation, is ventilation. Providing the proper temperature can be maintained, and avoiding cold draughts, the ventilation can never be too abundant. Too much moisture in the air is prejudicial, more particularly with a high night temperature. Plenty of water at the roots is essential; and when this is secured, damping and syringing is quite unnecessary, unless it be practised with a view to keep down insects, or to counteract the scorching influence of very hot pipes. When hard firing is not necessary the air is always moist enough for Peaches. It is a dry sunny atmosphere which produces that dark leathery foliage, and jointed brown-coloured wood with plump buds, which alone indicate perfect ripening. J. S.

GRAFTED ORCHARDS.

GRAFTED orchards, apparently, do not pay, if we may judge from the following extracts from a letter in the *Mirror and Farmer*:—My orchard is a good one; the trees are thrifty and bear well. I set them out and grafted them myself nearly twenty years ago, and for eighteen years I have tended, cultivated, and manured them; but were I going to live my life over again I would never try to raise another large orchard of grafted fruit. Why? Because it does not pay. My orchard will yield a hundred barrels of Baldwins, which, at 8s. a barrel, will bring in £40, and this, you may imagine, is all profit. But, when you come to look into the matter, you will find that that is not the case. For the expenses of picking, sorting, barrelling, and drawing come to £17 10s., and if you divide the remainder by two—for the trees only bear every other year—you have about £11 5s. as the income of the best field I have, which had to be cultivated ten years, and which now has to be manured to raise a good crop of Grass. But the kind of orcharding that does pay is this: On a hill, not far from my field, is a number of old scraggy Apple trees loaded with Apples about as large as pullets' eggs, not one of which is fit to be eaten raw or cooked; yet more money is made out of them than out of my Baldwins, which, had I

my wish, I would change into the old-fashioned trees yielding fruit only fit to be made into cider. Cider is the best paying crop I have. There is no particular secret about making cider, and yet its quality depends very much upon how it is made and what it is made out of. In the first place you cannot make first-rate cider out of windfall grafts. I do not know why, but so it is. If I were going to make a premium barrel of cider I would take sound fruit and have, if convenient, part of it sweet, then grind it in a mill that crushes instead of cuts the Apples; let the pomace stand in the trough twenty-four hours, and "cheese" it with clean Rye straw. When it comes to barrelling the main thing is to get a sweet clean barrel, that is, if you want pure cider to drink during the winter or spring; but if you want a drink for next summer or next year which is as stout as old rum, you can get it by putting in a pound of sugar to every gallon of cider.

Grapes Travelling without Packing Material.—Mr. Thomson has sent many tons of Grapes from Clovenfords to London without any packing between the bunches, and, I have been told in Covent Garden, that such packages arrived in as fine condition as if the fruit had never been packed. The baskets used for this purpose hold about 16 lb. of Grapes. Previous to placing the fruit in them, a thin layer of paper shavings is laid over the bottom and all around the edges of the basket, after which, filling is begun at one end, the bunches being put into position closely, and gently pressed against each other until the basket is full; on the slightest concussion the berries work themselves into the vacant spaces, and the whole becomes, as it were, one huge bunch. Besides the safety to the fruit, this system has other advantages—all expensive packing material is saved, and a considerably greater quantity of fruit can be got into a given space than when packing is employed; something, however, should always be placed between the basket and the fruit. Large quantities are easier packed thus than small samples; but both may be sent in this way, at any time, and any kind will withstand such carriage. Cotton, or any other kind of wadding, should never be placed in contact with Grapes, unless they have previously been carefully wrapped up in a clean sheet of tissue paper.—M.

St. Michael Pine-apples.—These were but scantily imported when I used to visit Covent Garden; the principal supplies of this fine fruit then came from the West Indies, and, in my opinion, were greatly inferior to home-grown produce. This fact, I imagine, has led many to suppose that the qualities of the St. Michael Pines have been overrated; but owing to the way in which they are cultivated there, and the careful manner in which they are imported, I can easily believe that they are good in quality. There is one statement made in reference to them, however, which I cannot clearly understand, and that is their being great favourites with dealers on account of their being invariably sounder at the core than fruit grown at home. St. Michael Pines are grown quite in a natural way, and these being sound at the core indicates that any decay found in home-grown fruit must be the result of artificial appliances, and what I would like to have fully explained is, how black-heartedness occurs. I have previously stated that I am convinced that any discolouration at the heart is the direct result of over-watering and of giving water after the fruit had begun to colour. This opinion was, however, contradicted. British fruit-growers, and young Pine-growers in particular, will, however, now be somewhat galled to know that foreign Pines are sought after in the market on account of their superiority over their own productions. Such being the case, I trust that those who are so ready to confute well-grounded propositions will no longer keep the "true cause" of this black-heartedness a secret, but will publicly explain the whole matter. It is not just to suppose that this rottenness is confined to fruit furnished by market growers only.—J. MUIR.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Raisin de Calabria and other Late Grapes.—Mr. Thomson states, in the *Gardener*, that he has at present the Raisin de Calabria more of a golden colour than any Muscat or other Grape he has ever ripened; and, he adds, that in quality, such sorts as Buckland's Sweetwater and Foster's Seedling, among earlies, are only third-rate in flavour in comparison with Raisin de Calabria. The very same remarks apply with equal force to Trebbiano and Syrian, and to that noblest-looking of all late black Grapes, Gros Colman. When well ripened, Alicantes and Lady Downes for the months of November, December, and January, are not worth eating as compared with Gros Colman.

The New Yellow-barked Peach Tree.—This is emphatically recommended for general culture by M. Carrière, editor of the *Revue Horticole*. It is perfectly hardy, its constitution is robust, and its fruit large and of excellent flavour. The yellow bark renders the tree an ornamental object in winter.

THE LIBRARY.

THE INSECT.*

Few scientific writers have the peculiar ability to divest their subject of what the general reader would call hard, dry minutiae, and clothe it with the charms of poetry that must appeal to all who are lovers of the beautiful. M. Michelet is, however, one of these, and in this, the last of his remarkable works, he has, if possible, excelled himself, and has given the world a book that, for beauty of thought, for elegance of language, and for the pure scientific knowledge that forms the basis of both, must render it a favourite both with the student of pure entomology, and with those who content themselves with a less profound but none the less charming acquaintance with the marvels of insect creation. M. Michelet has, ere this, been accused of errors and inaccuracies that a more practical and less imaginative writer would, it is said, have avoided. The accusation may, in a remote degree, be deserved, but this by no means decreases the general value of the work, for the errors are rather those of exaggeration in description than of any want of knowledge or absolute perversion of fact, and the playful fancy that gives the book so attractive a form will find its reward in the number of those who are likely, after its perusal, to take up the study of a physical science that it has been too much the fashion to decry on account of its alleged uninviting details. M. Michelet shows that a close observation of these details may be carried on side by side with, and, in fact, be the result of the tenderest sympathy with the minute objects of his interest, and that it is quite possible to give the reins to deep, impulsive, poetic feeling, and yet be fairly analytic and philosophical; this much we may say of the book itself without any wish to give more praise than is justly due.

The Woodpecker.

With respect to the illustrations, with which the work absolutely teems, it would be impossible to say too much in their favour. The fact that they are drawn by Giacomelli is a sufficient guarantee that they approach as near as possible to perfection. They must, however, be seen, for no description can convey an idea of their excellence both as regards drawing and engraving. We give two of these woodcuts as examples, with the accompanying letterpress, which will enable the reader to form his own opinion both of the beautiful language of M. Michelet and the artistic skill of M. Giacomelli. Of the Forest of Fontainebleau, M. Michelet writes as follows:

Even in the hours of silence, the forest occasionally finds a voice, a sound or a murmur which recalls to you the remembrances of life. Sometimes the industrious woodpecker, laboriously toiling at its task of excavating the Oak, cheers itself with its singular cry. Frequently the heavy hammer of the quarryman falling and falling on the sandstone, resounds in the distance with a hoarse dull echo; and, finally, if you listen attentively, you catch a significant hum and see at your feet legions of ants—countless populations, the true inhabitants of the place, speeding over the withered and falling leaves. So many images are these of persistent toil, which blend with the fanciful a serious gravity. Each in his own way digs and digs, and do thou, too, pursue thy work and exhume and stir up thy thought.

Writing of the nymph or chrysalis, M. Michelet gives us the following remarks upon that wonder of metamorphoses:

In truth it is a thing to confound and almost to terrify the imagination to think that a gnat, at the outset no bigger than a thread, should include in itself all the elements of its moultings and metamorphoses; should contain its triple and even octuple envelopes; nay, more, the sheath or case of its *nympha*, and its

* "The Insect." By Jules Michelet. With 140 Illustrations by Giacomelli. London: T. Nelson & Sons, Paternoster Row.

complete butterfly are folded up in another, with an immense apparatus of vessels—respiratory and digestive—of nerves for feeling, and muscles for moving. A prodigious system of anatomy! first traced out in complete detail in Lyonnet's colossal work on the Willow Gnat. The two-fold monster, endowed with a strong grub-stomach for the destruction of innumerable hard leaves, will possess, ere long, a light and delicate apparatus for extracting the honey of flowers. And yet the clothed creature which contains in its organism a complete silk manufactory, will almost immediately sweep away the complex system. One knows the gentle manoeuvres by which Nature conducts the young of the higher animals from the embryonic existence to the independent life, adapting the old organs to new functions. Here this is not done. It is not a simple change of condition. The destination is not merely different, but contrary, with a violent contrast. Therefore, instruments fitted for an

entirely novel existence are required, and the abolition and definitive sacrifice of the primitive organism. The revolution which, for all other beings is so well concealed, is here entirely thrown open; and we are enabled to scrutinise with our eyes this astonishing operation in numerous grubs which undergo the great change in the light of day, suspended to the branch of a tree by a silken cable. The effort is worthy of our admiration and pity. To see yonder nymph, short and feeble, soft and gelatinous, without arms or paws, contriving, by the skill with which it expands and contracts its rings, to escape from the heavy and rough machine which it was at first, flinging aside its limbs, setting free its head, and—one hardly dares to record the fact—throwing off its body and rejecting many of its principal internal organs! This little body, when it has thus escaped from its long heavy mask (living, nevertheless, but a moment since a life full of energy) will dangle and grow dry and skilfully ascend to its silken fastening. There it prepares to fix itself in a new "me" as a nymph, while its former "me" tossed about by the wind, is speedily driven I know not wither. All is, and ought to be, changed. The legs will not again be the legs. It will need lighter organs. What can the child of the air, which can balance on the point of a blade of Grass, do with these coarse short feet armed with hooks, vent holes, and so many heavy implements?

The Snowberries.—Botanists and gardeners alike have got things a little confused in regard to these plants. Dr. Asa Gray has recently contributed a paper to the "Linnean Society's Journal," clearing up some matters in relation to the botanical question; and we, *Gardeners' Monthly*, may as well say a few words as to the other. The common red Snowberry of our garden—the Indian Currant of some localities—is usually referred to in our nursery catalogues as *Symphoria glomerata*. This is Pursh's name. The generally accepted name is that of Michaux, which is *Symphoricarpos vulgaris*. It is rather common in shrubberies, but not so much so as it deserves to be. Dr. Gray makes eight species; but this is the only one with red fruit.

Dr. Gray, however, describes a new species found in Nevada, with flowers half an inch long, which he names *S. longiflorus*. Its fruit is probably white. The other species—common in gardens—is the white Snowberry, *S. racemosus*, of Michaux. These two are the only ones that seem so far to have got into cultivation. There is another species allied to the white Snowberry, which grows west of the Mississippi, and east of the Rocky Mountains, which is a stronger grower than that in our gardens, and is worth introducing. This is *S. occidentalis* of R. Brown. There is another very pretty little bushy species in Colorado, which most of us who have collected have named in our herbariums *S. montanus*. This Dr. Gray now refers to one previously named by him in Wight's Plants of Texas, *S. rotundifolius*. The true *S. montanus* is a Mexican species. Three supposed Mexican ones, including *S. montanus*, are united under the one name *S. microphyllus*. The other species not yet in cultivation,

is *S. mollis*, of Nuttall, in California, and *S. oreophilus*, which also has been confused with *S. rotundifolius*, as *S. montanus* in Colorado herbariums. In the paper Dr. Gray has some interesting observations on the nature of the fruit, showing that it is not a berry, as some botanists believe, but a species of drupe.

Movement of the Sap in Plants.—Dr. M'Nab, of Dublin, has been making a further series of experiments on the amount of transpiration from the leaves of plants and on the ascent of sap through the stem, with the following results, the plants experimented on being the Cherry Laurel (*Prunus laurocerasus*), Privet, and Elm:—1. That under favourable circumstances a rate of ascent of 40 inches in the hour can be obtained. 2. That, contrary to the generally received opinion, direct experiment has shown that the upward rapid current of sap does not cease in the evening. 3. That checking the transpiration for a short time by placing the branch in darkness does not materially retard the rapid current of water. 4. That the removal of the cortical tissues does not impede the rapid current in the stem, which moves only through the wood portion of the fibro-vascular bundles. 5. That a well-marked rapid flow of fluid will take place in a stem

after the removal of the leaves. 6. That fluid will rapidly flow downwards as well as upwards in the wood portion of the fibro-vascular bundles, as seen in a branch in which lithium citrate was applied at the top. 7. That pressure of mercury does not exert any very marked influence on the rapidity of flow, in the one experiment made with a pressure of 110.53 grammes of mercury. Dr. M'Nab points out with great force the disadvantage under which research in vegetable physiology labours in this country, from the fact that neither at Dublin nor elsewhere is there a physiological laboratory in connection with a botanical garden, a conjunction always necessary for the carrying out of original research. Physiological botany may, indeed, be said to be comparatively at a standstill in this country on this account. Some time ago, the idea was mooted of adding a laboratory to the herbarium at Kew, but, from some inexplicable cause, the project was abandoned.

Calepteryx Virgo.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Destroying Insects in Frosty Weather.—It is generally thought that a severe winter is destructive to insect life, and so it probably is to some extent; but by far the greater number of our worst garden pests get sufficiently deep down in the earth to be out of the reach of frost. There is, however, a means of effectually dealing with such as have taken up their winter quarters in uncropped ground. On a hard frosty day let it be broken up with a pick to the depth to which it is frozen, turning the lumps up as large and rough as possible, so as to be quite open, and thereby expose the under surface still further to the influence of frost. This will not only destroy thousands of slugs, snails, wireworms, and the larvæ of similar pests, but it will, at the same time, aerate and pulverise the ground to a depth that cannot be reached by any other means, thereby improving its condition for cropping.

Manuring—Use of Salt.—There is nothing in a garden that partakes more of the penny-wise principle than attempting to grow vegetables on land insufficiently manured. The amount of manure used by market gardeners, who are not likely to make mistakes in this matter, is almost incredible. On well manured ground vegetables grow quicker, and are much more tender and juicy than when produced on poor land. It therefore becomes a question with the amateur what manures he is to use; if he is so situated as to have enough horse, cow, or pig manure, without purchasing, these will, in a great measure supply all his wants; if, on the other hand, he has to purchase, I should advise him to use some proportion of light manures, of which refuse salt is an excellent fertiliser, and is especially to be recommended for dry hot soils, correcting, as it does, to some extent their aridity by the moisture which it retains in the soil. It constitutes a suitable change for land that has received heavy dressings of stable-dung for a lengthened period. It should be applied during the winter months—the earlier the better, as it thereby gets time to dissolve, and thus becomes dispersed more evenly through the soil, rendering the land in better condition for cropping than it otherwise would be, as, if the salt lies together in any considerable quantities, it would destroy such newly-sprouting seeds as came in contact with it. From half to three-fourths of a pound per square yard is a good dressing, and the latter quantity should not be exceeded. It must not be used within a yard or so of Box edgings, or it will be liable to injure the Box.

Improving the Soil of Suburban Gardens.—The innumerable small and middle-sized gardens in the neighbourhood of large towns are often deficient in two important matters, one of which is an insufficiency of soil, which generally gets buried by cold unfertile clay, taken out of the foundations of buildings, and which, instead of being put under the surface soil, by removing the latter to admit of the work being done properly, is cast on the top or mixed with it; again, where the land is naturally heavy and retentive, it may be improved by mixing it with road grit or scrapings, or anything of a similar character that can be obtained cheap. A mistaken notion prevails, that nothing will improve such soils except good loam, and where that can be had cheaply by all means use it; but, where it cannot be got, anything of a character similar to the above will be found of great assistance. The other unfavourable condition to which many small gardens are subject is the presence of stagnant water, owing to an insufficiency of drainage. This is particularly the case in heavy soils, and for a kitchen garden, where the production of early vegetables depends, in a great measure, upon the ground being dry and warm, requires the drains to be much closer than is necessary for some purposes. In a garden the drains should not be farther apart than 15 feet; the depth to drain is another important consideration, varying, as it does, with the character of the soil. Three feet may be taken as a good average depth; a 2-inch pipe will be found large enough to carry off the water, which it will generally do better than such as are larger. When laid, place on the top of the pipe a foot in depth of any material in the shape of brick rubbish or refuse from the greenhouse fires. Such drains should always, as far as possible, run straight down hill, not, as was once the practice, diagonally. Amateurs having insufficiently drained gardens, are often deterred from commencing such operations under the impression that they are costly; such, however, is not the case.

Frozen Vegetables.—Cauliflower plants in frames, and under hand-lights, especially the latter, should be carefully shaded from the sun, or they will be much more likely to be killed by it than by frost; old mats that are too far worn to be of use in other ways will answer the purpose for covering the lights, and stable litter will do for the hand-lights, around which nothing is so good as Spruce branches stuck in the ground sufficiently firm not to be removed by wind. Lettuce should be treated in a similar manner, both in frames and under walls; in the latter situation, boards laid on their edge

slanting over, but not so as to touch the plants, and a good sprinkling of Spruce branches stuck in over all will be found to be useful; a few of the latter stuck amongst spring Cabbages will also cost little labour, and will frequently prevent the crop from being much injured. Attention to these and similar small matters constitutes the difference in gardening between successful and indifferent results. Should frost again set in, see that Potatoes, Beet, and Carrots, in stores are not frozen; dry litter or straw is the best material with which to cover them. Now is a good time to procure and prepare Pea sticks, and also those wanted for Runner Beans; by doing this work thus early, time is saved later on, when it is required more directly in attending to other matters.

Early Cucumbers.—Where means exist of growing early Cucumbers, either in a plant stove or heated pit, in which a temperature of 60° can be maintained at night, it is not a bad practice to sow a few seeds three different times during the month, as, if anything happens to the earliest sown plants, there are others to fall back upon. They are much the best sown singly in small pots, as by this method there is no mutilation of the roots by dividing the plants when re-potting. Put a small bit of flaky leaf soil or fibrous loam in the bottom of each pot; this will be drainage enough for the short time during which the plants remain in pots before being removed. Ordinary loam, with one-fourth of sifted leaf mould and a little sand, will be suitable material in which to sow the seed, which should not be covered more than half an inch, or fill the pots more than two-thirds full of soil at the time of sowing; this will leave room to add more when the plants have attained a few inches in height, and will induce them to throw out roots up the stem, which tend much to strengthen them. For ordinary purposes, few sorts equal the Telegraph, where it can be had true. It is an abundant and continuous bearer, but so free is it that, if the fruits are not well thinned, the plants will soon exhaust themselves with overbearing.

The Greenhouse.—Place in heat Hyacinths, Narcissus, and Crocuses, so as to bring them into flower, but see that they are well supplied with roots before being thus excited, for upon this, in a great measure, depends their ability to flower strongly. Keep them close to the glass, or they will bloom weakly and have a poor appearance. Care, so far as possible, should be taken that the frost does not reach anything that it will injure in either pits or frames, such as bedding plants or general greenhouse stock; but if it should happen that, through an insufficiency of heating power or an extraordinary severe night, anything should get frozen, the first thing to do should be to get up the heat a few degrees above the freezing point, closely shade the plants, and then syringe them freely overhead with cold water, keeping them as dark as possible for a few days. This mitigates the effects of frost, and, with some things, is effectual if they have not been too much frozen or not in a very luxuriant state of growth, which latter naturally tends to make all plants more susceptible to injury from too low a temperature than when less vigorous.

Exhibition Stands for Cut Flowers.—The following is the standard adopted by the Royal Horticultural Society for the stands in which cut flowers are staged at its exhibitions. Such stands should be painted green, or covered with green baize:

			Length.	Breadth.
48 Dahlias . . .	2 stands . . .	4 ft. 0 in. . . .	1 ft. 6 in.	
36 " . . .	3 " . . .	2 " 0 "	1 " 6 "	
24 " . . .	1 stand . . .	4 " 0 "	1 " 6 "	
12 " . . .	1 " . . .	2 " 0 "	1 " 6 "	
24 Gladioli . . .	2 stands . . .	3 " 0 "	2 " 0 "	
12 " . . .	1 stand . . .	3 " 0 "	2 " 0 "	
24 Asters . . .	1 " . . .	2 " 6 "	1 " 6 "	

Height of stand to be 6 inches behind and 4 inches in front. Stands for cut Roses and Hollyhocks to be of the same size and height as the foregoing.

The Results of the Late Severe Weather.—Now that a change in the weather has taken place, some estimate may be formed of the damage (if any) done by the late severe frost. On the night of the 29th ult. the thermometer here fell to 8°, or 24° of frost, which is the lowest temperature we have experienced since 1870. Fortunately, the covering of snow—assisted in some instances, where necessary, by other materials—has, as far as can be judged at present, kept things fairly safe. Even Broccoli, that rarely survives when the thermometer falls below 10°, seems to have passed through the ordeal unscathed. Rain commenced falling in the evening of the 1st inst.; but it froze as fast as it fell, and, on the morning of the 2nd, every place, walk, road, and street, was one complete mass of ice, and locomotion, except on skates, was a work of both danger and difficulty: since then the thaw has been exceedingly rapid, and the snow and ice are fast disappearing.—E. HOBDAV, Ramsey Abbey.

INDOOR CLIMBING PLANTS.

By T. BAINES.

BETWIXT roof climbers and such plants as occupy the body of a glass structure under their shade there must, of necessity, be a compromise as regards general treatment. In times past, owing to the striking effect which roof-climbers produced, they were often considered to be more important than the general collection of plants grown under them; from the time when it became a recognised principle in indoor gardening that each plant should receive the treatment requisite to give it an opportunity of, in some measure, exemplifying its natural character, plants for roof embellishment have not been so generally grown as before, and, in many instances have been dispensed with altogether; but in this, as in most matters of a kindred character, it is in the extremes of indiscriminate use or rejection that the mistake lies. There is no position we can assign to a plant suitable for the purpose, wherein it will be seen to such advantage, or where it adds so much to the appearance of the place it occupies, as trained tastefully on the roof of a plant house, allowing it sufficient freedom to hang in graceful festoons—and in such situations as plants of this description are adapted for, they should always be present, it not being possible by any other means to make up for their absence. Before light span-roofed houses were much thought of, or in use, the old lean-to, with its dark heavy roof and high back-wall excluding the light, was a place in which plant life in general had a hard struggle to exist, without the additional light-intercepting influences of roof-climbers, which usually were to be found upon every rafter, each one of which usually had its separate species of plant, forming a dense mass of growth, meeting its neighbours half-way across the lights, with their small squares and wide dirty laps, the combined influence of which was such as to make the house nothing better than a living sepulchre, in which the other inmates struggled for existence as long as they were able, but ultimately succumbed, and found their way to the rubbish heap, making room for others to undergo a similar ordeal, and conclude their existence in a like manner. In such houses as the above roof climbers were out of place; nothing they could add by their appearance compensated for the injury they inflicted upon the plants placed underneath them. Great mistakes were, and are now, often made in the selection of particular plants for this

roof drapery—large heavy-leaved subjects, such as *Passiflora quadrangularis* being employed (in stoves with not much light to begin with)—fine in itself, undoubtedly, but, in addition to its vigorous growth, possessing foliage of such size as to darken everything underneath it. It should always be remembered that the great majority of the different plants we grow in our stoves and temperate plant-houses are indigenous to countries where they receive much more light than this country affords, without taking into account the light-excluding and absorbing influences of the best constructed modern plant-houses. Even in the case of such plants as occupy our stoves, which, in their native habitats, are continuously under the shade of overhanging evergreen arborescent vegetable life, the light they receive in a state of Nature is quite different from what we can give them in our cloudy atmosphere; a condition further aggravated by the comparatively small amount of fresh air that plants living in a glass erection can receive, especially where an artificial high temperature has to be kept up by the use of fire heat, to the necessary exclusion of air. It then becomes a question where plants should be employed for the purposes of roof drapery and where they should be omitted, as also what plants to select for the purpose. In ordinary houses devoted to the growth of greenhouse subjects, hard or soft-wooded, either as permanently occupying such houses or in preparation for removal to conservatories, corridors, or similar places, the plants require all the light they can get; consequently, nothing in the shape of roof climbers should ever be allowed, especially where any attempt is made to grow the plants up to the standard generally required at the present day. If climbers are allowed to grow in such a case as this, they should be used sparingly, and they should be such as will not grow too rampant, be planted at a considerable distance apart, and kept well within bounds. The places where these roof-plants are most appropriate, or rather indispensable, are in houses where a considerable number of the occupants are planted out with a view to produce, as far as possible, natural effects, and in glass-covered corridors. A great number of the plants only remain in such structures as these whilst in flower, and in this state most things do not suffer to any appreciable extent, if not kept too long or too much crowded; this is consequent upon the comparatively little or no leaf-growth that takes place whilst the plants are flowering; the different subjects that are usually planted out in the conservatory are generally such as will not receive injury from partial shade, such, for instance, as Camellias, which rather enjoy it in moderation whilst making their growth; in houses, also, where most of the different subjects grown are planted out with a view to, as far as possible, produce a natural effect; and, to secure such, it is necessary to keep them at a considerable distance apart; here roof-drapery is indispensable, and can be used to the best advantage. Having considered the situations where these descriptions of plants can be best employed, it will not be out of place to indicate such as are best adapted for the different situations, in large or small houses, with difference in temperature, soil, moisture, &c., required by each. First as to those which require a greenhouse temperature, and are suitable for a cool conservatory or where there is little more heat kept up than will maintain flowering plants through the winter in good condition. Here it may be observed, that many of the best and most suitable are such as do not possess naturally a twining habit, and, consequently, cannot attach themselves to wires or other contrivances for their support.

Cool Conservatory Climbers.

Tacsonia Van Volxemii.—As a plant for roof decoration, which will grow freely, and which can also be kept in moderate bounds without using the knife to such an extent as to interfere with its flowering, there are few, if any, plants that surpass this *Tacsonia*; it is a profuse bloomer, its finely-coloured crimson flowers literally hanging in wreaths for months together; the shoots should be allowed to hang down for a yard or two, according to the height at command. Grown in this manner nothing can be finer; it requires a fair amount of root-room, in good sandy loam, well drained, with an occasional application of liquid manure, through the growing season and in the spring the removal of an inch or two of the surface-soil, adding some new, well-enriched with thoroughly rotten manure. After the flower-

ing season is over it may be cut in as far as is deemed necessary for the space at command, and the nature of the situation it occupies.

T. sanguinea is another fine plant much after the general habit of the last.

Plumbago capensis.—A plant totally different in habit from the foregoing; a good free grower and bloomer, its flowers, pale blue, are produced in bunches. This forms an excellent contrast to the above; it is, like them, a comparatively clean plant, not being so subject to insects as some others, but, to grow it well, it must be encouraged by the application of liquid manure, and the yearly addition of fresh surface-soil, otherwise its gets weak, and makes comparatively poor flowers. It is also most suitable for a back wall, or training round a pillar.

Lapageria rosea.—This is now well known for the quantities of rosy-crimson bell-shaped flowers it produces when in good condition; it is a plant of moderate growth, that likes a good, rich, sandy loam, well drained, on account of the liberal supply of water it requires when in full growth. It is from the Chilian Andes, found at a considerable elevation, and requires nothing more than protection from frost, but the young shoots are impatient of the direct action of the sun, whilst the leaves are not fully developed, consequently, it should in this stage, have a little shade. The mistake which many at first made in the cultivation of this *Lapageria*, was in planting it out too soon; a small ordinary trade-sized plant, takes a couple of years to get into a strong state, and, during this time it should be kept in a pot, moving it on into a larger size as the roots require it, and when it gets strong and has plenty of roots to lay hold of the soil in which it is turned out at once, it should be planted out, otherwise, the too great body of earth becomes sour before the roots exist in sufficient quantities to freely extend all through it.

Lapageria alba is an exact counterpart of the red variety in every way, except the colour of the flower, which is pure white, and one of the very finest plants ever introduced into the country. Both varieties make fine pillar plants, or to form an arch over a conservatory path, in which positions their young growth is farther from the roof glass, and not so likely to receive injury from the sun whilst in a tender state.

Tecoma capensis is another good climber of moderate growth, but not too rampant. It produces its yellow flowers in bunches, from shoots of moderate strength. It is from the Cape, and succeeds well in sandy loam. It does not require, when once well established, so much assistance at the roots, in the shape of manure-water or rich soil, as some plants; its shoots being in a pendent form, well answering the purpose of relieving the objectionable appearance of bare rafters.

Mandevilla suaveolens.—A free-growing plant from Buenos Ayres, with highly-perfumed, white, trumpet-shaped flowers, produced in bunches from the points of the shoots. It is not so generally known or grown as it ought to be, requiring a considerable amount of room to fully develop itself; it needs a moderate amount of root-room, in good turfy sandy loam, assisted through the growing season with liquid manure. The plant is subject to red spider, to keep down which it should be well syringed two or three times a week through the season of growth; the flowers are fine for cutting.

Clematis indivisa.—This is a white-flowered plant, from New Zealand; it is a very free grower, and a most useful plant for the production of cut flowers, a consideration that should by no means be lost sight of, for if in these roof plants such are grown as will furnish in quantity flowers for cutting, it is an advantage. This is a strong grower, and is suitable for a large house; where it can have space to run, it will grow in any kind of soil, and is not subject to insects. The plant will bear a free use of the knife after flowering.

Passifloras are general favourites, and there are several that can be used as cool conservatory roof plants, amongst which may especially be mentioned the free-flowering light-coloured *P. onychina*, the white *P. Hartwegiana*, and *P. Imperatrice Eugenie*, white sepals, and pale pink petals. These are plants of moderate growth, free bloomers, and, from the pendulous habit of the flowering shoots, are well adapted for the purposes under consideration.

Acacia pubescens, from New South Wales, and **A. lophantha**, from New Holland, are fitting subjects for the roof of a conservatory, but are better adapted for a place at the end, especially if such should be a dead wall, as, abutting on a dwelling-house, in such a situation, they produce a fine effect when they reach the roof and are allowed to extend a little. The above *Acacias* are very distinct in habit; the latter (*A. lophantha*) is a fine plant for cutting; the leaves are almost Fern-like, stand well when cut, and are especially adapted for mixing with cut flowers for the decoration of large vases, for which purpose this plant cannot be surpassed.

Hovea Celsi is a native of New Holland, and although seldom used for the purpose, is a beautiful object in flower on a conservatory pillar or a light corner, its deep blue flowers being so distinct; but

where it is the intention to place this *Hovea* in such a situation, the plant must be first grown to a moderate size before turning out in the open border, so as to have it furnished with a fair amount of roots previously.

Cassia corymbosa, from Buenos Ayres, is also a plant very seldom seen planted out in a conservatory, but for covering a wall or pillar it has few equals. Those who have only seen this *Cassia* grown as a pot specimen cannot form the slightest idea of what it is when allowed sufficient root and head room. So treated, it blooms for six months in the year, its beautiful green healthy foliage setting off the bright yellow flowers to the best advantage.

Clanthus magnificus.—This free-flowering form of the Glory Pea makes an excellent pillar-plant; it is very attractive and distinct, not requiring a great deal of root room, but must, like the other species of this family, be regularly syringed to keep down red spider.

The above are a few of the best plants that can possibly be used for furnishing the roof and pillars of a cool conservatory; many others are often to be met with in such situations. Some very unsuitable, either through their weak habit of growth and insignificant appearance, or the opposite defect of being so rampant as to smother everything under them unless the knife is kept so continuously in use as not to allow their ever exhibiting their true character; it also often happens that plants are recommended as greenhouse climbers that require an intermediate temperature, and do not succeed for want of sufficient heat. A few of the best for an intermediate house I will name and endeavour to describe.

Climbers for an Intermediate House.

Bougainvillea glabra stands unequalled as a roof-plant, or even if kept within the bounds of a pillar, but the temperature should not in the winter fall below 46° or, if it can be kept to that, 50°. This plant will repay the grower better than any other with which I am acquainted; it is a vigorous grower, and should have a fair amount of root room; the points of every shoot it makes will become clothed for a foot or more in length with its lovely mauve-coloured bracts, continuing to open uninterruptedly a succession of flowers for months during the summer and autumn; it will grow in either peat or loam, but requires liberal feeding with manure-water.

Abutilon Duc de Malakoff is a strong growing plant, well adapted for a similar temperature, its distinct bell-shaped flowers contrasting well with anything else. The beautiful white variety, *Boule de Neige*, is also a most desirable plant for a pillar, flowering at almost every leaf it forms, and, if a temperature of 50° is maintained in the night through the winter, it will bloom almost continuously.

Habrothamnus elegans is a native of Mexico, and is another useful free-flowering plant, producing its purple flowers in terminal bunches, at the extremity of almost every shoot nearly all the year round, and if kept a little warm through the winter will continue blooming; it succeeds best in loam.

Clerodendron Balfourii is one of the freest growing and equally free flowering plants we possess, little subject to the attacks of insects, but will do the best grown in a large pot and kept at the warmest end of the house; it does not like a lower temperature than 48° or 50°, and in the winter it should have water withheld so as to induce the leaves to ripen and fall off, receiving only a little at long intervals, until it shows signs of the buds swelling in the spring, when the ball should be soaked by steeping it for several hours in a vessel full of tepid water, until it is thoroughly moistened, when it will grow and flower from every joint, after which it may be, as far as desirable, reduced with a knife.

Stephanotis floribunda is a universal favourite and will succeed well with similar treatment as far as being grown in a pot goes, but it will not require so much root-room as the *Clerodendron*; neither should it have its roots interfered with much, for when it once gets large enough to occupy a pot 15 or 18 inches in diameter, it will not require to be moved for several years, further than seeing that the drainage is right; give it manure-water once a week during the growing season; the reason for not turning this plant out into the open border in a situation where the temperature is not kept higher than above indicated during the winter is, that if the roots were placed in a large body of soil there would be a difficulty in keeping it dry enough to preserve them, especially if in soil partially occupied by other plants which would not bear this dry treatment; this plant, in such a situation, only requires a little water through the winter when the leaves show signs of shrivelling.

Jasminum Duchesse d'Orleans.—A double white variety, very large and full; is a plant well worth a place here, but should also be grown in a pot, in sandy loam; its fragrant flowers are most useful for cutting.

Luculia gratissima from Nepal.—This old but beautiful free-flowering plant is one of the finest to occupy a corner of the inter-

mediate house or on a back wall, it well deserves a place, producing, as it does, for a considerable time its large bunches of sweet-scented pink-coloured flowers.

Climbers for a Stove.

In large stoves, or where a conservatory is kept up to a moderate stove temperature, say not usually lower than 55° in the night during winter, most stove climbers will do even better than where the temperature is correspondingly higher winter and summer, provided the plants are kept tolerably dry at the root when at rest. Many stove-climbers, when grown in a very hot house, especially if planted out, continue growing at such a rate as to appear not to get rest enough to induce a flowering disposition. In a winter temperature, such as above indicated, *Allamandas* will succeed well in pots, or, if planted out, the space devoted to their roots should be limited, or they are apt to get so strong as to completely smother everything near them. The roots should be for a time during the winter kept quite dry, and the shoots well cut in; they will bear a free use of the knife. The two varieties most suitable are *A. grandiflora* and *A. Chelsoni*, which are the freest flowerers and smallest-leaved sorts; they succeed the best in good loam.

Hexacentris mysorensis, from Mysore, is a fine plant for a roof-climber, producing freely its gorgeous racemes of red and yellow flowers. It is not so strong a grower as the *Allamandas*, and is much more elegant in habit.

Combretum purpureum, from Madagascar, is a moderate-growing plant, producing very remarkable reddish-purple flowers. It does the best in a large pot, or, if planted out in a confined space, where the roots of the more vigorous climbers can be excluded, otherwise they will impoverish the soil of this and similar moderate-growing subjects, so as to give them little chance.

Clerodendron splendens is a moderate-sized red-flowered plant, from Sierra Leone, a good, but not over vigorous grower, requiring similar treatment as to root room to the *Combretum*, and, like it, is more suitable for clothing a pillar than making much way on the roof; both plants do well in sandy loam, and need little use of the knife.

Stephanotis must also have a place here, and will do well planted out in a moderately confined space, keeping it dry at the roots during the season of rest, and cutting it as far as requisite after flowering.

Passiflora quadrangularis.—This magnificent and singular flowered plant is a native of Madagascar, and is most suitable for covering a back wall, or, if allowed a place on the roof, it should not have too much root room, or it becomes almost unmanageable; it may be cut in moderately after flowering; it does well in loam, which, with most of these climbers, especially such as are vigorous growers, induces a freer flowering disposition than peat. The fine crimson *P. kermesina* is one of the best for a place here, it will run a considerable distance if allowed space, and should be kept in bounds by a free use of the knife, and not allowed too much root room.

P. Decaisneana is also a good variety, and well worth a place, treating it similarly to the last.

Ipomoea Horsfalliae, is a good free-flowering plant, not so strong or rambling a grower as some, and is most suitable for a pot, or confined space if planted out; producing its rosy-coloured flowers in bunches for a long time in succession.

Of *Dipladenias*, all fine climbers, *amabilis*, *Brearleyana*, *insignis*, and *Williamsii*, are the best, and all deserve a place in even the most select collection of plants, but if planted out, the space allotted to their roots should not be too large, for if the soil ever gets too wet it will rot them to their certain destruction; they are the most suitable for pot culture. The three first-named are all different shades of red and crimson, the latter, *Williamsii*, is a splendid pale blush, with deep rose in the centre; all are garden hybrids, and require good fibrous peat, with a liberal admixture of sand. If a singular-looking flower is wanted, *Aristolochia gigas*, or *A. ornithocephala*—the former from Guatemala, the latter from Brazil, may be grown; both are very strong free-growing plants, and do well in a pot in loamy soil. They produce their large, most singular flowers very freely, from the young shoots during the summer, and bear cutting well back afterwards, but from their free growth they exhaust the soil very soon, consequently they require liberal feeding with liquid manure, and the soil partially removed each season before they commence growth. *Bougainvillea glabra*, and the still higher coloured, *B. spectabilis*, should one or both find a place here, drying them off thoroughly after they have made their season's growth, and cutting in as required before they start in the spring. The last named variety is the most suitable for a very large house on account of the room it occupies.

Euphorbia jacquiniæflora, from Mexico, is a most useful and continuous winter flowering plant, and, for a wall in a warm stove,

there is nothing more appropriate, or has a better appearance; in such a situation it is most beautiful, planted out in a limited space in good loam; it must never be over-watered, especially after being cut back after it has bloomed, or its roots will be almost sure to rot, after which it will never recover. The foregoing comprise a selection for the different temperatures indicated, and cannot fail to give satisfaction; but, in commencing their cultivation, care should be taken that they are free from the worst species of insects, such as mealy bug, white and brown scale, and also that no affected plants are placed so near them as to admit of their getting infested with these pests, or the work entailed will be endless, and, in addition, every plant on which these insects will live that is placed under roof-plants so affected, is certain to catch the insects from them; this, in particular, applies to the plants recommended for the cool conservatory, if the plants here on the roof get affected with that worst of all insects, white scale, there is no remedy but cutting all the branches away, and repeatedly scrubbing the stems with a strong solution of some insecticide that will destroy the insect, which must be thoroughly exterminated before the headed-down plants break, as the young growth will not stand the mixture strong enough to kill the insects. In the planting and after-management of roof-climbers there are two things that should always be observed, never to plant too many subjects to overcrowd the house, or to allow the whole area of the roof to be covered as is sometimes seen; this not only defeats the object in view, which is to embellish the house, not to make it an interminable thicket of running shoots, which destroy everything under them, and ultimately have to be cut out. The training should be regularly attended to as required, not allowing the plants to become entangled with one another or in themselves, and the thinning out and general use of the knife should also be continuous, so far as possible, without interfering with the flowering of the plants; by such means the effect produced will be more natural in appearance than it otherwise would be.

WAITING FOR SPRING.

THOU of the sunny head,
With Lilies garlanded,
And bosom fairer than the blown sea-foam;
O Spring, in what waste desert dost thou stay,
Whilst leaves await thy presence to unfold?
The branches of the Lime with frost are gray,
And all imprisoned is the Crocus' gold.
Come, sweet enchantress, come!

Arise, and bring with thee
The rathe bud for the tree,
The healing sunshine for the trampled Grass;
Loose tendrils for the boughs which bless the eaves,
And shield the swallows in the rainy hours,
The pendent flames which the Laburnum heaves,
And faint scents for the wind-stirred Lilac flowers.
Enchantress, breathe and pass!

The larks shall sing again,
Between the sun and rain,
The brown bee through the flowered pastures roam,
There shall be music in the frozen woods
A gurgling carol in the rushing brook,
An odour in the half-unbosomed buds,
And dancing Foxgloves in each forest nook:
Then come, enchantress, come!

—Chambers's Journal.

How to Treat Imported Bulbs of *Gloriosa superba*.—Kindly inform me how and when to plant bulbs of *Gloriosa superba* sent to me from India? —HIMALAYA. [Imported bulbs or tubers of *Gloriosa superba* should be kept perfectly at rest in pots filled with parched dry soil or sand until March or April; then plant each tuber in an 8, 10, or 12-inch pot, according to size, in a compost consisting of three parts friable turfy loam and one of turfy peat, to which a little leaf mould and sand have been added. Cover the bulbs from 1 to 2 inches deep, and place them in the warmest part of a stove; keep them nearly dry until they begin to grow, after which water as required, but at first not oftener than once on alternate days. Increase the root temperature by partially plunging the pots (if practical) in some warm material until vigorous growth has been induced; then gradually remove them from bottom-heat, and encourage growth by exposure to full light and a moist genial atmosphere; and this treatment should be continued until they have made their growth and have begun to bloom. When done blooming, they should have a perfectly dry period of warm rest in the pots until they are started again into growth, which should be slowly at first, under a high temperature in a moist warm stove; but when they have made their growth, they should be bloomed in a drier atmosphere. To avoid injury from undue contact with moisture, the tubers should not be broken, cut, or bruised when planted. Being somewhat difficult to re-pot or shift during growth, each tuber should be at once placed in the pot in which it is to be flowered, in the soil named, with proportionate, not excessive drainage.]

THE KITCHEN GARDEN.

COBBETT'S CORN.

MR. WILLIAM COBBETT, a son of the celebrated William Cobbett, of political fame, when travelling in the United States, during his father's lifetime, sent home some cobs of the Indian Corn or Maize, so abundant in that country. The elder Cobbett at once concluded that he had here found the antidote for the Potato "fever," and a substitute for that vegetable, to which he had conceived such a violent antipathy. Cobbett's Corn was advertised, proclaimed, and applauded all over the kingdom, and thousands of enthusiasts bought seed of it and grew it, but somehow the crops failed to ripen properly, and much disappointment followed. The taste for the Potato increased, and the demand for the Corn died out. The present Mr. William Cobbett has long since discontinued growing that kind of Corn, which he found ill suited for cultivation in a climate where, as in England, the summers are short and uncertain; but he still entertains the belief that there is a kind of Indian Corn or Maize that would ripen here under ordinary culture, and that he now possesses the stock of such a variety, I am, from personal observation, assured. During the past summer in an adjoining garden, he has grown a capital crop of this particular kind, the "Improved Cobbett's Corn," and, although not sown earlier than the middle of April, the crop had ripened and was harvested before the end of September—many of the best cobs having been gathered even a few weeks earlier. This was grown in ordinary garden soil, prepared by digging and manuring as for any ordinary garden crop, and with after cultivation of the simplest kind. The best way to grow it appears to be to have the soil thrown up into ridges, of which the width apart depends on the method of after-cultivation to be adopted, whether by hand or by the plough. Mr. Cobbett informs me that in the States it is the practice to cultivate it in hills 4 feet apart each way, thus leaving, whilst the plant is yet young, ample space to work the plough amongst them for earthing up. Mr. Cobbett, although his crop was cultivated by hand labour, grew it in rows 4 feet apart, but I was satisfied that equally as good a crop could have been produced at 30 inches between the rows, as that would give ample space for earth to be drawn to the roots by hand-labour. If the crop be grown largely and the plough be required to cultivate the soil between the rows, not less than 4 feet space should be allowed from row to row, and after the earthing up is performed, a row of Swede or white Turnips might be sown in each intermediate space, and thus the ground would be utilised to the fullest extent. To prepare for the reception of the seed-corn the soil should be thrown into ridges, and then be slightly flattened with a light roller; the seed is then dibbled into the centre of each ridge in holes about 4 inches apart and 3 inches in depth. It soon germinates, and, as it throws up a shoot that is sweet and tender like that of a Pea, it is eagerly sought for by birds, who will attack it vigorously unless they be kept at a safe distance; as soon, however, as it is well through the ground it is safe. The course of treatment required during growth is simple enough. If in a small patch, a good flat hoeing, followed, when the plants are 12 inches in height, by a good earthing up, suffices until the Corn is ready for the harvest. If grown largely in the open field, then the liberal use of the horse hoe must be succeeded by the earthing plough, the object of this earthing up being to give the plants the requisite support in case of rough winds and storms prevailing. As we usually get the strongest gales from the south-west, it is well, in sowing, to have the rows running from that point of the compass, as the wind, being at liberty to sweep along between the lines, is productive of much less mischief than if the rows be at right angles to the direction of the storm. Grown in good soil, the new Cobbett's Corn does not exceed 4 feet in height, and it is far from being so coarse-growing a variety as we have hitherto been familiar with. It is one of the peculiar features of the Maize crop that it can be harvested at any time, as, whilst still standing, it suffers neither from frost nor rain. Each cob is furnished by Nature with an external leafy covering that effectually protects the Corn from moisture. The covering is of a stout fibry texture, and, as the weather becomes moist it contracts itself closely around the Corn, and keeps it quite dry; still, should it get at times a little damp, it soon dries again when fair weather ensues, so that no harm is done. Probably, at no time could Maize be better harvested than in dry frosty weather, but the question of harvesting would be, of necessity, a question of convenience. A stalk will produce from four to six cobs, the finest being at the bottom. A good cob contains about 240 corns, which, when ripe, are of a rich golden-yellow hue. I found, as a rule, that the best cobs grown by Mr. Cobbett had eight rows of Corn, thirty in a row, laid together in the most perfect order, and, although much finer cobs may be grown, certainly none could be more handsome. To preserve them clean and bright for a considerable period, it is

desirable to strip off the outer leafage, leaving only the inner one, and, if this be tied round at the top of the cob, it will keep it fresh and clean for a long time. It appears to be the rule to pull the cobs whilst the straw is standing, after which it is cut close to the ground and carted away. The straw is useful as a winter covering, as, owing to its stout fibry texture, it does not decay so speedily as ordinary straw. One characteristic which should not be overlooked is that the plant throws up suckers from its base. These are not fruitful, and should be cut clean away before the final earthing up is given, otherwise the crop will suffer. The uses to which this Corn may be put are many and various, and it is one of the most nutritious of all articles of diet; it is evident that, if successfully cultivated in this country, its proving a profitable article of culture must mainly depend upon its mode of manufacture. There are machines for "dis-cobing" the corn, and any mill that would grind Peas or Wheat should also as effectually grind it. The Corn is with us largely used as food for poultry and for horses, both whole and in a crushed state; it enters largely into the composition of bread, as is evidenced when the bread crumbles instead of being cut clean by the knife. The flour of this Corn forms a delicious diet for infants and for invalids; it makes puddings and blanc mange, and, in the hands of a clever housewife, will make us sweet crisp cakes. Whether or not it will prove a paying crop depends mainly on the cost of cultivation. A. D.

* GROWING POTATOES FOR EXHIBITION.

IN growing Potatoes for exhibition, one of the first considerations is soil. Some soils will always grow Potatoes well, such, for example, as a deep friable sandy-black loam, that is either naturally or artificially obtained, but then such a soil as this is far from common, and therefore the cultivator has to make the best of that of which his garden consists. If your correspondent who wants information about growing Potatoes for exhibition has a soil that is naturally heavy, he will do well to work into it as speedily as possible a liberal dressing of long fresh stable manure, burying as much of the straw as possible. This should be dug in with a long tined fork, and the soil should be as much broken as possible. After resting a few weeks, let the ground be marked out with a line in lengths of 3 feet in width, and each length should be thrown into a ridge, the centre spit being turned over first, and the two side spits thrown up on to it. In this state it should lay until planting time, just prior to which, however, it will be well to add a dressing a few inches in depth along each trench, of either rotten leaf soil or of vegetable refuse from the rubbish heap. This should be well forked into the trench, in order that there may be good depth of well-worked soil below the seed tubers. Still farther, a good dressing of slaked lime one half, soot one quarter, and guano one quarter, may be sown with advantage along each furrow, and be lightly pushed in when ready for planting. A shallow drill drawn with the hoe will be all the remaining preparation needed. Lime, newly slaked, and soot are important ingredients in the cultivation of show Potatoes, as they keep off wireworms and promote that smoothness and cleanness of skin so essential to a handsome Potatoe. If the soil be light, a good dressing of well-rotted manure should be worked into it in autumn, and in spring, just before planting, a dressing of lime (as just mentioned) should be applied all over the surface, and as planting proceeds this will be forked in, the lines in this case being, as before, not less than 3 feet apart. As to sets, preference should be given to such as weigh about 3 ounces each, and they should be selected early in spring, and be laid out singly either on shelves or in shallow boxes exposed to the light, so that when they break the shoots may be strong and healthy. Shortly before planting, and when the strongest eyes have pushed into growth, the whole of the sets should be gone over, and have all their eyes gouged out with a sharp knife, excepting always the strongest, as that alone is amply sufficient to produce a good crop, and the tubers will be larger than if three or four eyes are allowed to grow. As to planting, the second week in April is early enough. If the ground has been ridged it is simply necessary, as has been stated, to draw a shallow drill, place the sets firmly in it at intervals of about 15 inches, and then lightly and carefully cover them with the finest soil from the sides of the ridges to a depth of about 5 inches. Nothing more need be done until they are well through the ground, when the ridges between the rows should be again forked up, as it is only by constant working that a stiff stubborn soil can be brought into a good free tilth. Planting on the level light soil should be done in rows at the same intervals of 3 feet, using a fork to move the soil to a depth of about 6 inches. Thus a shallow trench is opened across at one end of the piece to be planted about 1½ feet from the edge, and a line being strained along it, the seed tubers are placed in it carefully, and the same width apart as before mentioned.

The soil is then carefully forked over on to these, and the forking is continued until another width of 3 feet is accomplished, when another line of sets should be planted as before, and so on until all are in the ground. Distinct kinds should be marked with a large label, to prevent any possible mistake. In both cases it is best to stir the soil around the haulm with a fork rather than with a hoe; the earthing up, which should be done twice (an interval of two weeks being allowed to elapse between each operation), should also be done with the fork. Beyond keeping the ground free from weeds, little else is required, and if the sorts selected are good, and the season favourable, good crops ought to be the result.—A. DEAN, *Bedfont*.

FRENCH BEAN FORCING AT BURGHLEY.

SOME of our great gardeners have remarked that they have French Beans and Grapes all the year round, but is that requisite? It is well known that, if these things are supplied daily, they become commonplace; whereas, if we are without them—say in both cases a couple of months—they are then not only something fresh, but are enjoyed far better. When I first began to crock pots for French Beans, we used to put half a dozen Beans in an 8-inch pot only half filled with compost, which consisted of old Mushroom-dung—and for very early forcing, I know of nothing better. At that time, however, glasshouses were not so plentiful as now; the Pine-stove and early Vineries were the only places available for such crops. Some short time since, I noticed, in a contemporary, that French Beans were earthed up (just because our grandfathers earthed them up, and for no other reason), as no roots ever pushed from the stem. But I have repeatedly seen them well rooted nearly to their first leaves. We have here a span-roof house, 60 feet long, divided in the middle; half is used for winter Cucumbers, and the other half for French Beans in winter, and both portions are used in summer for Melons, of which we want a succession all through the summer months. Our first lot of Beans was sown in 3-inch pots on the 11th of October, and the first dish was gathered November 25th and the usual practice is to have three successions; whenever the first is thrown away, another batch of fifty pots is sown, so that a full succession is always maintained. The general soil for them in winter is light turfy material enriched with rotten leaves. They are shifted from small pots just as the second leaf is showing, an operation in which they receive a slight check, which prevents them making too much growth and too few pods. They are placed at once on the shelves. When growth commences, I take out their points to make them stubby. They should also be surrounded with small spray, and one piece of matting should be put round each, to keep it in form. No manure-water should be used until the Beans are formed, when they should be well supplied with it. Respecting temperature, I never like to almost freeze my pots at night and parboil them during the day, but give them from 60° to 68° at night, and let the thermometer run up to 75° or 80° by sun-heat; and on every possible occasion give air, if only for an hour. French Beans are troublesome things to keep clear of red spider; but by syringing overhead daily, and keeping all about them moist, they will not give much trouble. The great variety of these Beans now in the market somewhat perplexes us; but of all that have come under my notice, Canadian Wonder is the best, and it is the only sort which I grow. But there is more than one variety sold under that name. By growing this Bean one is rewarded by fine straight pods 6 inches long, as green as Grass, perfectly tender, and of delicious flavour.—R. GILBERT, *in the Gardener*.

New Potato Disease.—A new Potato disease has made its appearance in Algeria within the last two years, and has totally destroyed two-thirds of the crops, and threatens to do even a larger amount of injury. Potatoes attacked by the pest are utterly worthless for any purpose whatever. No animal will eat them, and, on opening the tubers, it is found that they are honeycombed in the centre, and filled with a blackish matter that gives forth a very offensive odour. It is not the *Botrytis infestans* that is causing the damage, but a very minute insect of the *Lepidoptera* order, of which the history is little known. It is only supposed that the larvæ germinate in the roots of various vegetables. The small moth deposits its eggs upon the young shoots of the Potato the moment they appear above the ground. As soon as the eggs are hatched, the small caterpillar, as slender as horse-hair, penetrates into the stem, and works its way down into the tuber, the interior of which it eats away. The grub which works the mischief is unknown in Europe, and the name has been given to it of *Bryotropha solanella*. The "Journal of the Central Society of Horticulture of France" warns Potato-growers against planting Algerian Potatoes, for fear the disease may be introduced into France.

GARDENING FOR THE WEEK.

Kitchen Garden.

EVERY garden, where early vegetables are a desideratum, should be provided with a number of those cheap portable frames and lights of which many forms and designs are now met with; it is hardly necessary to particularise any special form, as they are all useful, from the old-fashioned hand-light to the more elaborate designs now frequently advertised; but, whatever shape they may assume, protection from the cold, and concentration of the sun's warmth, by means of glass, is their chief aim and object. I think, if I am not mistaken, Mr. Rivers was amongst the first to advocate the extended use of such glass frames; and his ground Vineries were, I believe, the first examples that were offered to the public. I suppose on any estate where a staff of carpenters is kept they could be manufactured without infringing anyone's patent. It does not require a great amount of skill to make a garden frame, and the most useful of them are, after all, only a handy modified form of the old garden frame. There is, I think, no question that the aid of glass in the shape of cheap portable frames, of various widths and lengths, is calculated to do as much for vegetable culture as it has done in another form, and is still doing, for fruit culture. The cultivator, moreover, who has a supply of those handy frames at this season stands in a far better position than the man who has nothing of the kind, and success is often quite as much a question of means and circumstances as of skill. In addition to the mere protection afforded by these frames, which is very considerable, they will be found very useful for forcing many things. Thus, a trench may be opened the width of a frame—and they may be obtained any width, 2 feet of hot dung and leaves placed in, and about 6 inches of light soil placed on the top, and a miniature hot-bed is formed without much expense, either in labour or materials, that is especially adapted to forwarding salading of all kinds, including Radishes, Lettuce, Mustard and Cress, &c. With a rather greater depth of soil, Potatoes or Cauliflowers may be successfully grown much earlier than they can be without having recourse to more elaborate, and consequently expensive, preparations. Excellent Asparagus might be forced, without disturbing the beds, from this time onwards throughout the spring, by placing a range of these handy light frames on each bed in succession. Some of the earth might be removed from the alleys, and the space filled up with warm dung and leaves, building it up to the top of the frames, matting up the lights, except on sunny days, till the heads were pushing through. In some places it may be advisable to plant two or three beds, especially for this kind of forcing, where the litter would not be objectionable; and, in such a case, if possible, the beds should run east and west; then, if lean-to frames were used, the full benefit would be obtained from the sun's warmth. Where there are the means of bringing forward Tomatoes very early under glass, either in pots or planting them out in a warm light house, if cuttings were not secured in the autumn (which is the best way), seeds may be sown and pushed on near the glass in heat; but, unless for the special object I have named, next month will be quite early enough to sow for general outdoor culture. Wherever there is likely to be a scarcity of either Cauliflower, Cabbage, or Lettuce plants, a small sowing in pans, of each might be made, and the pans placed near the glass, in a temperature of about 50°. So soon as the land is in a workable condition, the warmest border destined for early crops in the open air should be renewed, as much as possible, by adding fresh rich light soil, or thoroughly decayed dung, preparatory to cropping. There is nothing, however, gained by either planting or sowing when the land is not in a fit condition; therefore, however anxious we may be, to be up and doing, it will be better to wait a few days.—E. HOBDAV.

The Flower Garden and Pleasure Grounds.

While the weather remains in its present condition very little can be done in the open air in these departments, further than to furnish plants, of whose hardiness there may be any doubt, the necessary protection in the form of a slight covering of some sort, and mulching around the stem, &c., with dry litter. The present winter is proving itself by no means an ordinary one; on several occasions during the last week of December the temperature fell to within a few degrees of zero, and such depressions are found not unfrequently to prove injurious, and sometimes fatal to species which are generally regarded as quite hardy. Fortunately, however, for bulbs in any degree tender, as well as for Alpine and other herbaceous plants, they have had for some time the advantage of Nature's protection in the form of a few inches of snow, which should not, on any account, be removed. But this protection cannot, of course, extend to trees and evergreen shrubs, whose frozen foliage, &c., is daily, to some extent, thawed by the influence of an hour or two of winter sunshine; and it is to these alternate thawings and freezings that the injury

so frequently inflicted upon evergreens, &c., are to be ascribed. So, if not already done, let all plants occupying prominent positions, or specimens which can ill be spared, of such species as the *Arbutus* or Strawberry tree, *Aucubas* of various sorts, and *Daphnes*, *Desfontainea spinosa*, *Escallonias*, the *Laurus nobilis* or the Sweet Bay, and various kinds of *Yuccas*, and Asiatic species and varieties of the *Rhododendron*, new Coniferous trees of moderate dimensions, &c., be surrounded with a few stakes, on which to support a covering of mats or frigi domo; the latter always proving a very effective protection. While the frost continues so intense as it is at the present time, allow by all means the covering of snow to remain upon the roofs of pits and frames, containing Alpine and other half-hardy plants; but, as soon as a favourable change takes place in the weather, and the snow begins to melt rapidly, let it then be removed, at once, so as to prevent the drip from the melting snow saturating the soil in which the plants are growing. The time is now nearly at hand when the propagation of bedding plants should be commenced; but it may, at the same time, be advisable to defer such work for a time, or until a favourable change in the weather takes place. But, in the meantime, the preparation of materials for the formation of hot-beds, &c., should be at once attended to, such as incorporating tree leaves with stable-yard manure by frequently turning the same.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Orchids

During this month the demand for Orchid flowers, for the decoration of vases, ladies' hair, &c., is unusually great, and, therefore, such choice varieties as *Odontoglossum Bluntii*, *O. pulchellum*, *Cœlogyne cristata*, *Lælia albida*, *L. anceps*, *Angræcum sesquipedale*, *Phalænopsis grandiflora*, *Schilleriana*, and *amabilis*; and *Cattleya Trianae* should be grown in dozens. These are so often imported as to bring them within the reach of almost everybody. *Dendrobium heterocarpum* is one that should have a place in every collection, not on account of the beauty of its flowers so much as for its perfume. *Cattleya maxima* should be more common than it is, and, if grown in the Mexican-house, it is almost certain to do well; it requires little shade during summer, and will produce blooms late in autumn. *Dendrobium chrysanthum* should now be put in baskets or top dressed, as the case may require. It should also be supplied once a week with weak manure-water, and the young growths should be sprinkled on bright days with pure water. This species should be suspended at the warm end of the *Cattleya*-house until it has completed its growth, when it should be placed in a house to ripen, free from shade. Keep plants of *Disa grandiflora* well supplied with water after they have begun to grow; also *Odontoglossum Bluntii*, *O. Pescatori*, *Oncidium macranthum*, and *Masdevallia*, all of which should be well supplied with water, in order to keep the *Sphagnum Moss* in a free-growing state. The latter should be encouraged to cover the surface of the pots. Now is a good time to look over plants and to make a list of such as require re-potting. Great care will now be required in order to keep up a regular temperature, which should be allowed to fall a few degrees rather than rise; less moisture should also be used.—E. CULLEY.

Indoor Fruit Department.

Pot Vines.—Young Vines kept in small pots last summer for cutting back and growing into strong fruiting canes this season, should now receive attention. Cut them over at two eyes from the base, and apply some styptic to the wound, which may bleed when growth begins. When cut and dressed, turn them out of their pots and shake most of the old soil from their roots. Have a corresponding number of 6-inch pots cleaned and drained, and into these pot the roots singly, using a free open pure loam, mixed with a little horse droppings. Give sufficient watering to damp the whole of the soil, and plunge the pots to the rim in a hot-bed where a bottom-heat of 85° exists. They may be plunged as closely together as the pots will stand, and, where a suitable place cannot be obtained for their accommodation in a house, a hot-bed, covered with a frame, will form a suitable place in which to keep them during the first stages of their growth. Another equally successful mode is to cut and dress the Vines, and plunge them, without disturbing the roots, in the soil in which they grew last year, retaining them in this way until they have made a young growth of 2½ or 3 feet in length, when they may be shifted into larger pots without breaking the ball. In this way they grow more freely when young, but they do not root so readily into fresh soil as those which had their roots disentangled. Such Vines are generally grown for starting into growth, with the view of fruiting in October or November, and the earlier they are started the earlier will the fruit be ripened, and thereby have the advantage of a longer rest before the operation is again repeated. Where it is desirable to start pot Vines about the time stated, it is impossible to get them of a satisfactory kind, unless

they have been cut back. Such Vines start into growth more quickly, grow faster, and ripen their wood sooner than one-year-old canes do. Where, however, it is not necessary to start them into growth before January and afterwards, one-year-old canes are as suitable as such as have been cut back, as it does not take so much trouble to attend to the growth of the former as the latter. If plunged in a dry place, a damping overhead with the syringe every afternoon softens the buds and assists them in breaking. Do not water abundantly until they are growing freely, and avoid, by all means, letting any cold draught pass into the early Vineries by having the door open for any length of time. During severe weather, access to such structures should be obtained through an inner door, or where such convenience exists, from a corridor behind them.

Pines.—See that the bottom-heat applied to the second plunged batch of these does not rise above 90° , any indication above which should be the signal to lightly raise the pots as recommended for the first lot. The roots of many early Queen Pines are often rendered useless through non-attendance to this, and consequently the plants refuse to start into fruit until new roots have been made. Valves for the regulation of the bottom-heat should be connected with every Pine bed, so that the heat could be conveniently raised or lowered at pleasure. The humidity kept up about early Queens should be increased in proportion to their growth. A little guano in the evaporating pans also helps to give the foliage a rich deep green tint, and keeps the atmosphere in a healthy condition. Pines are not generally dressed before they are sent to table; but they are much improved in appearance when the decayed blooms attached to the pips are neatly clipped off and the fruit brushed over afterwards, before it is set up for dessert.—J. MUIR.

Indoor Plant Department.

Conservatories.—Use just fire-heat enough to expel damp and frost, and no more; and, in the case of damp, ventilate the house at the same time. Maintain a temperature of 40° at night, with the usual daily rise. Water all evergreen plants moderately, and keep deciduous ones nearly dry. Plants in borders require watering very seldom at this season, there being but little demand upon the roots at this time of year; but pot plants, especially such as are near hot-water pipes, require unremitting attention as regards water, for, although apparently moist on the top, the soil at the bottom of the pots may be dry. Such a condition would be extremely detrimental, as the greatest amount of roots is amongst and over the drainage. Rather than keep the conservatory too warm, in order to forward the plants therein, supply any deficiency there may be in the way of flowers by means of Camellias, Azaleas, Jasminums, Weigelas, Kalmias, Prunuses, Acacias, Dielytras, Lily of the Valley, Dutch and Roman Hyacinths, Tulips, Narcissi, Crocuses, and other plants from the forcing pits. Decaying leaves must be regularly removed, and a rather dry and healthy atmosphere is a good remedy for such an evil, and to effect this, supply artificial heat and plenty of air. Keep Heaths, Epacrises, Chorozemas, Boronias, and Tremandras in the coolest and freest ventilated portion; and forced shrubs and other flowers in the warmest parts. Cut over Chrysanthemums that have done flowering, and keep a pot of each kind in a frame, if sufficient cuttings have not already been obtained. Plant the others in the open border, or, if not wanted out of doors, throw them away. Shift herbaceous Calceolarias and Cinerarias as they require it, and keep them cool and well watered; never permitting a damped or decayed portion of a leaf to remain. Fumigate to destroy aphis, and keep in mind the old maxim, "prevention is better than cure." Keep Mignonette near the glass, and stake and tie it as may be necessary. Have a good succession of it, as well as of Violets, and other plants, in pits. Regularly train Tropæolums, and give them a little manure-water when they have fairly started. Continue to pot off singly, good rooted, early autumn-struck cuttings of Azaleas, Camellias, &c., but if neither time nor space can be spared for shifting them at present, leave them for a time in their cutting pots set on a side-shelf of a close pit or intermediate house. Any Statice becoming too long-stalked should have an incision made on each branch just at the base of the foliated crowns, after which some Moss should be tied round it. The Moss should always be kept damp, and if a little silver sand is mixed with it so much the better, as it helps to encourage root-production. Keep old and young Statice moderately moist and in a minimum temperature of 45° . Pot off cuttings of Libonias and keep them for a short time in a warm pit, and when root action again begins, transfer them to an intermediate house. Divide the rhizomes of the variegated-leaved *Acorus javanicus*, and keep the divided portions for a time in gentle heat. From male *Aucubas* in flower gather the pollen and keep it dry between bits of glass for future use. Start into growth, in a warm pit, tropical *Crinums*. Re-pot and start some *Hæmanthus*es;

they may be placed upon the floor in a warm house or pit, or on a back shelf.

Bedding Plants.—Pelargoniums must still be kept rather dry, with the exception of a few plants of them, which should be placed in an intermediate house and moderately watered, in order to induce them to make young wood for propagating purposes. Keep all the finest-leaved kinds, such as tricolors and bicolors, near the glass, in light airy pits or greenhouses, and give them also sufficient water to prevent them from flagging. Verbenas, Ageratums, Salvias, Tropæolums, and similar plants, should be cleared of all decaying leaves, and dry wood-ashes or sand should be scattered over the surface of the soil in the pots or boxes that contain them. If the stock of them is short, introduce a few plants to a warm house, give them a fair quantity of water, and they will soon produce young wood, which may be made into cuttings. Indeed, from this time till the end of April, Verbenas, Ageratums, &c., may be forced and propagated in large quantities, for the cuttings root readily, and soon furnish tops and side-shoots, which may be used for a similar purpose. Sow some *Lobelia* seeds in heat, and prick off the young seedlings, as soon as they are fit to handle, into pots, pans, or boxes, containing light sandy earth well mixed with sifted leaf soil. By sowing *Lobelias*, pricking them out in time, and pinching them a little before the period for planting-out has arrived, they will bloom early and long. Cuttings of *Lobelias* may also be inserted as soon as convenient. Leave *Gazania*s undisturbed till March, it being then soon enough to propagate them; for early-struck plants become long and weakly before they are planted out, unless a good deal of room and pains can be devoted to them. *Calceolarias* in frames and boxes should be well ventilated in fine weather, and all decaying matter removed from amongst them. Remove the points of any shoots that are growing too rankly, and prepare cold frames for purposes of propagation next month. *Calceolarias* strike as well in cold frames if inserted in early February as they do if inserted in October; but, if the operation be delayed till March, they require a little heat to induce them to root readily. Any kinds of *Dahlias* that are scarce may be started in heat at once, and cuttings of them may be taken off and rooted as soon as they can be obtained; next month, however, or even the 1st of March, is soon enough for starting the general stock. If a good stock of *Caladium esculentum* be required, start some of the rested plants in a brisk bottom-heat, and, when they have begun to grow, remove the top and insert it as a cutting, still retaining the old root-stocks in the plunging material. Before long the latter will push forth a numerous progeny of young shoots, which may be separated individually after they form a leaf or two, and be used as separate plants. Rub over the incision with powdered charcoal, in order to counteract damp, and return the root to the position which it formerly occupied, keeping it there until it has exhausted every effort to produce another offset. Seeds of sub-tropical plants, such as *Solanums*, *Wigandias*, *Ferdinandias*, *Uhdeas*, &c., should be sown in heat as soon as possible, in order to have good strong plants before bedding-out time; and all old plants of these genera wintered in pots should be plunged in bottom-heat, in order to produce young shoots to be used as cuttings. Prune back *Hibiscuses*, *Cassias*, *Fuchsias*, *Abutilons*, and similar plants, so that they may begin to grow slowly and hardily. *Acacia lophantha*, raised from seeds sown now, makes good plants before May for mixing with other plants in small beds. Keep *Centaureas* rather dry than otherwise, in open airy houses or pits near the glass, and remove every particle of damped-off leaves that may be hanging about them, sprinkling powdered charcoal or dry wood ashes about their necks and over the soil. Treat *Echeverias* and other succulents like *Centaureas*.

Salt and Snow.—Mr. Church (see p. 17) and Mr. Mackie advocate the employment of salt whenever, through snow or frost, the roads become dangerous or difficult. The suggestion has evoked considerable opposition in many quarters, and especially from Dr. Alfred Carpenter, of Croydon, who points out that the application of salt to snow will have the effect of producing a very cold mixture, which is likely to penetrate the boots of pedestrians, and produce serious results. To this objection it may be answered that such would be the effect of the admixture of snow and salt were they enclosed in a close vessel, such as a refrigerator; but spread out on the road and pavements the conducting power of the earth will prevent the mixture from falling above one degree lower than that of the surrounding atmosphere. It is a certain fact that if the roads be kept moderately salted, which can be easily done by the admixture of rough salt with water in the ordinary watering carts, and its subsequent distribution over the roads, travelling through the slippery streets will be greatly facilitated, and much of the suffering and damage to horses, which has been observable during the last fortnight will be greatly lessened, if not entirely obviated.

THE BEST OF LAST YEAR'S NEW PLANTS.

THE following were awarded First-class Certificates by the Floral Committee at the Royal Horticultural Society's Meetings in 1874:

<i>Adiantum gracillimum</i>	Williams, May 13.
<i>Agave filifera superba</i>	Croucher, May 13.
<i>Agave micrantha picta</i>	Croucher, May 13.
<i>Alsophila elegantissima</i>	Bull, Feb. 18.
<i>Amaryllis (Hippeastrum) Oriflamme</i>	Williams, April 1.
<i>Amaryllis (Hippeastrum) vittata Harrisoniana</i> (as picturata)	Bull, Feb. 18.
<i>Angræcum citratum</i>	Veitch, Feb. 18.
<i>Anthericum Williamsii</i>	Williams, Nov. 11.
<i>Aquilegia leptoceras lutea</i> = <i>A. chrysantha</i>	Douglas, May 13.
<i>Azalea (mollis) Alphonse Lavalle</i>	Lane, May 13.
<i>Begonia Model</i>	Veitch, Sept. 2.
<i>Begonia Royalty</i>	Chambers, Oct. 7.
<i>Betula alba foliis purpureis</i>	William Paul, July 15.
<i>Boronia megastigma</i>	Veitch, April 1.
<i>Campanula Smithii</i>	W. Smith, July 15.
<i>Cattleya fausta</i>	Veitch, Oct. 7.
<i>Cattleya gigas</i>	Veitch, April 15.
<i>Cattleya Veitchiana</i>	Veitch, March 18.
<i>Cerasus Mahaleb pendula</i>	Paul & Son, Aug. 19.
<i>Ceterach aureum</i>	Williams, April 15.
<i>Cheilanthes Bergiana</i> (see <i>Hypolepis</i>)	
<i>Chrysanthemum (Japanese) Duchess of Edinburgh</i>	Veitch, Nov. 11.
<i>Chrysanthemum Gold Thread</i>	Veitch, Nov. 11.
<i>Chrysanthemum The Cossack</i>	Veitch, Nov. 11.
<i>Chysis Chelsoni</i>	Veitch, March 18.
<i>Cineraria, double-flowered</i>	Haage & Schmidt, May 27.
<i>Clematis Countess of Lovelace</i>	Jackman, April 15.
<i>Clematis Lord Gifford</i>	Noble, April 15.
<i>Clematis Lucie Lemoine</i>	Veitch, March 4.
<i>Clematis Marquis of Salisbury</i>	Jackman, April 15.
<i>Clematis purpurea elegans</i>	Cripps, June 4.
<i>Clematis Robert Hanbury</i>	Jackman, May 13.
<i>Coleus Duchess of Edinburgh</i>	Chitty, June 17.
<i>Cornus alba marginata</i>	Paul & Son, Aug. 19.
<i>Cyclamen Rose Queen</i>	Goddard, April 1.
<i>Cyclamen Royal Purple</i>	Goddard, April 1.
<i>Cypripedium Argus</i>	Veitch, March 18.
<i>Cypripedium Roezlii</i>	Veitch, Jan. 21.
<i>Dahlia Countess of Pembroke</i>	Keynes, Sept. 2.
<i>Dahlia John McPherson</i>	Keynes, Sept. 2.
<i>Dahlia Sarah McMillan</i>	Rawlings, Oct. 7.
<i>Dendrobium Ainsworthii</i>	Mitchell, Feb. 18.
<i>Dendrobium amœnum</i>	Bull, June 4.
<i>Dendrobium erythoxanthum</i>	Denning, Aug. 5.
<i>Echeveria Peacockii</i>	Croucher, July 1.
<i>Epidendrum catillus</i> = <i>E. Imperator</i>	Denning, March 4.
<i>Ficus Parcellii</i>	Veitch, April 15.
<i>Gladiolus Duchess of Edinburgh</i>	Kelway, Sept. 2.
<i>Gladiolus James Kelway</i>	Kelway, Sept. 2.
<i>Gloxinia Queen of England</i>	Gee, June 4.
<i>Gymnogramma triangularis</i>	Williams, May 13.
<i>Hæmanthus, Cooperii</i>	Henderson, May 13.
<i>Hippeastrum picturatum</i> (see <i>Amaryllis</i>)	
<i>Hollyhock Mulberry Gem</i>	Chater, Aug. 19.
<i>Hollyhock Rose Supreme</i>	Chater, Aug. 19.
<i>Hyacinth Anna</i>	Veitch, March 18.
<i>Hyacinth Cavaignac</i>	Veitch, March 18.
<i>Hyacinth Mr. Plimsoll</i>	Veitch, March 18.
<i>Hyacinth Quirine Christine</i>	Cutbush, March 18.
<i>Hyacinth Sir Garnet Wolseley</i>	Veitch, March 18.
<i>Hypolepis Bergiana</i>	Rollisson, May 13.
<i>Iris Kæmpferi Edward George Henderson</i>	Blackwood (as <i>Cheilanthes</i>), Aug. 19.
<i>Ixora Fraseri</i>	Henderson, July 1.
<i>Kniphofia McOwanii</i>	Fraser, July 15.
<i>Lilium speciosum atro-sanguineum rubrum</i>	Green, Oct. 7.
<i>Lilium Washingtonianum purpureum</i>	Wilson, Aug. 5.
<i>Lobelia (bedding) Duchess of Edinburgh</i>	Veitch, June 17.
<i>Lobelia (bedding) magnifica</i>	Lidgard, June 17.
<i>Macrozamia tenuifolia</i> ? (as <i>plumosa</i>)	Pine-apple Nursery Co., July 1.
<i>Mammillaria Roezliana longispina</i>	Bull, June 4.
<i>Metroxylon filare</i>	Croucher, May 13.
<i>Narcissus (Polyanthus) fl.-pl</i>	Bull, Aug. 5.
<i>Nerium Dr. Golfin</i>	Veitch, March 18.
<i>Odontoglossum Alexandræ Rothschildii</i>	Henderson, Sept. 2.
<i>Odontoglossum maxillare</i>	Richards, May 13.
<i>Oeceoclades guineensis</i>	Shields, Sept. 2.
<i>Oncidium fuscum</i>	Bull, Sept. 1.
<i>Pelargonium (double) Emily Laxton</i>	Veitch, April 1.
<i>Pelargonium (double) Jeanne Alegatière</i>	Laxton, June 4.
<i>Pelargonium (golden tricolor) Dr. Masters</i>	Wm. Paul, July 15.
<i>Pelargonium (show) Duchess of Edinburgh</i>	Henderson, July 1.
<i>Pelargonium (zonal) Sir Garnet Wolseley</i>	Braid, May 13.
<i>Pellæa decomposita</i> ?	George, July 15.
	Backhouse, June 4.

<i>Pellæa mucronata</i>	Backhouse, June 4.
<i>Pleocnemia Leuzeana</i>	Bull, Feb. 18.
<i>Polyanthus (bedding) The Bride</i>	Dean, March 18.
<i>Polyanthus (fancy) purpurea</i>	Dean, April 1.
<i>Primrose Splendour</i>	Dean, March 18.
<i>Primrose Violaacea</i>	Dean, Feb. 18.
<i>Primula (sinensis) Prince Arthur</i>	Perkins, Feb. 18.
<i>Puya chilensis</i>	Smith-Dorrien, May 27.
<i>Rapatea pandanoides</i>	Bull, Feb. 18.
<i>Rhododendron Duchess of Edinburgh</i>	Veitch, March 4.
<i>Rhododendron Early Gem</i>	Veitch, March 4.
<i>Rose (H.P.) Duchess of Edinburgh</i>	Bennett, April 1.
<i>Rose (H.P.) Madame Lacharme</i>	Bennett, March 18.
<i>Rose (H.P.) Royal Standard</i>	Turner, July 15.
<i>Rose (H.P.) Sir Garnet Wolseley</i>	Cranston, July 1.
<i>Rose (Tea) Duchess of Edinburgh</i>	Veitch, May 13.
<i>Rose (Tea) Madame François Janin</i>	Bennett, March 18.
<i>Sarracenia Stevensii</i>	Veitch, June 4.
<i>Saxo-Fridericia subcordata</i> (see <i>Rapatea</i>)	
<i>Selaginella lepidophylla</i>	Henderson, Sept. 2.
<i>Silene pendula flore-pleno</i>	Dean, July 1.
<i>Solanum quitense</i>	Veitch, Sept. 2.
<i>Sonerila Hendersoni</i>	Henderson, July 15.
<i>Sonerila Hendersoni argentea</i>	Henderson, July 15.
<i>Tacsonia insignis</i>	Backhouse, June 4.
<i>Toxicophlæa spectabilis</i>	Veitch, Feb. 18.
<i>Vanda limbata</i>	Williams, June 4.
<i>Viola (bedding) White Swan</i>	Dean, May 13.
<i>Vitis heterophylla humulifolia</i>	Woodbridge, Oct. 7.
<i>Zygopetalum Sedenii</i>	Veitch, Aug. 5.

Certificates Awarded at the Chiswick Trials.

<i>Pelargonium Anna Pfitzer</i>	Henderson, Aug. 29.
<i>Pelargonium Bonfire</i>	Henderson, Aug. 29.
<i>Pelargonium Claude de la Meurthe</i>	Henderson, Aug. 29.
<i>Pelargonium Colonel Holden</i>	Pearson, Aug. 29.
<i>Pelargonium Ellie</i>	Miles, Aug. 29.
<i>Pelargonium Little Trot</i>	Davis, Aug. 29.
<i>Pelargonium Master Christine</i>	Veitch, Aug. 29.
<i>Pelargonium Mrs. Halliburton</i>	Kinghorn, Aug. 29.
<i>Pelargonium Mrs. Tate</i>	Pearson, Aug. 29.
<i>Pelargonium Mrs. Turner</i>	Pearson, Aug. 29.
<i>Pelargonium Prince Arthur</i>	Fraser, Aug. 29.
<i>Pelargonium Queen of Beauties</i>	Hodgson, Aug. 29.
<i>Pelargonium Rev. T. F. Fenn</i>	Pearson, Aug. 29.
<i>Pelargonium Richard Dean</i>	Henderson, Aug. 29.
<i>Pelargonium Sparkler</i>	Henderson, Aug. 29.
<i>Tropæolum compactum yellow</i>	Dean, Aug. 29.
<i>Viola Blue Bell</i>	Dean, July 15.
<i>Viola Dicksons' Golden Gem</i>	Dicksons & Co., July 15.
<i>Viola Dicksons' King</i>	Dicksons & Co., July 15.
<i>Viola Dicksons' Queen</i>	Dicksons & Co., July 15.
<i>Viola Imperial Blue Perfection</i>	Dean, July 15.
<i>Viola Lily White Tom Thumb</i>	Dean, July 15.
<i>Viola Miss Maitland</i>	Milligan & Kerr, July 15.
<i>Viola Mulberry</i>	Dean, July 15.
<i>Viola The Tory</i>	Dicksons & Co., July 15.
<i>Viola Tyrian Prince</i>	Dean, July 15.

Rats and Cantharikopho.—I beg to inform Mr. Balderstone that, my cottage having been infested with rats for some time, I was induced to try a box of Cantharikopho, procured direct from Messrs. Rollisson, and, to my satisfaction, I have not seen a rat or any indication of the presence of one since. With regard to mice, I used it in my potting-shed, which was over-run with them, and also on cockroaches and crickets, and I have found it in all cases efficacious, except in that of woodlice, which I find will not touch it until it has been exposed to the atmosphere for some ten days, when they will eat it, but of course with impunity, as its destructive properties are then gone.—A. H. MAY, *Wimbledon Park*.—Captain Crawley, writing to Messrs. Rollisson from the Temple Club, Arundel Street, Strand, says that he has tried the Cantharikopho, and has found it to answer admirably. Kitchens, stables, and cellars have all been cleared of mice, cockroaches, &c., by it, and he asserts that it is a most effectual and fatal, though, apparently, an enticing meal.

Tan for Mulching.—There is much difference of opinion as to the value of tan as a mulching material. A recent writer in the *Revue Horticole* cites several instances in which its effects were disastrous upon fruits and vegetables. Several market gardeners near Paris lost all their winter Lettuce by covering the beds with tan. Any ill results must be due to the fact that the bark was not thoroughly exhausted. When the soluble matter is all extracted from it, the effect of the tan can only be a mechanical one. Where there are such different experiences, it will be safe to expose the tan to the action of rains for some months before using it.

WINDOW GARDENS.

MANY and varied have been the contrivances invented to afford facilities to those dwellers in town who indulge outside of a window in the pursuit of horticulture "under difficulties." As a rule, all those inventions, while they may answer the purpose in a horticultural point of view, are anything but ornamental in an artistic sense. A correspondent of our excellent contemporary, the *Building News*, appears to have fallen on a plan to unite use and ornament. The very ingenious mode in which he does so will be best seen and understood by giving his letter and reproducing the illustration, for which we are indebted to the same source:—"External window gardens are now so common in England that it is time architects incorporated them in their designs for villas and cottages. At present they disfigure rather than improve the appearance of houses. If we wander through Belgravia or any modern locality, we shall find at least half the dwellings with windows blocked up by rude unsightly temporary boxes, each vying with the other for unsightliness and for shutting out the daylight. We find that the builder has gone to the expense of glazing the windows with plate glass, about a fourth of which is rendered useless by the tenant's questionable adornments to them. Provision for window gardens is, therefore, a want that should be provided by the builder. The want has been partially met by the balcony or projecting shelf-like sill, but the same rude box is placed upon them to hide the lower part of the glass and obstruct the light.

An improved Window-box.

There are various ways in which the window garden may be architecturally treated, but a hint may be gleaned from the accompanying sketch, of which fig. A shows elevation of part of the front wall and window; fig. B a section of the window and box for earth; and fig. C a plan of same. It will be seen that the ordinary window sill is entirely abandoned, and a box substituted in its place, running under the woodwork of the window till it meets the internal plastering, or what joiners call the window back. Thereby some of the heat of the room is imparted to the flowers, and when the fire-place is situated near the window the heat would assist to make a miniature conservatory."

HAWTHORNS.

WITH one or two exceptions, these are deciduous, ranging in height from about 10 to 30 feet. They have a wide geographical distribution over Europe, Asia, and both Continents of America, and are nearly all hardy enough for open-air cultivation in Britain. A large proportion of the species and varieties are valuable for the ornamentation of parks, margins of woods, and shrubberies, where, from their picturesque outlines, elegant foliage, and the profusion of their showy blossoms, followed, in most cases, by brilliant and conspicuous fruit, they have a peculiarly striking effect, and are justly regarded as worthy of a prominent place in the choicest collections of ornamental trees and shrubs. Many of the sorts, and notably the common Hawthorn with its varieties, are admirably adapted for planting in town gardens and squares, where they grow vigorously, and seldom fail to flower, notwithstanding the dust and smoke, so injurious to most forms of tree life. All the species are found to succeed best in rich, but light, soil, with the ground either

naturally dry or sufficiently drained to prevent any accumulation of water at the roots. They flower and fruit most freely when planted in open sunny situations. In planting, enough of space should always be allowed for the free spread of their branches without coming in contact with neighbouring trees. In making a small selection from a genus containing some fifty or sixty species and varieties, many that are really desirable must necessarily be omitted; the following, however, are among the most popular, and well worth the attention of intending planters, being quite hardy, very distinct, and at the same time highly ornamental.

C. Oxyacantha (the common Hawthorn).—This, the type of the genus, is indigenous to most countries in Europe, including our own, where it has been grown as a decorative tree "time out of mind"—the pride of the humble cottage-garden and the village-green,

With seats beneath its shade
For talking age, and whispering lovers made;

and not less so in the noble parks and well-kept pleasure-grounds of the rich, rivalling all the other trees in beauty when in blossom, while its ample spreading head and gracefully bending branches render it at all times a pleasing and interesting feature in the landscape. Its importance as a hedge-plant, either by itself, or mixed with Beech or Privet, is well known; and it need scarcely be said that, if kept properly trimmed, no plant makes such a close, strong, and durable fence. The snow-white sweetly-fragrant flowers are produced in great abundance in May or June, according to the season, followed generally by a crop of red fruit, usually ripe in September. The leaves are obovate, wedge-shaped, sometimes nearly entire, but more frequently deeply cut into lobes; in spring they are of a light green, changing in summer to a darker tint. There are a great number of fine varieties of this species, more or less distinct and handsome. The following are among the most useful for decorative planting:—*Variegata aurea* and *v. argentea*, with gold and silver variegations, are interesting as varieties, though by no means to be classed among the showiest of variegated trees; *fructo-lutea* differs from the parent in having yellow fruit, and is very ornamental in autumn and early winter; *Reginæ pendula* is a fine weeping form, quite distinct from the species—the original tree, known as Queen Mary's Thorn, stood in a garden of the Canongate of Edinburgh which belonged to the Regent Murray, but was cut down some years ago; *spinosissima* is remarkable for the great number of stiff sharp spines with which the branches are thickly studded, and which have a curious effect when the leaves are off; *coccinea* is the well-known scarlet Thorn, a universal favourite, which cannot be too extensively planted; *laciniata* differs from the parent in its leaves being deeply cut into numerous segments; *præcox*, the Glastonbury Thorn, is interesting from producing its leaves and flowers much earlier in the season than either the species or any of the other varieties. There are also the following double-flowered sorts, which are truly beautiful when in bloom, and cannot be too highly recommended for planting in shrubberies among the larger-growing evergreens, or for single specimens either in parks or lawns:—*Albo pleno*, double white; *rosea plena*, double pink; and *coccinea plena nova*, the last known as Paul's Double Scarlet Thorn, a variety of recent introduction to our gardens, but already widely distributed, and undoubtedly one of the most valuable acquisitions to the list of hardy flowering trees, flowering, like the other double sorts, when only a few feet high, and quite showy enough for the finest flower garden. Forced in a gentle heat, it is a grand plant for the conservatory in early spring.

C. Aronia (the Aronian Thorn).—This species, indigenous to Greece, as well as several other countries in the south-east of Europe, and introduced in 1810, is a distinct-looking handsome tree of about 25 feet in height. It has a very densely branched, rather erect habit of growth; the leaves are wedge-shaped at the base, deeply lobed, and toothed at the edges; the young shoots and under surface of the leaves are slightly pubescent. The flowers, which generally expand in June, are white, followed by large yellow fruit ripe in September, and not only very ornamental, but eatable—making excellent tarts either alone or along with Apples. It is an interesting park or avenue tree.

C. coccinea (the Scarlet-fruited Thorn), indigenous to North America, from Canada to Carolina, and introduced into Britain in 1683, is a bushy spreading tree of from 25 to 30 feet in height. The leaves are of an ovate-cordate form, serrated, much larger than those of the common Hawthorn, and of a warm green colour, changing at the fall to a bright yellowish-red. The flowers are large and showy, pure white, and expand in the beginning of June. The fruit is of a brilliant scarlet colour, very palatable, and ripe about the end of September. It is a distinct and very ornamental park specimen-tree.

C. Crus-galli (the Cockspur Thorn).—Another North American species, with a similar distribution to the preceding. It was first

introduced about 1791, and in this country grows to heights of from 15 to 20 feet. The specific name was given in allusion to the long bent spines with which the branches are armed, giving the tree a singular appearance in winter. The leaves are of an obovate form, slightly serrated at the edges, of a smooth shiny green colour, and are remarkable for remaining on the tree longer than those of the other deciduous species. The flowers are white, and usually in perfection in June. The fruit is bright scarlet, and ripe about October. As a park specimen-tree it is very ornamental, and, though quite hardy, succeeds best in a sheltered situation. Of several interesting varieties in cultivation the most distinct is *salicifolia*—a curious, broad, horizontal branched tree, with oblong nearly lanceolate leaves, suggestive of those of some of the Willows: it forms a most effective contrast in mixed collections of decorative trees.

C. cordata (the Heart-shaped-leaved Thorn), a native of North America, found over a vast tract of country in Canada and the United States, and growing to heights of from 20 to 30 feet. The leaves are large, cordate-ovate, very abundant, and of a shiny deep-green colour. The flowers are white, and though individually small, are produced in large terminal corymbs, and have a pretty effect in May or June, when in perfection. The fruit is scarlet, but small and inconspicuous, and ripe about October. When planted in a dry sheltered situation, this forms a neat specimen-tree, with a close bushy habit of growth, well suited for planting in a choice collection.

C. macrantha (the Long-spined Thorn), found wild in great abundance in the Northern States of North America, from whence it was first introduced in 1819. It is a broad-spreading tree of about 25 feet in height, and remarkable for its numerous long sharp spines. The leaves are large, ovate-oblong, serrated, and of a bright green colour. The flowers are white, and usually in perfection in June. The fruit is scarlet, very small, but generally produced abundantly; ripe about September. As a park tree, it is conspicuous and pleasing, and ought to be more frequently planted. It thrives best in a moderately sheltered situation, and in dry porous soil.

C. tanacetifolia (the Tansy-leaved Thorn), indigenous to Greece and adjoining countries, and introduced in 1789, is an upright-growing tree of about 30 feet in height. The leaves are somewhat larger than those of the common Hawthorn; deeply divided into irregular segments, and covered with a minute down. The flowers are white, and expanded in May or June. The fruit is round, large, eatable, and of a golden-yellow colour. This species is an old favourite in our parks and pleasure grounds, growing, as it does, almost everywhere, with great vigour, and forming a remarkably attractive specimen, its peculiar grey-coloured foliage contrasting well with the darker shades of most other trees. Of several distinct varieties the most interesting is *Leeana*, which differs from the parent chiefly in its more robust, closer, more fastigate habit of growth, and in its larger, less divided leaves; it is a handsome and most desirable ornamental tree.

C. punctata (the Dotted-fruited Thorn), a North American species, found over a large tract of country, particularly in Virginia and Carolina, is a small bushy spreading tree of about 25 feet in height, introduced in 1746. The leaves are obovate, wedge-shaped, acutely serrated, and of a bright shining green colour. The flowers are white, expanding in June; the fruit is bright scarlet, dotted or speckled. The following varieties are distinct, and worthy of special notice:—*rubra*, with fruit of a darker red, and a habit of growth more robust than the parent; *stricta*, differing only in its fastigate habit; *fructo-aurea*, with the upright habit of the preceding, but with golden-yellow fruit. All the sorts are beautiful trees, and well deserving of a place in the park or ornamental plantation.

C. orientalis (the Eastern Thorn), found wild in the Crimea and northern borders of the Black Sea, is a small bushy tree of about 20 feet in height, introduced in 1810. The leaves are deeply lobed, downy on the under side. The flowers are white, expanding in June. The fruit is very large, eatable, of a deep purplish-red colour, and ripe about September. It is a distinct and neat-growing lawn or shrubby tree, and ought to be better known.

C. Douglasii (Douglas's Thorn), indigenous to North-west America, from whence it was first sent home in 1827, is a strong-growing shrub or small tree of from 10 to 15 feet in height. The leaves are obovate, sometimes ovate-serrated, dark shining green, changing, as they decay, to a dark red. The flowers are white, and generally expand in June. The fruit is small, but produced in great abundance, of a deep red, almost purple colour, and ripe about September. It is a very distinct and interesting plant for a mixed shrubbery, most effective either when in bloom or when laden with its rich-coloured fruit, which it retains till late in the season.

C. Pyracantha (the Pyracantha).—This is an evergreen species indigenous to the south of Europe, where it is found as a spreading bush, with long slender branches, rarely rising higher than about

10 feet; it has been in cultivation here since 1629. The leaves are entire, crennated, and of an ovate-lanceolate form. The flowers are white, produced in large corymbs, and usually in perfection in May. The fruit, which it rarely fails to produce in great abundance, is brilliant scarlet, ripe about September, and remaining on the plant during the greater part of the winter, and even sometimes till the spring. The yellow-fruited variety, *fructo-lutea*, though not so striking, is, nevertheless, a fine companion plant to the species. Though sometimes grown as a shrub in the open border, or grafted as a standard on the common Hawthorn, and as such very ornamental, this species is at once best known and most useful as a wall or trellis plant, for either of which purposes, particularly the former, it has few rivals. Whether we take into account freeness of growth, elegance of foliage, or the striking beauty of either flowers or fruit, it can scarcely be too strongly recommended where a thoroughly hardy plant is wanted for the decoration of a villa dwelling, or a flower-garden wall. It delights in a dry but rich soil, and thrives all the better for an occasional supply of well-rotted manure.—*The Gardener*.

PERSONAL.

MESSRS. CARTER'S challenge cup will again be offered for competition at the provincial exhibition of the Royal Horticultural Society, should one be held this year, and along with it £10 10s. as first prize; the second, third, and fourth prizes being of the value of £7 7s., £5 5s., and £3 3s. respectively. Other prizes for vegetables, of considerable value, are also offered by this firm.—MM. Nardy & Co. have established at Salvadour, near Hyères, a nursery which, from the reputation of its founder and its climatic advantages, will probably prove of importance in the introduction of new plants. MM. Nardy liberally offer to botanists, directors of botanic gardens, horticultural societies, and the like, the opportunity of using their grounds as trial grounds for testing the hardiness and applicability of new plants, and promise to report progress regularly to those interested.—The King of Italy has conferred the honour of Commander of the Order of the Crown of Italy on MM. Linden and Ronnberg, and that of Chevalier on MM. Bernard, Dallière, Kegeljan, and Morren. The immediate occasion of these honours was the International Horticultural Exhibition at Florence.—Mr. J. C. Marsh, for some years gardener to J. O. Bacchus, Esq., of Leamington, and well known as a successful exhibitor, is said to have perished in the ill-fated ship, *Cospatrick*.—On New Year's Eve Messrs. Cranston and Mayo treated the workpeople employed in their nursery at King's Acre, Hereford, to a supper, concert and ball.

NOTES AND QUESTIONS.

[THE following notes and questions came to hand, or were answered too late for insertion in their several departments.]

Draining Lawns or Cricket Grounds.—Would any of the readers of THE GARDEN favour us with their experience as to the proper depth of drains for lawns or cricket grounds? The sub-soil in our case is peat.—W. J., *Lancashire*.

The Belgian Mole Trap.—Have any of your readers used this trap, or can they inform me if it is in any way superior to any of the mole traps generally in use in this country.—ENQUIRER.

Some Good Wall Roses: L. H. Jules Margottin, Céline Forestier, Fellerberg, Lamarque, Ophir, Gloire de Dijon, Climbing Devoniensis, Red Rover and Climbing Victor Verdier.

Hardy Amaryllids: W. T. S. Amaryllis Belladonna is a hardy bulb, which does admirably when planted rather deeply in good soil at the foot of a south wall. Mr. Barr informs us that it flowers perfectly with him in the open field. The Crinum capense is also perfectly hardy.

The Olive.—Can any reader of THE GARDEN supplement the information given at p. 13, with further facts relative to the soil best adapted to the cultivation of the Olive, whether the climate is damp or dry, the locality hilly or sheltered, what kind of manure (if any) is required for a successful crop of fruit? how propagated, and at what age the tree begins to bear?—G. A. H.

Conifers for a Damp Situation.—I should be much obliged for information about the kinds of Conifers best suited for a swamp near the waterside. Am I right in supposing that *Juniperus Virginiana*, *Taxodium distichum*, and *Thuja occidentalis* would find themselves at home in such a situation? Information from anyone who has observed these or other Conifers in their native swamps would much oblige.—SALMONICRIPS.

Furnishing a South-west Wall with Fruit Trees.—I am much interested just now in endeavouring to ascertain the best way of furnishing a south-west wall with Pear trees. My idea was to have fan-trained trees, at about 12 feet apart, as permanent trees, putting some five-tined between, to bear for a few years, and then be removed. I went expressly to Sawbridgeworth to purchase these trees, but Mr. Rivers persuaded me to have horizontal train instead of fan-shaped. In planting these latter I could not bring the side shoots opposite the wires, and, altogether, the arrangement was most unsightly. I, therefore, determined to put in only the five-tined trees, 5 feet 8 inches apart. With this, however, I am not quite satisfied, as the space nearly 4 feet between the trees is entirely wasted. I am aware that they may be planted a little closer, but they would, to my mind, never look well. W. B. S., therefore, who wrote last week in THE GARDEN on this subject, states where Verrier Palmette trees can be obtained; also, if five-tined trees would do to put between instead of flat standards? The wall is nearly 100 feet length, 9 feet high and wired.—B. Hook, *the Cottage, Bradfield, Berks*.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

SEEDS AND SEED CROPS.

Most gardeners select their own seeds, stating both variety and quantity required, and, whether the order be large or small, this is the best course to follow. Of late years it has become the practice with some seedsmen to offer certain quantities of seeds—to crop gardens of given extent—at what may happen to be tempting prices, but only the inexperienced will be led away by such offers. Hardly two kitchen gardens are cropped alike, as regards quantities and varieties. Here a certain vegetable is in constant demand; there it is, perhaps, not wanted at all. In one place certain varieties are found to succeed, and in another they are a comparative failure; and this applies to the villa garden just as much as to the nobleman's 6-acre enclosure. How then can the seedsman anticipate your wants? He will be able, no doubt, to dispose of his stock in a satisfactory manner to himself, but the customer will have to pay for many things he does not want. Let everyone therefore order what he requires, and he ought to get his own selection as cheap, proportionately, as the seedsmen do. I may state here that some if not all the so-called "collections" of seeds advertised to crop kitchen gardens of different dimensions, are neither suitable in kind, nor sufficient in quantity, for the purpose. Economical as we can be, to the extent of saving all old seeds to mix with the new, I find a kitchen garden of 4 acres cannot be furnished at anything like the price of the seedman's "collection," after making a slight allowance for bad seeds, birds, and vermin. I see some respectable firms repudiate the practice of selecting for their customers, realising fully that they cannot do so with satisfaction to either party, and it would be well if others were to follow their example. Possibly some economy might be effected if every seed was sure to vegetate; but, as such a thing cannot be guaranteed, the gardener has to sow much more thickly than is absolutely necessary to ensure a crop; and, in estimating how much seed is required for an acre, such contingencies must be taken into account. Of course the seedsman is not always to blame for failure; sometimes the customer's want of care in storing is the cause. Still, we have often seen signal failures with such things as Peas, Carrots, Onions, &c., from seed sown when it arrived from the shop, and said to have been proved before sending out. To prevent disappointment from any cause as much as possible, the best plan is to deal only with respectable firms, who are careful to meet their customers' wants. To retain the latent vitality of seeds as long as possible, they must be preserved from the exciting influences of heat and moisture. It is desirable that they should never be subjected to a higher or lower temperature than 40°, but it is absolutely essential that they should be kept dry. The moment a seed comes in contact with moisture it begins to grow if the temperature is high enough, and if not then placed in circumstances congenial to its development, as in the soil, it will of course perish. Without moisture in sufficient quantity to excite growth, however, seeds may be subjected to a much higher temperature than 40° without any immediate bad effects, though a high and dry temperature impairs their vitality; hence it is that seeds that have been kept for several years do not germinate so vigorously, though they are generally more fruitful. For this reason, old Melon seeds are preferred to new, as they do not run so much to vine; and when new seeds only of a variety are to be had, some gardeners carry them in their pocket, or keep them in a warm room for a while to effect the same end. On the other hand, it is equally necessary to keep seeds dry under a low temperature—42° being the growing point, or lowest temperature at which seeds will germinate as a rule; exposure to damp below this figure promotes decay, especially in the more tender seeds. Thus, Kidney Beans, for instance, may be subjected for a time to a temperature of 35° without much injury if they are kept

dry, but it is a well-known fact that they will perish almost rather than germinate in soil below a temperature of 45°; hence early crops are generally uncertain. Under these circumstances, and seeing that collections of seeds, even for a large garden, are not very bulky, the best plan is to keep them in a portable cupboard, which can be moved when required and may be found needful in very warm or very cold weather. Where seed saving in quantity is an object other arrangements must, of course, be made, but having pointed out the essentials it is only needful in such cases to adapt them to circumstances. The seed press should be methodically pigeon-holed, according to the quantities each space has to hold, and these should be labelled to prevent confusion. These remarks being intended for seed sowers rather than seed growers, I need say nothing about seeds-bags or packets, further than that the seeds should be stored in the brown paper parcels in which they arrive, and be taken out when wanted. Many failures date from the period of sowing, for which, not unfrequently, the seedsman is unjustly blamed. To prevent disappointment it is a wise plan to prove seeds before sowing, especially vegetable or flower seeds, of which large breadths have to be sown. To do this it is only necessary to sow a few seeds of each variety in a small pot, in light soil, and introduce them to a moist temperature of 90° or a 100°, taking care to water them about a day after sowing. If they possess any vitality they will soon show it under such a stimulus, and the number of seeds of each kind that germinate will be a guide for future operations. In sowing small seeds everything depends upon the care and intelligence of the operator, and in outdoor crops, such as are committed to the ground at once, much importance attaches to the condition of the soil, and the time of sowing different crops. With small seeds, such as the *Calceolaria*, *Primula*, *Lobelia*, *Celery*, herbs, &c., failure often results from using an unsuitable soil, deep or thick sowing, and careless watering. With regard to soil, though many plants will thrive well in a strong loam after they are established, no seeds of any kind will germinate readily in such a medium. For all small seeds the soil should be light, fine, and rich—light and open so as not to exclude the air, so finely divided and loose as not to obstruct the young stem in its ascent to the surface of the soil, and rich in order to promote a quick and vigorous germination, that the seedlings may escape the many destructive insects and grubs which are continually on the alert to prey upon them at this stage, and also to enable them to resist any external influences that have a tendency to lower their vitality. A poor soil is the worst of all for a seedbed, and farmers and gardeners know from experience that a vigorous start is the surest guarantee of a crop with many things, such as Turnips and Carrots, that so often fall a prey to vermin, if from any cause germination is slow or retarded. Deep sowing is a frequent source of failure. It is a pretty well known fact, that seeds buried beyond a certain depth will not germinate at all, though they do not lose their vitality; but many persons, whose duty it is to sow seeds frequently, are hardly aware how thin a layer of soil is sufficient to prevent germination altogether, or at least to impair the vigour of the plants so much that when they do come up they will hardly recover. Thus small seeds like the *Calceolaria* will barely vegetate under half an inch of soil, as we have proved; that depth is more than sufficient for such hardy plants as Cabbage and Turnips, especially if the soil be heavy and apt to cake. Peas and Seakale are in no way benefited by being covered deeper than an inch or an inch and a half. Deep sowing gives a plant no better hold of the ground than if it was left to vegetate on the surface; it is thin sowing, or room, that makes a stable plant. In soils for all small seeds, sand is a highly useful ingredient as a disintegrating agent; while decayed leaf soil, or humus, finely sifted, will give lightness, and, in general, sufficient richness for a seed bed. The surface of the soil in seed pans or boxes should be made quite even with a piece of wood or slate, and small seeds should be barely covered. It should always be borne in mind that sufficient soil to ensure a moderate and uniform degree of moisture about the seed, and a ready access to food for the young roots, is all that is required; these secured, seeds do not appear to be much affected by the

presence of light or by its absence. Thick sowing is a mistake no good gardener will commit. When it is necessary to sow plentifully to ensure a crop, the seeds should by no means touch each other, as, under such circumstances, decay and rottenness are apt to be produced, particularly if the seed be old. Outdoor crops are not likely to be injured by artificial watering, but a careless man will often ruin a seed pan with the watering pot, notwithstanding all previous care in sowing. The finest rose should be used for watering purposes, and the soil should only be damped, repeating the operation again and again till the watering is effected; never float the surface, and never direct the full force of the water upon it, or the seed will be washed on one side, or out of the pan altogether. As regards outdoor crops, much depends upon the weather in the effect it has upon the soil. Seeds sown in a wet soil never come away freely; it is better to wait till the latest moment than sow under such conditions. Those crops do best, without doubt, which, favoured by suitable weather, come away and grow uninterruptedly from the seedling state. Still, though I am not tied to dates in sowing crops, as old gardeners used to be, there is a period in spring beyond which sowing cannot be delayed without risk. For instance, Onions should be sown some time in March; if delayed much past the beginning of April, the crop will not be a good one. Late Wrinkled Marrow Peas do little good, in late localities, at least, if sown before the first of April. Neither is time gained by sowing Seakale before this date. Nearly ninety per cent. of Turnips sown in January go to seed—often the entire crop—and they are not earlier than those sown in March. The same may be said of Peas, unless in exceptional seasons. Cauli-flowers sown in heat in January, and pushed on as early autumn-sown plants generally are, come into use just as soon. Beet sown in March, or earlier than the middle of April or beginning of May, will nearly all go to seed. Carrots are much better out of the ground till the soil is warm enough to start them into vitality about April. For Parsley the ground should be rich and deep. It should be sown as the ground is dug and covered with light and very rich soil, in order to coax it into early leaf, and it should be early thinned out if it has to afford a winter supply. Broccoli, sown in February, and another lot in March, will generally all come in at the same time, but there is a much better chance of a succession if the last sowing be delayed till the middle of April or till May. French Beans, sown before the temperature of the ground reaches 45°, will hardly move perceptibly, and will rot in the ground. Celery sown in March or April, and planted about the middle of June, is early enough to ensure good useful heads in August and September, and planting may be continued till August. It is an excellent plan to steep all hard-cased seeds, such as Peas, Seakale, Beetroot, &c., in tepid water for twenty-four hours before sowing, especially if this has been delayed, in order to promote germination, but seeds sown in good time do not need steeping, for, though they may be got through the ground sooner, their after progress being dependent upon the weather, they gain nothing in time in the end.

J. S. W.

The Best Twenty-four Hollyhocks.—The following, says Mr. Dean, is a list of the finest flowers in cultivation:—Alba superba, pure white; Black Gem, glossy blackish-maroon; Competitor, deep rich purple; Eclipse, bright rosy-red; Edward Speed, French white, suffused with deep purple; Eleanor, soft pale rose, a greatly improved Willingham Defiance; Emperor, crimson-maroon; Exultium, rich shining maroon; Fire King, bright glowing reddish-crimson; Golden Drop, perhaps the deepest and brightest yellow in cultivation; Jessie Dean, clear apricot sometimes tinted with salmon; Joshua Clarke, brilliant cherry; Junia, pale primrose, suffused and stained with purple; Leviathan, bright reddish-rose, very fine; Lord Napier, deep glowing scarlet-crimson; Midnight, deep glossy maroon; Mrs. W. Chater, pale flesh, the colour deeper at the base; Nonpareil, rich dark purplish-maroon; President, yellowish-buff, heavily suffused and tinted with rose; Rose d'Amour, beautiful rosy-peach; Ruby Queen, deep shining ruby; Walden King, bright scarlet; Walden Queen, beautiful soft delicate flesh; and Walden Primrose, clear pale primrose. It may be added that of this list all are seedlings raised by Mr. Chater, with the exception of two raised by Lord Hawke.—“Florist.”

NOTES OF THE WEEK.

— THE engraving of *Lapageria rosea*, growing in the open air in the Lucombe Nurseries, Exeter, is an exact reproduction from a photograph, and well shows what may be done with this noble climbing plant in the south of England.

— A NEW hybrid Pitcher plant was exhibited by Messrs. Veitch at the last meeting of the Royal Horticultural Society, and received a first-class certificate. It is a seedling, raised between the well-known *N. Rafflesiana*, and an unnamed species with small spotted pitchers. In shape and colour the Pitchers resemble those of the first-named parent, and in size are equal to those of *N. hybrida maculata*.

— MR. COX exhibited at South Kensington on Wednesday last a new Apple, a seedling from the well-known Golden Knob, and one which is likely to prove a valuable addition to late-keeping dessert sorts. It is named Redleaf Russet, and possesses a very agreeable flavour, being both brisk and juicy.

— MESSRS. SUTTON, of Reading, have published a “Miniature Spring Catalogue,” pocket size and weighing only 2 ounces. It is a reproduction of their large “Spring Catalogue and Amateur’s Guide,” including the cuts and ornamental borders, the type used being very small but clear. It is a curiosity in its way.

— THE assistant-secretary of the Meteorological Society, Mr. William Marriott, has published a very useful table to facilitate the determination of the dew-point from indications of the wet and dry thermometers, which allows anyone to obtain the dew-point at inspection without going through several calculations.

— RHODODENDRON ARGENTEUM, one of the very best of all the white-flowered kinds, is now in flower. A fine truss of it, fully 6 inches across, was exhibited at the Royal Horticultural Society’s meeting, on Wednesday last, under the name of *R. niveum*. It appears to be a variable plant.

— WE have received specimens of Mr. Ware’s bedding Pansy called Modesty, a variety distinguished from all others of its kind by the abundant way in which it blooms in winter, there being at present thousands of flowers on a bed of it in his nursery, at Tottenham. In colour it is purplish-lilac, with a dark eye set in white.

— MR. CHARLES DARWIN’S new work on “Insectivorous and Climbing Plants” is in the press and will be shortly published. The following are the contents:—Part 1, On the sensitiveness of the leaves of *Drosera*, *Dionaea*, *Pinguicula*, &c., to certain stimulants; and on their power of digesting and absorbing certain animal matter. Part 2, On the habits and movements of climbing plants. The book will be issued by Mr. John Murray.

— MR. PARKER and Mr. Barr have both sent us flowers of *Crocus Imperati*, one of the most beautiful of all Crocuses, and one doubly valuable inasmuch as it is a winter-blooming species. Its sepals are yellow on the outside, streaked with very dark purple, while the insides of the sepals and the whole of the petals are of a soft lilac-purple, faintly streaked with deeper-tinted veins. It is a plant which deserves a foremost position in the collection of all who appreciate hardy early-flowering bulbs.

— A VIGOROUS plant of *Eulophia guineensis* is now bearing two fine spikes upwards of 2 feet in length in the Orchid-house at Kew. In form the individual flowers remind one of those of *Galeandra Devoniana*, except that they are a little smaller in size. The segments of the perianth are greenish, shaded with brown, the conspicuous part of the flower being the rich rosy-lilac long-spurred lips. If we except the brilliantly-coloured large-flowered *Disa*, this is one of the most effective of all terrestrial Orchids, and a worthy companion to the rich golden-flowered *Cyrtopogon flava*.

— NEOTTIA MACULATA is now flowering in the cool Orchid-house at Kew, and, although like its congener, *N. speciosa*, an old inmate of our gardens, it nevertheless deserves mention as a very distinct and beautiful plant. The rich velvety deep green leaves are blotched with lighter green, and the reddish-crimson flower-buds and bracts form a brilliant contrast, and prove attractive for several weeks. A large pan of this plant, if well grown, would form a very distinct and beautiful addition to the few crimson-flowered Orchids which flower at this season.

— THE annual meeting of the Gardeners’ Royal Benevolent Institution took place on the 14th inst. The report, which was read, showed that there are seventy-two pensioners on the charity, receiving £930 annually; that the income amounts to £1,747, and that there is now an invested capital of £10,400 in Consols. After the close of the meeting a testimonial was presented to Mr. Cutler, after thirty-two years’ service as secretary to the institution. It consisted of a very handsome one, the sum realised being £250. It was a silver tea and coffee service with salver, table forks and spoons, and a massive gold watch-chain; a valuable diamond half-hoop ring and a gold watch-chain were also presented to Mrs. Cutler.

THE LUCOMBE NURSERIES, EXETER.

In a nursery that has been in existence over a century-and-a-half, we naturally expect to find many things rarely found in establishments of more recent origin, and in this instance we were not disappointed. Apart from the fine climatic position occupied by this well-known Devonshire nursery, it has been managed, from its first commencement until the present time, by proprietors who have taken a more than ordinary interest in all that concerns horticulture, apart from its pursuit as a commercial undertaking. With the taste and skill displayed by the late Mr. Pince in ornamental ground-work and planting most of us are familiar, and the present proprietor, Dr. Woodman, an enthusiastic horticulturist like his late relative Mr. Pince, has already attained considerable reputation as a landscape gardener. The outdoor department consists of nearly a hundred acres, covered with ornamental forest trees, shrubs, Conifers, and fruit trees in every stage of development. About fifty acres constitute what may be called the home nursery, and another fifty occupy a sloping hill-side at Exminster, about three miles off, the

beauty, as they advance in age. Over the late Mr. Pince's tomb is a costly monument, but a still handsomer one to his memory is to be found in the many grand trees which he here fostered and loved during a long and useful life. A pair of Wellingtonias are about 40 feet in height, well-furnished and perfect to the very base. Some idea of the character of these importations from the West may be gathered from the fact that their trunks, at a foot above the ground level measure fully $4\frac{1}{2}$ feet in diameter, or nearly 14 feet in circumference. One of the most perfect Araucarias we ever saw, not even excepting the large one at Dropmore is here branched to the base. It is about 30 or 35 feet in height, and promises to make one of the finest trees in the country. The tawny gravelly soil round Exeter seems to suit this tree admirably, for we noticed many of the specimens which had accidentally lost their lowest branches breaking out into growth again within a foot of the ground level. Here is also one of the oldest specimens of *Cephalotaxus Fortunei* in England. It is 8 to 10 feet high, and was given to Mr. Pince by Mr. Fortune himself. *Thuja gigantea* is here fully 20 feet

Lapageria rosea on an open wall in the Lucombe Nursery, Exeter.

latter being principally devoted to the more common kinds of Conifers, such as Larch and Spruce, and to hardy evergreen and deciduous shrubs. The late Mr. Pince was a great admirer of fine trees, and the chief adornments of the home nursery consist of splendid specimens of Oaks, Wellingtonias, Cupressus, Araucarias, Piceas, and Thujas; and it also contains a very complete collection of green and golden Yews. At the principal entrance to the nursery is a splendid specimen of the Lucombe Oak (*Quercus Cerris* var. *Lucombiana crispa*), having a massive trunk, about 9 feet in circumference, which is clear to a height of about 12 or 14 feet, where it branches into an ample head of deep glossy foliage. Even in winter this is a noble tree. In general character it is intermediate between the Holm and Turkey Oaks, but the bark is more cork-like than that of either of these kinds. To the left is a remarkably fine Cork Oak (*Quercus Suber*), in vigorous health, and between the two stands a handsome purple-leaved Beech, the dark purple—almost black—foliage of which contrasts well with the varied greys and greens afforded by that of the Oaks. The rich beauty of these three choice specimens must make all who see them long for a few inches of soil in which to plant such trees, seeing that they always advance in

high, and specimens of *Cupressus macrocarpa* and its allies, *C. Lambertiana* and *C. Goveniana*, are equally fine. The upright or spiral Golden Yew is represented by two splendid trees 12 or 14 feet high, and a pair of the upright Italian Cypress, graceful as Bamboos, are fully 20 feet high. *Abies Pinsapo* does well here; the largest specimen is 30 feet in height, the growth being beautifully coloured; while *A. nobilis* and all the choicer Firs seem equally at home. Conifers are every year raised from seed by the thousand, and in looking over the beds it is surprising to note the variation observable in the young plants. In a plantation of Lawson's Cypress alone we picked out half-a-dozen well-marked forms, each distinct either in habit, density, or colour. The common dark-foliaged form is most common, but there is a spiral form of a fresh and much lighter green tint nearly as dense as *Thuja aurea*. Another variety, again, is quite glaucous—nearly silvery; in fact, there are white and yellow variegated forms, and others that differ greatly in habit of growth. The different varieties of the common Yew, again, are well-nigh endless—from dwarf dense masses, only a few inches in height when fully developed, to the towering spiral forms, and the sombre-branched common or native Yew, as seen in country church-

yards. Even taking such a plant as the Laurel (*Cerasus Laurocerasus*) as an example of variety, there are four distinct forms grown here in quantity; the common Laurel; its creamy variegated variety; the Colchican Laurel, which is best adapted for bleak and exposed positions; and the Round-leaved Laurel (*L. rotundifolia*), perhaps the most distinct, and best worth growing as an isolated specimen in the shrubbery border or on the lawn. Its foliage comes nearer in form and size to that of *Magnolia grandiflora* than that of any other shrub, and it is of the same fresh, glossy, green colour. *Berberis* (*Bealii*) *japonica* is grown here by the acre, the foliage being remarkably fine, and in some cases beautifully variegated with creamy-yellow and brownish-crimson. The immense collection of Oaks grown is surprising, and includes all the most effective species and varieties, such as *Quercus coccinea*, *Q. Cerris*, *Q. Suber*, *Q. Ilex* and its numerous long and short-leaved forms, *Q. heterophylla*, no two leaves of which are alike; *Q. Fordi*, one of the best of the evergreen varieties, and something like a *Phillyrea* in habit; it bears cutting well, and forms very compact pyramids; *Q. palustris*, *Q. seneciofolia*, or Groundsel-leaved Oak, with curiously-cut foliage, the under sides of the leaves being of a bluish or glaucous tint, which gives it a distinctive appearance. Elms, Limes, Chestnuts, Beech, Planes, Acers, Willows, and other deciduous trees, are equally well represented.

Rock Garden.

Here we have another feature which should never be wanting in gardens of any pretensions as regards completeness. In some respects this rockery might be compared with that of Messrs. Backhouse, at York, and yet it possesses a character peculiarly its own. The garden was constructed under the personal superintendence of the late Mr. Pince, and the result is highly interesting, as nearly every jutting crag or rounded boulder affords root-hold or shelter to some distinctive kind of vegetation. The paths wind effectively under sombre Yews and other evergreens, and here and there open spaces, trickling rills, and limpid pools afford room for the more hardy exotic plants that require shelter, and for marsh plants or aquatics, and Ferns of various kinds. In some places the rocks are draped with *Linaria* in a peculiarly effective manner, and one can scarcely recognise the half-starved little wall plant in its long streaming wreaths of fresh green foliage, as it here hangs gracefully from a jutting boulder or little rocky promontory. The variegated variety of Fortune's Bamboo (*B. Fortunei*) grows luxuriantly here, some of the stems being fully 2 feet in height, and the foliage far better developed than is generally the case when this plant is cramped in pots. In company with evergreen *Polypodiums*, *Polystichums*, and *Lastreas* this plant is very useful, as its silvery leaves contrast well with the darker shades of green. Another even more elegant and stately species, *Bambusa gracilis*, luxuriates in one of the sheltered spaces, and, even in December, is an object of much beauty. Planted by ponds or streams in the many warm and sheltered dells to be found south of London, this graceful plant would always charm the eye. It would revel in the humid and Fern-fringed glades of the Isle of Wight, and even in less-favoured localities it might be made one of the finest features in the cool conservatory or winter garden. There is a fine plant of it in the Chelsea Botanic Garden, and there should be one even finer in the well-kept temperate-house at Kew. Another distinct plant met with here, which produces excellent effects in juxtaposition with massive sombre-tinted Conifers, is the White-washed Bramble (*Rubus biflorus*), each stout stem being white, as suggested by the popular name. It thrives here with unabated vigour, and its bright appearance is greatly enhanced by the dark-leaved Yews and Firs around it. A specimen of the Maiden-hair Tree or Chinese "Ginko" (*Salisburia adiantifolia*) towers upwards to a height of between 40 and 50 feet, its spiral or slender conical habit contrasting well with flat-headed Cedars and dwarf Firs. Here is another open space and a charming group of sub-tropical plants, consisting of *Arundo Donax*, *Bambusa gracilis*, Pampas Grass, with elegant curling leaves and feather plumes of burnished silver-like hue, sword-leaved Yuccas, *Ruscus racemosa*, Ferns, and other distinct-habited plants, while here and there the fresh green drapery of the rocks is enlivened by variegated *Euonymus*

and Ivies. The sheltered position of this charming garden makes it a cosy home for many rare and beautiful Conifers, a class of plants in which the Exeter nurseries are second to none in the kingdom. Among these are *Cephalotaxus Fortunei*, *Thujopsis borealis* (a fine specimen, 30 to 40 feet high) *Cupressus Lawsoniana argentea*, a fine and distinct silvery variegated form of Lawson's Cypress, *Torreya myristica* and its ally *T. horrida*, a columnar-habited plant with sharp-pointed, almost spinose foliage. Both species are very ornamental and deserve culture in select collections as beautiful souvenirs of a good botanist, and a useful man. Here are some fine fresh hemispherical masses of the dwarf *Abies* (*Picea*) *Clanbraziliensis*, and a plant of the curious drooping *Abies monstrosa* is worth notice. Green and golden fastigate Yews seem here quite at home. The uses for a rock-garden like that here described are twofold. Sheltered from rough winds and nipping early and late frosts, many tender plants here present a fresh and luxuriant appearance unattainable on the open lawn or shrubbery borders, while during the broiling hot days of summer, when shade and retirement are so desirable, a garden of this description affords, if well designed, scores of shady nooks, dells, little glades, and overhanging bowers, where one can read or study undisturbed.

The Italian Garden.

This, as its name implies, is a portion of the extensive ground set apart for Conifers, flowers, and foliage plants, arranged in a somewhat formal or geometrical manner, in oblong beds, among which some handsome vases are interspersed with excellent effect. Down the centre is a wire-covered walk, over which climbing Roses, Clematis, Honeysuckles, and other suitable plants are trained. The Japanese Honeysuckle (*Lonicera brachynema aurea variegata*) flowers and fruits freely here, the latter being rather a rare occurrence in English gardens. During the summer and autumn months some excellent results are obtained by a judicious use of bedding plants, by which bright shades of colour are obtained, and these are duly balanced and harmonised by a plentiful sprinkling of sub-tropical plants and dark green shrubs and Conifers. Here are some admirable examples of dwarf hemispherical Golden Yews, and others of a dark green fastigate form for contrast, together with fine rounded masses of the dwarf *Abies Clanbraziliensis*. Among sub-tropical plants used here, *Arundo donax* was very ornamental even in December, forming great tufted masses, the tallest stems being 12 feet in height; some of the great-leaved *Solanums* were also quite fresh, and *Cineraria maritima* was as silvery as ever. The vases are furnished with Yuccas during the summer months, Yuccas being better fitted for such a position than bedding plants, and plenty of colour is obtained in the beds below. We here noticed some fine standard Portugal Laurels in tubs, their semi-hemispherical heads being faultless in shape. Two splendid specimens were presented to the Royal Botanic Society's Garden, Regent's Park, some time ago, by Dr. Woodman, and have there been much admired.

Stove and Greenhouse Plants.

A fine stock of tropical foliage and flowering plants is cultivated here, some of the specimens being remarkable for their health and vigour. At the time of our visit a little lobby at the entrance to one of the Orchid-houses was gay with different varieties of *Epiphyllum truncatum*, one of the best and most useful of all winter-blooming succulents. The plants here were worked on the *Pereskia* stock, which elevates them 9 or 10 inches above the rim of the pot, and gives to them a far more elegant appearance than they possess when grown on their own roots. Here, also, *Gesnera cinnabarina* was very showy, the growth being very robust and healthy, and the flower-spikes of large size. This makes a very showy winter-blooming plant if the tubers are potted in rich sandy soil and grown on in a warm and equable stove temperature. The reason so many growers fail to flower it satisfactorily is, doubtless, owing to some irregularity in temperature or moisture at the root. What most surprised us, however, was a number of *Bougainvillea glabra*—small plants, little over a foot in height, blooming freely in 48-sized pots. These were very conspicuous on account of the delicate and peculiar mauve

colour of their floral bracts, which are quite distinct from anything else, and invaluable for bouquets and other decorations during winter. The main secret in their culture is to strike cuttings early in the spring, and to grow them on in small pots close to the glass in a moderately warm stove. This induces short-jointed and not over-vigorous growth, which rarely fails to produce flowers at this season. Standing in a shallow tank of tepid water in the Orchid-house was one of the finest specimens of *Higginsia* (*Camphylobotrys*) *refulgens* we ever saw—a splendid and vigorous mass, fully 4 feet through. This is a very old and neglected stove plant that is unsurpassed for richness of colouring when well grown, and in this specimen the rich velvety greens, browns, and purples were especially well developed by good culture. *Marantas* do remarkably well in the same house; a plant of *M. Veitchii* was 3 feet in height, and well furnished with richly-tinted foliage. *M. rosea-picta* was revelling here, some of its leaves—blade and stalk—being over 2 feet in length, the leaf itself being quite 10 inches broad, and very vividly coloured. This plant is of a very pleasing metallic-green tint, quite distinct from any other plant we know, and deserves culture on account of its distinctive peculiarity. *M. illustris* was equally luxuriant, and a fine specimen of the old but, as yet, unsurpassed *M. (Calathea) zebrina* was a mass of rich green and black-striped foliage. In the long stove two plants of *Anthurium regale* were making a very vigorous growth. This is an effective exhibition plant when well managed, but unfortunately it travels badly, the young foliage being as delicate as it is beautiful. Here are also several fine specimens of *Clerodendron Balfourii* trained on globe trellises, and also three or four equally fine strong plants of *Stephanotis floribunda*, fresh and healthy, but of course not in flower. One of these plants bore over 100 fine clusters of flowers, all open at once during the past season, and was much admired, it having been exhibited at the Plymouth Horticultural Society's Exhibition. On one of the side benches we noted hundreds of small decorative Palms, and a fine young stock of *Stephanotis floribunda* in small 60-sized pots. In this house, and covering some 30 or 40 feet of the roof, is one of the finest plants of the old, but too rarely seen, *Hoya imperialis* that could be found in this country. Even when not in bloom, its extremely vigorous growth and great leathery foliage, are quite sufficient to attract attention to it as a stove climber. This plant is now showing quantities of flower buds, and is worth a place as a winter-bloomer. At the lower end of this house are numerous specimen foliage plants, including fine examples of *Alocasias* and *Anthurium magnificum*, in habit resembling *A. regale* previously referred to, but whose foliage is rounder and scarcely so elegant in shape. Here also are four or five little cases devoted to a small collection of *Anætochili*, including nearly all the more common kinds. It is a pity these plants are not more generally grown in plant-stoves, for few foliage plants are more beautiful. When closely examined, each leaf will appear like a velvet cushion richly embroidered, and marked with gold, crimson, yellow, or bronze. We here noted a splendid specimen of the extremely rare Fan-leaved Palm, *Prichardia pacifica*, with twelve fine drooping fresh green leaves. This is valuable for exhibition purposes, being distinct in form and of compact habit of growth. In another plant-stove we found a vigorous specimen of *Psidium Cattleianum* (the purple Guava), which is just now profusely covered with fruit. A sunk pit in the centre of this house is devoted to tall-growing specimen Palms and tree Ferns; among the latter were fine plants of *Cibotium regale* (a species remarkable for the rufous, hair-like covering at the base of the stipes), *Dicksonia antarctica*, *Cibotium princeps*, *Cyathea medullaris*, and a noble plant of *Livistona borbonica*, remarkable for its ample, fresh, green, fan-shaped foliage. *Gleichenias* do well here, two fine specimen plants of the deep green *G. dicarpa* and the glaucous-tinted *G. Speluncæ* being especially noticeable for their freshness and beauty. These rare Ferns are valuable, either for show purposes or for supplying choice fronds for the very finest of bouquets and floral decorations. We also noticed good specimens of *Cocos Weddelliana*, *Phœnicophorium sechellarum*, and *Verschaffeltia splendida*, with its stem and canopy of ample foliage supported a foot above the soil of the pot by the stout buttress-like aerial roots. *Ixoras* are a speciality

here, and very fresh and healthy they look just now, without any marked traces of the well-known spot, which, if once it gains a footing, so soon destroys the beauty of the plants. Here we noticed fine specimen plants of *I. Colei*, *I. coccinea*, *I. javanica*, *I. amboynensis*, *I. Williamsii*, *I. Prince of Orange*, and other equally well-known forms of this grand old genus. Here, also, we noticed a remarkably fine specimen of the new *Dipladenia Brearleyana* in first-rate condition, promising well for next year's exhibitions; and, beside it the new *Anthurium floribundum*, a white-spathed variety, is blooming freely, as implied by its specific name. Here, also, we noticed a fine-foliaged plant labelled *Coccoloba* sp? a strong-growing shrub, reminding one of a broad-leaved *Ficus* in habit. This is distinct and new, promising to become, when better known, a highly ornamental decorative foliage plant. Finely-coloured plants of *Croton majesticum* and *C. Johannis* stand here close under the glass, and some fine globe-shaped specimens of the brilliant orange-scarlet *Rondeletia speciosa* were flowering very freely. One of the small range of span-roofed houses here is devoted mainly to the growth of specimen *Crotons*, among which are some very fine highly-coloured examples, varying from 2 to 3 feet through. Among the varieties here may be noted *C. irregulare*, *C. undulatum*, one of the best; *C. Hillianum*, an improvement on the old *C. pictum*; *C. aucubæfolium* and *C. maximum*, with large-sized golden-blotched foliage; *C. angustifolium*, *C. pictum*, and, of course, the old but beautiful *C. variegatum*. A plant of *C. Wisemanii* had just returned from the Manchester Exhibition, and was of the most brilliant golden colour imaginable. This is perhaps the finest of all the new *Crotons*, and deserves to be grown in all collections of fine foliage plants. In one of the stoves here we noticed a fine batch of *Eucharis amazonica*, which is here largely grown as an exhibition plant, and also for its pearly white and sweetly perfumed flowers.

Orchids.

These beautiful plants are well represented, and are in a fresh and healthy condition, many of them being now in bloom. Three or four fine specimens of *Angræcum eburneum* are throwing up their flowering stems, and on one plant we counted four of these nearly as thick as one's little finger. *Aërides odoratum* does remarkably well, and is represented by dozens of healthy plants. A fine plant of *Cymbidium giganteum* bore an eleven-flowered spike at the time of our visit. We also noted several good plants of the yellow-flowered *Dendrobium densiflorum*, and *D. chrysotoxum* and *D. aggregatum majus* seem to do well. A batch of imported *Vandas*, including *V. Bensoniæ*, are growing freely. A choice collection of *Phalanopsis* occupies one end of a house here, and the plants seem perfectly at home, the leaves being remarkably plump and fresh, and their roots clinging vigorously to the baskets and pots in which they are grown. Many plants of *P. Schilleriana* are now throwing up stout flowering spikes. Several plants of the *Flor del Meurtos* or *Oncidium tigrinum* are doing excellently; and a batch of *Calanthe vestita rubra* and *C. v. lutea oculata* are now blooming freely with the soft, rosy, lilac-flowered *C. Veitchii*, a plant well worth growing by the dozen in every plant-stove where winter-blooming plants are desired. *Cypripedium insigne* is another old favourite that does well even in a warm greenhouse, and flowers regularly during the autumn and winter months. We noticed some strong plants of the Australian Rock Lily, *Dendrobium speciosum*, growing well, together with the vigorous *D. Calceolare*, a most beautiful plant when in bloom, and of a robust habit if liberally treated; indeed, it is one of the few Orchids to which liquid manure may be supplied during their growing season with advantage. In the cool Orchid-house we found *Odontoglossum Alexandræ* and *O. Uro-Skinneri* growing very freely, and the fine old *O. grande* was flowering well, bearing five or six great golden-yellow brown-blotched flowers on a spike. This is another plant that will succeed perfectly in any moderately warm plant-stove if properly supplied with fresh air during summer. The same may be said of a plant of the old *Oncidium flexuosum*, which was laden with its pale-golden flowers. One of the small houses here is devoted to the culture of *Lælias*, *Cattleyas*, *Dendrobes*, *Coelogyne cristata*, and other intermediate-house Orchids; and here we noted an ingenious and useful contrivance, which is

well worth general adoption elsewhere, especially in localities where there are mineral impurities in the soil which renders the supply from wells, &c., almost useless for plant culture indoors. In the centre of the house is a bed or pit about 3 feet in height, and inside this is a cemented tank capable of holding many thousand gallons of rain-water, which, instead of being allowed to escape in the usual way, is here conducted into this tank or reservoir, from which it can be drawn into a smaller tank below the level of the floor as required, the last-named tank being large enough to "dip from" with the watering can, and thus save time. The top of this reservoir is slated, and thus forms a stage on which the plants are arranged. It is a well-known fact that rain-water is the best for plant culture, and tanks constructed like that just described, or even excavated below the surface of the floor, are much to be recommended.

The Glasshouses.

The conservatory or show-house for ornamental-flowering and foliage plants is fully 150 feet in length by about 14 feet in width. Here we found a brilliant show of Chrysanthemums, Cyclamens, scarlet Pelargoniums, well-bloomed plants of the crimson-scarlet *Schizostylis coccinea*, and numerous other well-known winter flowers. We also noted some fine densely-furnished specimens of *Libocedrus Donniana*, one of the freshest and greenest of Conifers, and one which succeeds well under pot culture if liberally supplied with water at the roots. A fine specimen of *Chamærops excelsa* var. *argentea* in this house, too, was remarkable for its slender fan-like foliage, which, instead of being green, as in the normal form, is in this variety of a silvery hue. At each end of this conservatory is a choice collection of succulents, and the roof is well furnished with the best climbing and trailing plants. *Tacsonia Van Volxemii* was fruiting freely; and, singular enough, some of the leaves at the apex of the young growth were simply cordate-ovate, slightly woolly beneath, as in *T. insignis*, and not, as usual, ternate. Other climbers, as *Rhynchospermum*, *Passiflora racemosa* (the latter beautifully in flower), and *Jasminum revolutum*, luxuriate here and produce plenty of cut bloom. Both the red and white-flowered forms of the *Lapageria* are quite a speciality here. Some may not know that there are, at least, half-a-dozen distinct forms of the common *Lapageria rosea*; indeed, the plant is an extremely variable one, not only as regards size and colour of the flower, but also in habit of growth and size of foliage. In some varieties the flowers are so deeply coloured that the white blotching and mottling inside are nearly absent, and the flower has a closed appearance. Others have large pale white blotched segments, which expand in a bell-like manner at the mouth, and these varieties are very beautiful when trained on a roof and looked at from beneath, while the closed but rich coral-red or crimson flowers look best on a wall or when viewed horizontally. We imagine that but few cultivators, even in the sunny south, regard this beautiful plant as a hardy climber; but, in sheltered positions, we have known it to withstand severe winters as far north as the Trent when carefully mulched or otherwise protected at the root during frosty weather. Mr. Lamb planted out some specimens of it in the grounds at Colston Bassett, Nottinghamshire, a few years ago, and these succeeded moderately well. Here, in the Exeter nursery, a specimen literally luxuriates on the outer wall of the conservatory, making even finer and stouter growth than plants indoors. Last December, when we saw it, it was flowering profusely, and a few weeks

previously it had on it upwards of a hundred flowers. Our illustration is prepared from a photograph, and gives an exact representation of the plant. We have often received flowers of this plant from other favoured spots in Devon, and from the Isle of Wight; but we question whether there is anywhere a finer specimen growing out of doors than that to which we have just alluded. A vigorous specimen of the white variety was blooming freely, planted out in a cool Vinery, and promises to soon cover the back wall. The Camellia-house (200 feet long) is a striking feature, the plants being splendid specimens, which are rivalled only by those in Mr. Scott's conservatory at Sundridge Park, or the fine old examples at Chatsworth. The finest specimens, principally double whites, are planted out in the central bed of the house, and are fully 20 feet high, and nearly as much through, and these, at the time of our visit, were profusely covered with flowers and buds. The old Double Whites, *Candidissima* and *Fimbriata*, are, perhaps, best worth culture where cut flowers are desired, white flowers being nearly double the price of the coloured kinds in the market. Some plants are in large tubs, and the side walls present a very beautiful appearance, being covered

with a dense sheet of glossy green foliage and with a profusion of flowers. This house is another striking illustration that wherever practicable it is by far the best plan to plant out Camellias in positions where they can fully develop themselves, especially if cut flowers in quantity are desired. Other houses are devoted to Pelargoniums, *Ericas*, Camellias in pots, Indian Azaleas, Gardenias for cut flowers and bouquet making, and one house is nearly filled with strong plants of the fragrant flowered *Eucharis amazonica*. A new span-roofed house has just been erected for Tea-scented Roses, and is already planted with *Maréchal Niel*, *Safrano*, and other leading varieties.

Fruit-houses.

Two long pits are devoted to Pines, and contain a healthy stock of clean and vigorous fruiting and succession plants. There are also several fine ranges of Vineries and Peach-houses, the produce being in most cases gathered before the time of our visit, with the exception of a house of Mrs. Pince's Black Muscat—a well-known late keeping Grape of a very delicate flavour, and well worth a place in the most select collection of late Grapes. It is equal to Lady Downe's Seedling in keeping qualities, while its flavour is fully equal to that of Snow's Black Muscat, and it sets more equally than the last-named variety.

The Propagating Department.

As may be imagined in a nursery of 100 acres, with a small village of glass-houses, this is a very important department. In the propagating houses (parts of which have been lately remodelled by Dr. Woodman, to afford increased facilities for the supply of new and rare Conifers and choice exotic plants), we found everything in perfect order. Among a whole host of other things, Tea Roses were being propagated by the hundred—we might almost have said thousand—at the time of our visit. The stocks used are the Manetti and seedling Briar. What most struck us was the skill shown in grafting these. Scions and stocks are selected of equal thickness, a sloping or whip-graft cut with a keen blade, and the stock is ready. Another cut forms the base of the scion, and the two are fitted together accurately in far less time than it has taken us to describe the process, and lashed firmly in their places by a few turns of bast, no tonguing being resorted to. This is the quickest and simplest form of Rose grafting we have

A well-grown dwarf Palm.

ever seen. New Azaleas and Camellias we found by the hundred treated precisely in the same way, and the union between scion and stock soon takes place in a humid case. Among other rare plants freely propagated here we were glad to see the coral-berried *Nertera*, a charming plant, rare in both gardens and nurseries. Some of the rarest and best of the *Gymnogrammas* are being freely multiplied from spores, such as the silvery *G. peruviana*, a specimen plant of which measured fully 3 feet through; another plant of the bright golden *G. Lauchiana* being even larger still. Here, also, we found a splendid stock of *Pelargoniums*, including most of the novelties obtained by Turner, Cannell, and other raisers and growers. Many of the rarer *Conifers* are here propagated by grafting, as well as from seed. There is a needless prejudice entertained by some growers against grafted *Conifers*; but we have it on the authority of Mr. Fowler, who has formed one of the most striking of all private collections of *Coniferæ* at Castle Kennedy, that grafted plants are fully equal there to the same kinds raised from imported seeds. Some of the grafted specimens at the last-named place have themselves borne perfect cones; and seedlings from these, again, are as healthy and as vigorous as those from seeds sent by collectors in the Rocky Mountains, Japan, and elsewhere. Among the kinds propagated by grafts, we noticed *Abies firma*, *Picea amabilis*, *P. nobilis*, *Cupressus Lawsoniana argentea*, *C. torulosa*, *Abies Pinsapo* var., and lastly but by no means least, the curiously whorl-leaved Umbrella Pine of China and Japan (*Sciadopitys verticellata*). One of the most common of stove plants, the crimson and purple-flowered *Ipomœa Horsfalliæ*, is here readily propagated by grafting it on the fleshy roots of other species, as *I. Learii*. *Wistarias* and Moutan *Pæonies* are grafted on their own roots as the readiest plan, although *Wistarias* root freely by layering, and we have repeatedly struck Moutan *Pæonies* from cuttings of the young growth, leaving on a heel of the old wood. Among other hardy subjects propagated in quantity we found hundreds of healthy plants of the true Exmouth *Magnolia grandiflora*, which is, perhaps, the best of the whole group. During wet, or unfavourable weather many of the hands are employed in extracting the seeds from Pine and Fir cones, and in preparing other tree and shrub seeds for sowing. Stocks for Plums, Cherries, Apples, Pears, and Apricots, we found by the hundred ready for operations in the spring. Quince stocks are largely used for bush Apples and Pears, Muscle stocks for Plums and Peaches, and Brompton stocks for Apricots.

Roffea Grass.—I agree with Mr. Hobday (see p. 295, Vol. V.) that for tying plants this material is much better than common matting or twine. It is strong and tough. It may be used for tying all kinds of plants, Vine rods, Vine shoots, &c. It is soft and pliable, and, therefore, offers no hindrance to the free expansion of young and tender growths. It is sold by weight by nurserymen, and is much cheaper than twine, or cutting up a good mat for tying purposes which I have often seen done.—J. MUIR.

THE INDOOR GARDEN.

PALM CULTURE.

PALMS have now become universal favourites, and their popularity is such that they are no longer confined to extensive collections in large horticultural and botanic establishments, but have been introduced, through nurserymen, to decorate and enliven the apartments and assembly rooms of our cities. There is a strongly marked individuality about this order of plants which strikes even the ordinary observer, and the effect produced is all the more heightened when large and small specimens of various species are grouped together, and also when they are associated with tree Ferns,

Cycads, Bananas, Marantas, Caladiums, and various forms of a more or less tropical character. Their symmetrical appearance, their fan-shaped and pinnate leaves, the charming shades of green which they assume, the graceful curve of the leaf-stalks, the rugged appearance of the stems, the development of the flowering process on a spadix, their intrinsic value and durability all combine to raise them in public estimation. Their culture is attended with little or no difficulty, and yet to produce and preserve healthy well-developed specimens much attention and labour are requisite. The soil should consist of a good free fibry loam, and when intended for plants in a young root-forming condition, it should be thoroughly disintegrated with the fingers, and combined with a quantity of older mould of the same description, together with an admixture of sand. If good balls of roots are already formed, the potting material may be more roughly dealt with, and may contain less decomposed material. As these plants succeed admirably with small shifts at long intervals, it is the more necessary that a large proportion of fibre should be present in the soil, inasmuch as the mass will thereby take longer time to decompose and get exhausted. It will, moreover, form a better rooting medium, keep more porous, and so minister better to the sustenance and structure of

A well-grown dwarf Cocos.

the plant than it would otherwise do. In the process of shifting, the points to be observed are, limitation of root-space, which should in no case exceed 6 inches, and this only for such as have attained large dimensions in tubs or boxes; efficient drainage to prevent choking up, until the roots find their way among the corks. To secure this, rough pieces of turf should be laid in the bottom of the pit or tub previous to filling up with soil. The whole should be made sufficiently firm by packing the soil carefully with a rammer. Thus a large amount of turfy material will be compressed within a small compass, thereby increasing its stamina. The best time for this operation is after the plants have made their season's growth, and before they go to rest; but it may also be performed during spring, care being taken that the roots are not mutilated so as to impair their action. A good margin or basin should be allowed for water, which

should be freely administered; the indispensable condition of success in Palm growing is abundance of moisture at the roots, and more or less in the atmosphere. If Palms are stinted as regards water supply, during their period of activity, the foliage, instead of wearing that freshness and lustre, so pleasant to the eye, speedily assumes a parched and sallow complexion, and the growing power of the plant receives an unwholesome check. Neither should they be subjected, while dormant, to the drying-off process, as it is termed, for, though less impatient of drought in winter, they cannot long be subjected to the influence of fire-heat without water with impunity. Another and most essential provision with reference to health and vigour, is shade. Where considerable numbers are grown, the capacious leaves of such as have attained goodly dimensions will furnish an awning to their less stately bretheren; but those which are directly exposed to the sun's rays must be shaded, either by means of stained glass, temporary screens, or, better still, a judicious combination of stone and glass in the construction of the house. By such means, the water will be utilised by reducing the evaporation to a minimum, and a moist atmosphere be steadily retained, provided that the syringe is plied daily. In order to counteract still further evaporation from the soil, the surface of the pots or tubs, especially those containing lately-shifted plants, should be mulched with living Sphagnum, or whatever may be deemed suitable. Another measure conducive to the well-being of the Palms is cleanliness, a condition dependent upon the regular employment of the garden engine, syringe, soap, and sponge. The accumulation of dust or other impurities on the leaves impairs healthy leaf action. War must constantly be waged against scale; or, rather, the policy that prevention is better than cure should be adopted. The appearance of this pest is frequently the result of starvation, or uncongenial treatment of some sort. Extreme fluctuations of temperature should be avoided, but I would not advocate high temperatures. Plants in which growth has been solidified by a due admission of light and air, will winter in a minimum temperature of 45°; but where they are intermixed with a miscellaneous assortment, it will be advisable, as a safeguard against cases of damping off, not to let it fall below 50°. The seeds of Palms require a high and steady bottom-heat. The Date, however, may be raised in an ordinary greenhouse. *Seaforthia elegans* is often found springing up self-sown at the bottom of the parent stem—a fact which would indicate that Palm seeds should be covered lightly, and also that they should be sown as early as possible after they are ripe. In the arrangement of Palms, whether temporary or permanent, each should be allowed room sufficient to show off its outline to advantage; with plenty of room, too, that flabby pent-up character is obviated which crowding always entails.

J. S.

ORCHIDS WITHOUT ORCHID HOUSES.

THE extended cultivation of these plants is greatly retarded on account of the erroneous impression that separate houses are required for each distinct class, and the error is one by which the owners of plant-houses are made to lose one of the greatest charms that their glass structures ought to afford them. I do not wish it to be understood that they can be grown better in the mixed style than in a separate house; but I wish to convey an idea of the enhanced effect that is given to their lovely flowers by contrast with the magnificent foliage of *Musas*, Palms, Tree Ferns, *Alocasias*, &c. The majority of aerial Orchids, suitable for stove-houses, delight in the shade of overhanging foliage, and may be grown between the specimen plants and roof-climbers in space that could not be utilised except for basket plants, when, with their bloom hanging in the best position for minute observation, they will at all times prove objects of much interest. I will simply give our mode of cultivating that queen of Orchids, *Phalænopsis amabilis*, which will be found to answer for most kinds requiring a high moist atmosphere. For economising space, we grow these Butterfly plants in rustic baskets, made with rough-barked wood and pieces of copper wire, of sizes to suit the specimens. These are hung on wires stretched from one rafter to another. The compost we use is fresh Sphagnum Moss with a little charcoal, peat, or potsherds; but the main point of success is a high moist temperature, such as suits fine-foliaged plants, for these aerials live on the atmosphere more than on the compost they are in. During summer we keep the central beds of

stoves filled with water, which constantly gives off vapour. In winter we find sprinkling the paths and surfaces of beds sufficient as the blooms last longer without spotting in a drier atmosphere than that maintained in the growing season. The temperature in which we find them do best is a mean of 65° for winter and 75° for summer. If at any time the plants are exposed to a heat much below 60°, except for a short period, their leaves soon assume a sickly yellow hue; and, although not easily killed, they are slow to recover from injury. As regards freedom of bloom, I do not think we have any plant that produces such a display throughout the whole season as *Phalænopsis*, which are always in bloom. On plants in baskets less than 6 inches square we have several with from fifteen to twenty fully expanded blooms, from 3½ to 3¾ inches across. As the spikes of this variety continue to produce successional batches of bloom, I have, sometimes, as soon as one lot begins to fade, pinched the terminal bud off, so that the plant might not exhaust itself, but in a few days they invariably send out two or three branched lateral spikes, producing about six or eight flowers, which are invaluable for cutting, for ladies' hair, button-hole bouquets, &c. We have had all through the winter upwards of one hundred expanded blooms in one stove. Mingling and contrasting admirably with them are long sprays of *Passiflora princeps*. The foliage plants beneath look all the better for their lovely flowers, while they in return get the benefit of the foliage. Do not then range them in rows like Cabbages, in houses by themselves; but grow them as they are grown in their natural state, where they are found garnishing the stems of giant trees, and festooned with entangling creepers; although somewhat expensive at first, they do not lose, but yearly increase in value as they do in size, which cannot be said of all plants.

Henham Garden.

JAMES GROOM.

Treatment of Small Seeds.—I believe small seeds more frequently fail to germinate after they are sown than large ones. Various reasons might be assigned for this, but I think the principal cause lies in the manner in which small seeds generally are treated, especially those sown in pots and pans. The latter are in most cases filled very loosely with open soil, and rendered extremely porous by the application of large quantities of leaf mould and Mushroom-dung. Upon the surface of this the small seeds are then strewed, and a good watering is forthwith administered. This, undoubtedly, has the effect, in nine cases out of ten, of carrying the greater part of the seeds far down into the open mixture, where they have but the remotest chance of germinating. Should they do so, there is so much length of young and tender stem between the root and the surface of the soil that the young plants damp off before they are many days above the ground. Such failures are seldom attributed to mismanagement, but usually to bad seed. The plan I have adopted with perfect success is to have the surface of the soil, where the seed is to be placed, composed of the finest-sifted matter, through which the seed will not easily pass. When the seed is sown, I never give a drop of water on the surface, but let the pot or pan into a flat filled with water. The soil soon gets moist, while not a single seed is shifted from the position in which it was originally laid; and I never have occasion to suspect the quality of the seed. The flat is not kept constantly filled, but supplied with water as required, and this should never be given on the surface until the young plants are well up. There is another practice I have often observed in sowing seeds—that of filling the space between the soil and the rim of the pot so full of water as to flood the seeds, when they are nearly all washed on one side. When these germinate they often come up so thickly as to smother each other, and much damping usually follows. This tends directly to spoil seed and plants; on the other hand, the flat system saves both, and may be successfully practised by all. Those who cannot afford to get a common garden flat may use an old tea saucer with the same practical results.—J. MUIR.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Lapagerias from Seed.—How should I proceed to raise a few seedling *Lapagerias*?—DELTA. [Sow in pots or pans filled with light soil, as soon as the seed-pods are fit to be taken from the plant; place them in a temperature from 60° to 65°, and keep them well soaked with water. They will come up about a month afterwards, and will not then require so much water. If properly treated, they will flower during the second year.]

Begonia ascotiensis.—A fact little known (says the "Revue Horticole") is that this *Begonia*, so common and turned to such good account with us, is scarcely known in England, although it originally came from there, M. Keteleer having a few years ago bought it of Mr. Standish, of Ascot, for half-a-crown. Messrs. Thibaut and Keteleer sold such plants as they raised of it at an equally reasonable rate, and it was not until last year, when M. Duval was awarded a prize for some fine specimens of it, that its value became apparent. Plants of it, which at one time could be bought for a shilling or little more, now realise as much as twelve francs or half-a-sovereign.

PROPOSED EMBELLISHMENT OF THE ORMES HEAD.

THE scheme for planting and laying out in an artistic manner the noble Welsh headland called the Great Ormes Head (to which allusion has been lately made), is so important a one to the horticultural public, as well as to tourists and those who visit this, the most celebrated of Welsh watering places, in search of health and strength, that I trust it may not be allowed to fall through for want of adequate support. If carried to a successful issue the beauty of one of the grandest and most picturesque portions of the mountain scenery of North Wales would be enhanced, and additional inducements held out to the public to visit the spot. I gather from the remarks to which I have referred that the scheme is at present in its initial stage, although your correspondent mentioned a limited liability company, which possibly is now in course of formation. As he alludes to obstacles that may be thrown in the way of the undertaking, it will be as well to consider what in reality they are. The chief one appears to be the infringement of manorial rights; and, doubtless, it would be very inconvenient to find, when the capital had been subscribed and the work commenced, that the lord of the manor—that most mysterious of all invisible magnates—had some insuperable objection to the scheme, and was empowered to act as he thought fit in the matter. Another drawback, for it can hardly be correctly named an obstacle, seems to be the apathy and indifference with which the local landowners have met the proposal. I am confident, however, that these difficulties are far from being insurmountable. It would be an easy matter to discover who the lord of the manor is, and what his claims are, and there can be no reasonable doubt that the satisfaction of the latter would be a less serious matter than has been supposed if a guarantee by the company for full compensation for any infringement of rights be given. It is possible, indeed, that the lord of the manor himself might be induced to become a shareholder, and thus have a direct interest in the success of the enterprise. So far as the inaction of the landowners goes it would be found that their co-operation would be secured so soon as they saw an influential body of men determined on carrying out the scheme. At present the headland is of little or no commercial value, and in no way enhances the prosperity of Llandudno or its neighbourhood. The proposed undertaking would have the effect of completely altering this state of things. If judiciously planted with trees and hardy and Alpine plants and shrubs of a dwarf growth, under the superintendence of leading men in the profession, the natural attractions of the mountain would render it of absolute commercial value, and who would object to pay a small charge for the pleasure of seeing it under so improved an aspect? The glorious Atlantic sunsets, to which your correspondent so graphically refers, and the wild and romantic inland scenery will be enjoyed the more when viewed from artistically-planted grounds, well furnished with rustic seats for the convenience of visitors. In my opinion a company is far more likely to manage the matter successfully than a private individual, even if one were found ready to embark £10,000 or £15,000 in such a scheme; and once enlist public opinion in its favour, and show that, apart from the aesthetic value of the work, it may rest on a solid commercial basis, such a company might readily be formed, and the necessary capital as rapidly supplied.

L. W.

The Cinnamon Tree.—This tree flourishes in a white quartz sandy soil, and in its cultivated state it is never allowed to exceed the dimensions of a bush, being pruned down close to the ground every year. This system of close cutting induces the growth of a large number of shoots, in the same manner that Withies are produced in England. Every twelve months these shoots attain the length of 6 or 7 feet, and the thickness of a man's finger. In the interim the only cultivation required is repeated cleaning. The whole plantation is cut down, and the sticks are then stripped of their bark by the peelers. The practice of the natives in this employment naturally renders them particularly expert, and in far less time than is occupied in the description, they run a sharp knife longitudinally along a stick, and at once divest it of the bark. On the following day the strips of bark are scraped, so as entirely to remove the outer article. One strip is then laid within the other, which upon becoming dry, contract and form a series of enclosed pipes. It is subsequently packed in bales, and carefully sewn up in double sacks for exportation. Although the Cinnamon appears to require no more than a common quartz sand for its production, it is always cultivated with the greatest success when the sub-soil is light, dry, and of a loamy quality. Cassia bark is much like Cinnamon, but thicker, coarser, stronger, less delicate in flavour, and cheaper; hence, it is frequently used to adulterate Cinnamon.—Baker's "Eight Years in Ceylon."

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Rhubarb.—There are few culinary plants more generally cultivated than Rhubarb, and it is deserving of special attention in the amateur's garden. Independently of its many uses, it is in itself, when well grown, a plant of very ornamental appearance, and, if the several crops of the kitchen garden be well grown and a systematic order of cultivation carried out, no weeds permitted to grow, or the remains of past crops allowed to cumber the ground, a vegetable garden may, and always should, be made not only useful but very pleasing to the eye. To grow Rhubarb well requires deep cultivation and rich land. It will live almost anywhere, even under fruit trees, but the produce in such places is weak and puny; yet it likes shade, and will succeed well under a north wall if the situation be in other respects light and open, and in such a position the individual leaves and stalks will attain the greatest size. If the bed be 3 feet deep in soil all the better; if not, an addition of decayed vegetable matter, such as Cabbage stalks and leaf soil, with one-third of road scrapings and one-third manure, well mixed with the soil in digging, will produce heavy crops. The principal advantages of this high culture, in the case of this and similar subjects is, that the produce is better in quality, and the space necessary for the production of a given quantity less in extent. Large growing kinds of Rhubarb, like the Victoria, should be planted with a space of 6 feet between the rows, and should be an equal distance apart in the rows. Every spring a good dressing of guano or soot may with advantage be applied. For early produce, a few roots should be planted in a warm south aspect. This should be an early variety, such as Linnæus; it may be planted 4 feet apart, and, if covered with a few inches of litter during the winter, it will throw up early. All flower-stems ought to be removed as soon as they make their appearance; and, in a private establishment, a method different from that practised in market gardens should be adopted in gathering Rhubarb. In the latter, the object is to gather all; that is, to strip off all stalks that are large enough, at once and early in the season, whilst the price is high. This hard stripping naturally weakens the plant, and causes it to produce a less weight of crop during the season than it would if the removal of the stalks was more gradual, as is the case where the plant is grown for home consumption. With a view to strengthening the plants after the spring pulling, when Currants and Gooseberries get plentiful, the Rhubarb should be allowed to grow and mature its leaves; for, although a very hardy plant, it becomes much weakened if all the produce be gathered. As Rhubarb commences to grow early in the spring, the sooner the ground is prepared and the plants put in the better, when the weather is favourable. Small single crowns will do; but the larger the roots are, the sooner they will produce a heavy crop. From the latter some may be gathered the first year; but the first leaves produced should be allowed to remain.

Edgings for Walks.—Nothing adds more to the tidy appearance of a kitchen garden than good edgings to the walks. Box looks the best, the only objection to it being that it always has a tendency to harbour slugs, especially if the soil is of a strong retentive nature; in such these pests always exist in greater numbers than in land of a lighter and more sandy character. Thrift, or Sea Pink, makes a very nice edging. It is pretty when in flower; but it is open to the same objection as Box, and it also is liable to go off in some places, and become patchy. It spreads fast, and requires yearly regulation. Double Daisies are often used in small gardens, and, from the lengthened time of their flowering, have a cheerful appearance. They do not harbour slugs to any extent; but, on the other hand, from their low growth, they do not much assist in keeping the soil from washing on to the walks, and, consequently, are not suitable where gravel is used, but do better if the walks are made of sea-sand. If the two latter kinds of edging be used, any planting or regulating they require should be done when the weather is mild. Box should not be planted until later.

Peas.—Where Peas sown in the autumn, and above ground before the last severe frost, have escaped destruction, they will be much benefited by a couple of inches of dry sandy soil, such as old potting material, being put to them; this should be done by hand, so as not to break or injure their stems; a sprinkling of fine ashes on the surface will also be of use, by making it less favourable for the movements of slugs, which, with the advent of mild weather, soon begin to be troublesome. Place a few small sticks to the Peas, and run several strands of white cotton round them, to deter the sparrows whose depredations have always the worst effects when growth, as at the present time, is languid. A few Spruce, or other branches of a similar nature, may be stuck in the ground at a short distance from them; they will break the force of cutting winds, but must by no means be placed so near as to cause the Peas to draw up weakly.

Winter Spinach.—This most useful vegetable, of which a good breadth should always be sown, will, if it has been well managed,

now afford a supply. If the plants are at all close in the row it is better, in gathering, at the present season, to pick every other plant out, removing the root altogether. By this means there is more room for those remaining to grow.

Broad Beans.—A piece of ground should at once be dug and prepared for these; but it is not necessary to manure it unless poor. Broad Beans will do well after Lettuce, Cauliflower, or any crop that has required manure; they like strong heavy soil. If it is naturally very light tread the ground a little before sowing. The most economical method as to space is to plant in double rows—that is, two rows a foot apart, and an intervening space of 2 feet betwixt these and the next double row. The Beans should stand 6 or 8 inches apart in the rows, according to the nature of the land; where it is strong and rich they will require more room. Cover the seed about 3 inches deep, after sowing. If the garden is infested with mice keep a good lookout or they will destroy the crop. Where mice exist in a garden, traps should be continually set, but nothing equals a good cat that has been encouraged to frequent the garden by being fed and kept in the fruit or plant houses; if these animals are taught, from the first, to live amongst pot-plants, they move amongst them without doing harm, and are most useful.

New Ground-work.—Where new ground-work is going on, or alterations are being made, they should be pushed on as quickly as possible, for not only are such more likely to turn out satisfactorily when completed before the season gets far advanced, but, if in progress late in the winter, the general routine of spring work gets behind. New turf should (where defective in verges, under trees, or similar places) be laid at once, for, if delayed until dry weather sets in, it has a very poor appearance through the summer.

Glass Structures.—If Peaches and Nectarines are grown under glass, they should at once be pruned and tied, or their flower-buds will get so prominent as to be easily rubbed off in pruning. Do not leave too much wood because it is strong and vigorous. Such requires more room than that which is weaker, and it only leads to overcrowding, which is not the way to get good fruit, or prepare the trees for another season. They may with advantage, when tied into their allotted places, receive a coat of thin paint, made of clay and water, with a handful of flowers of sulphur added to each gallon. Use the mixture in a thin state, and very carefully, if the bloom is at all prominent. I should not advise amateurs to use Gishurst Compound for Peach trees, for, unless it be applied rather weak and early in the season whilst the flower-buds are quite small, it sometimes has the effect of causing them to fall off; the sulphur recommended for mixing with the clay paint will effect the destruction of any eggs of red spider that may exist upon the trees. See that the soil in which the roots are placed, all through the interior of the house, is in a moist healthy condition; it is a good plan to examine the border beneath, for, if any pot-plants have stood in the house, the water which has run from them may give the soil an appearance of being sufficiently wet, when it is only so on the surface. The roots of Peaches and Nectarines should never be allowed to approach a dry state; it is contrary to the nature of the plants, the buds and roots of which are never quite at rest; it is through inattention to this point that the buds frequently fall off after water has been given. Although Camellias are plants of easy growth, provided a few indispensable matters in their cultivation are attended to, they are often met with in amateur's gardens in poor condition. Less than most others can they bear being left dry at the roots. If this happens, especially whilst they are making growth, they are sure to become stunted, and the roots correspondingly weakened. On the other hand, the character the Camellia gets for liking water leads to too much being given, and this is especially injurious if the plants have made little growth, and are weak and deficient at the roots. These extremes must be avoided, for either will cause the buds to fall before opening. The same effects are also produced by too dry a state of the atmosphere, and the use of fire-heat without enough moisture in the air to correct its influence. Tie out Pelargoniums as they advance in growth, and keep them near the glass. Do not over-water them. If the soil is slightly moist it is enough, as they cannot bear to be wet at the root until later in the season, when they are making more growth. Give Cinerarias that are pushing up their flower-stems a little clear liquid manure-water once a week; Primulas flowering will also be benefited by the liquid every alternate time they require watering. Calceolarias will now be growing fast, and will be benefited by manure-water. Winter-flowering Epacris will be fast opening their flowers, and should be placed at the warmest end of the greenhouse, away from draughts. Get sufficient potting soil of the different kinds, such as peat, loam, and leaf mould, under cover, so that it may dry sufficiently for use when the time for potting most stove plants has arrived.

THE CREEPING CORNISH MONEYWORT.

(SIBTHORPIA EUROPEA VAR. ALBO-MARGINATA.)

WHY Nature has been so beneficent as to give to some plants a constitutional elasticity or power of adaptation to the most varied conditions and circumstances, and as rigidly withholds such power from others, we cannot explain; but that such is the fact no better example could be found than in the plant whose graceful adaptability for the decoration of a suspended basket is admirably represented in the annexed illustration. Our little creeping Moneywort, as it hugs the ground or gracefully hangs over a rocky ledge in its native habitat in the south west of England, or the south of Ireland, would scarcely be expected to be at home in the high temperature of our tropical Orchid-houses; yet this it really is. The majority of our hardy plants, when grown under such stimulating conditions, both as regards heat and moisture, soon exhaust their vital energies, and a short life is succeeded by premature decay. It is now a good many years since I saw a basket, whose chief occupant was a Stanhopea, beautifully draped with Sibthorpia, the introduction of which was purely accidental. Though it had been growing under these artificial conditions for more than a year, it appeared to revel in the spongy peat in which it had been introduced, and showed unwonted vigour. If then the ordinary wild form of this Moneywort is endowed with such attractions, how greatly must such endowments be enhanced, when each of its little orbicular leaves is margined with a line of silvery whiteness, a fact to which the accompanying illustration bears ample corroborative testimony. Another important qualification which it possesses, consists in the constancy of its variegation. Such freaks of Nature are often sadly prone to revert to the normal condition, especially when any increased vigour of growth is infused into them. Such is not the case in this instance, however, for among the many hundreds of plants of this Sibthorpia, in Messrs. Lawsons' nursery, not one indicates a tendency of this sort. It is, therefore, doubtless destined to become a most popular plant for many purposes. It would make a lovely edging for a greenhouse or stove shelf, where, with a little damp sand to root in, it would constitute one of the handsomest of fringes; or, for a window-basket, associated with the blue Lobelia or any pink flower, such as Saponarias; or, it might be used as a surfacing for those glasses that constitute the dinner-table parterres recently so popular. To these I might add many other possible adaptations; but when it comes into general cultivation they will suggest themselves. Beyond the fact that the flowers are so minute as scarcely to be observable, any description is rendered unnecessary, the illustration being sufficient to speak for itself. Besides being a free grower, the Sibthorpia may be readily propagated by division; and, in fact, with a little care and attention, every fragment will grow; any ordinary soil of a light character will suit it. When growing freely it is very impatient of dryness; this fact must be especially borne in mind, as suspended baskets are liable to be overlooked in the ordinary watering operations, and a single days' drought will completely mar its beauty for months to come.

JAS. C. NIVEN.

Botanic Gardens, Hull.

Cypripedium japonicum.—This is one of the finest of all the hardy Cypripediums, suitable for pit, greenhouse, and out-door culture. A very rare plant of unique habit, hitherto not found in English collections, from 9 to 12 inches in height, represented by Thunberg with a slender simple flower-scape or stem, having on the upper part a pair of nearly opposite broad, roundish, heart-shaped, sinuately-margined leaves, and a terminal solitary flower, the large front lip of which resembles the outline of a drooping Gloxinia flower cleft on the front, each side division converging. Ground colour of flower white, apparently richly and uniformly stained over with deep claret-red or crimson. The upper erect sepals are green, densely marked with vinous red dots on the lower parallel margins, oblong-lanceolate in form, 1 inch or more in length, and divaricate or spreading. More recent figures indicate some difference in the leaf structure, and favour the opinion that there may be varieties in this species. Dr. Wallace's Japanese correspondent writes, "I came across a Bamboo wood which was full of this Orchid; I find it grows best in moist Bamboo groves in leaf mould; the roots are deep, and find their way into yellow loam."

THE FLOWER GARDEN.

PROPAGATION OF BEDDING PLANTS.

SPRING propagation is a matter which demands considerable attention from those requiring many plants of this kind but who only have limited winter accommodation for them; for a few hundred plants of many kinds may be stored throughout the winter in a very small space, and be multiplied into thousands in the spring. Spring propagated plants of many sorts are preferred for summer bedding to autumn-struck ones. Geraniums are generally propagated in autumn, when large quantities of cuttings can be easily obtained from outside plants. Spring cuttings do not grow large enough for bedding out in May unless rooted very early. A few store-pots of Verbenas, rooted in autumn, are sufficient to give thousands of cuttings from February to March. Spring plants of these are superior to those of autumn. Except in cases of necessity, parent plants are generally cast away when sufficient stock has been obtained. Half-a-dozen old plants of Lobelia, if lifted and potted in autumn, are useful in spring, when every small shoot may be made into a cutting and plant. The surest and quickest way of propagating Lobelias is to have some water-tight pans filled with sand to within an inch of the rim. Put the cuttings in closely, and, when full, give sufficient water, through a fine rose, to fill the pan to the top, so that the whole may be swamped, leaving only the points above water. It will be found that every cutting will root in four days. They should then be planted in some light open mixture, with a temperature equal to that in which they were rooted, which should be 80°. I have rooted them in shallow pans in the same manner. Tropæolums may be increased from every joint of the old plant. Large plants of Heliotrope should always be grown in the greenhouse during the winter to supply sweet-scented flowers; these throw out plenty of shoots for propagation, and, planted out against a wall, give stock successively for years. Plants of the different kinds of Iresines, when kept clear of green fly, are very useful and ornamental in winter decoration; each top and joint may be made into a cutting, and rooted in spring. That useful plant, *Verbena venosa*, may be cut over to the ground level in autumn, and a light covering of manure put over the roots and left there until March, when it should be lifted, the roots laid in a shallow box, loosely covered with earth, and placed in a temperature of 70°. In a few days abundance of young suckers are ready for taking off, not only as cuttings, but many of them as rooted plants.

Old plants of Petunias are the safest to deal with in winter, and increase is certain from them in spring. Dahlias are easily propagated by means of young shoots which spring from the roots when they are planted amongst droppings or any other loose material on the surface of an inside early Peach or Vine border. The growths should be taken off when they are 2 inches long, and, when severed, they should be put singly into small pots, and remain there until plenty of roots are formed. Coleuses are very subject to damp unless large hard-wooded plants are selected for keeping through the winter. These, although sterile-looking during that season, are quite the opposite when treated with a view to obtaining cuttings in spring. Old plants of Fuchsias, when their leaves are cast, may be set underneath the greenhouse stage, and kept there until the beginning of March, when retention in an advanced Vinery produces many suitable cuttings, which should be dealt with in the propagating pit. Salvias, *Amarantus*, *Ageratums*, and similar plants, may be treated as the Coleus; *Centaureas*, *Cineraria acanthifolia*, *C. maritima*, and *Calceolarias* should be rooted in autumn. Propagate *Alternantheras* in August, so that the plants may be as large as possible by planting-out time. In many places they do not grow freely, so that young spring-rooted plants are too tender and small to begin with. Little wintering room is required for them, however, for twenty cuttings may be stored in a 5-inch pot. In many parts *Gazanias* stand out all winter, with no care. Their propagation may, therefore, be deferred until the end of March, when a large batch of cuttings may be obtained and rooted with very little trouble. The old plants will often

split up and form many small plants with roots attached to them. This plant is no favourite of mine; in dull weather the flowers will not open for weeks, and there is nothing else attractive about it. If old stumps of *Wigandias* have been preserved, they supply plenty of cuttings, which make much better plants than any that will grow from seed. The same remarks apply to *Solanums*, *Abutilon Thompsoni*, and others of its kind. Sweet Alyssum is somewhat long in rooting, but it grows freely when this has taken place; I have often seen bits of it planted out with no roots, and succeed well enough. The soil, in such cases, must be light and sandy. Succulents, of the *Echeveria* type, are too small for bedding out the first year after rooting in the spring. The side shoots of *E. secunda glauca* should be divided in autumn, kept in a moderately warm place throughout the winter, and may be planted in May. Rosette *Sempervivums* require the same treatment, but the hardy sorts must be kept in a cool place. The procumbent kinds of *Sedums* and *Saxifrages* may be divided into tufts in April, and planted out at once into the positions they are to occupy during the summer. *Cerastium tomentosum* should be attended to at the same time in like manner. Some of these plants may be raised from seed, but if a good strain of such as *Lobelia* is obtained, the surest way of retaining it pure is to propagate from cuttings. Pansies and *Violas* should be propagated in October, but old plants do well when divided and planted out about the middle of April; *Mesembryanthemum cordifolium* and other useful members of this family succeed well from spring cuttings, and many other kinds of bedding plants of the annual section are raised from seed.

The cultural treatment as to soil and temperature is much the same as that required by cuttings. When seeds are old or hard they should be soaked in water for a few hours to restore their vitality and freshness before sowing. All plants should be placed in a temperature of from 60° to 70°, and be allowed to make a growth sufficient to form a cutting before propagation is attempted, as the soft young wood roots much more freely than old and hard material. When the first leading cutting is taken off, a double quantity is produced the second time, as two shoots push out from the part stopped. A large cutting is always a ready beginning for a large plant, and this method may be practised where great numbers of plants are not required quickly; but, where the most has to be made of everything, the very smallest shoots may be used, for, if treated kindly, they soon grow out of their miniature state. With most soft-wooded cuttings, it is immaterial whether their bases are cut over directly underneath a joint or not. All cuttings should be put in immediately they are severed from the parent plant. To let them flag is a certain loss of substance which they can ill afford at this time; 5-inch pots are the most convenient for propagation, when larger are used the soil in the centre does not derive so much benefit from the bottom-heat as that in the small size. Where space will allow, the larger-sized cuttings root more readily in small thumb-pots than in any other. Little drainage is needed in cutting-pots, as their occupants are not long in them; they should always be filled with a mixture of which at least half is sand and half some open material. As the pots are filled with cuttings they should have a thorough soaking with water at a temperature of 80°, and be immediately plunged in a bottom-heat of 90°. Where the convenience of a well-heated propagating-house cannot be had, a hotbed with a close-fitting frame and glass sashes placed on the top of it is a very suitable substitute. The bottom-heat should be up to 90° before a single pot is plunged in it; one good bed will retain sufficient heat for two months; in cold or wet weather the whole should be well covered up with mats; a little air should be admitted at the top on fine days when the atmospheric heat exceeds the figure given for the bottom-heat. Boxes, 30 by 18 inches, are the handiest receptacles for nearly all kinds of young newly-rooted plants except Geraniums. These should be well-drained with crocks, the roughest parts of the soil being kept at the bottom. Exhausted Mushroom-bed manure should be freely mixed with the good loam into which newly-rooted plants are to be pricked. This matter is nourishing and sufficiently open for the tender roots to make their way freely; when shifted from their propagating pots they should be placed, but not plunged, in a temperature nearly equal to that

to which they have been accustomed. If bright sunshine prevails at that time they must be shaded. The first and second struck batches are generally benefited by having the tops pinched out; these make excellent cuttings. Each quantity must be "hardened off" to make room for successional, and each and all should be encouraged to make a free and hardy growth before being finally planted out.

J. MUIR.

WOODLAND PLANTS IN VERMONT.

THE following are extracts taken verbatim from a letter received from a correspondent in the State of Vermont, U.S.A. They appear to me so interesting and valuable to cultivators in this country that I hope you will find space for them in your columns. I have received from this gentleman the greater part of the plants named in splendid condition, and expect to see them flower this year, though I am afraid that many of them will not last more than a year or two under the most careful cultivation in this country. I have no doubt, however, that many of them might be naturalised in the woods of the Highlands, and should be glad to send some to any lover of such plants whose estate may furnish the requisite conditions. The beauty of many of them must be seen to be appreciated, though it is beauty that is too little appreciated by gardeners generally.—J. H. ELWES.

By the term "rich woods" we usually mean woodlands occupying strong soil, naturally well drained by being situated on slopes or steeper hillsides. The first growth is largely composed of *Fagus ferruginea*, *Acer saccharinum*, *Tilia americana*, *Juglans cinerea*, &c., whose growth is so dense as to forbid the access of Grasses, and the decay of whose abundant foliage falling each year furnishes a rich bed of black mould. In the conditions thus provided—a cool moist soil, very rich in humus, the fierce heats of our summer sun excluded—a large number of plants flourish, such as *Hepatica acutiloba* (*H. triloba* chooses drier sunnier woods), *Actæa alba*, *Sanguinaria*, *Dicentra*, *Claytonias*, *Arisema triphyllum*, *Asarum*, *Trillium grandiflorum*, *Smilacina racemosa*, *Erythronium americanum*, *Uvularia grandiflora*, &c. Where such woods slope to the north, or where the soil is a little more moist, *Orchis spectabilis*, *Aplectrum hyemale*, *Mitella diphylla*, *Tiarella cordifolia*, *Allium tricoccum*, *Medeola virginica*, *Pyrola secunda* and *elliptica*, *Trillium erectum*, and occasionally *Cypripedium pubescens* thrive. Where the soil of our hills is of a sandy nature, and supports a first growth of *Quercus alba* with a mixture of *Pinus rigida* (sometimes *P. strobus*), and often of *Populus tremuloides*, it is much drier and warmer. Through the sparser growth of trees the sunlight gains greater access, a thinner annual coat of leaves returns to the soil, a little Grass gains a foothold. In such situations we shall hardly look in vain for *Hepatica triloba*, *Polygala pauciflora*, *Gaultheria procumbens*, *Chimaphila umbellata*, *Pyrola rotundifolia*, *P. chlorantha*, *Epigæa repens*, *Habenaria Hookeri*, *Spiranthes gracilis*, *Lilium philadelphicum* and *Coralorhiza multiflora*; and, if the soil is thin, being underlaid with broken rock other than limestone, *Cypripedium acaule* may appear abundant. Still less soil and still more of rock will give us *Aquilegia canadensis*. Cold Hemlock woods, gentle slopes covered with a dense growth of *Abies canadensis*, in the deep shade of which few things besides Mosses can grow, will give us *Habenaria orbiculata*, *Mitchella repens*, *Goodyera repens*, and *pubescens*, *Pyrola elliptica*, often *P. secunda*, *Linnæa borealis*, sometimes *Clintonia borealis*, &c. Rich woods pass into swamps, wet peaty low woodlands. Their sylva is composed of *Ulmus americana*, *Fraxinus sambucifolia*, &c. In these, if not too wet, we find *Trillium cernuum*, *Arisema triphyllum*; in the drier portions, *Trillium grandiflorum*, *Habenaria psycodes*, extending into open low Grass lands; sometimes *Cypripedium spectabile*, *Calla palustris*. When the lowlands are covered with *Abies nigra* and *alba*, *A. balsamea*, *Larix americana*, and *Thuja occidentalis*, they are usually called "Cedar swamps," and are more or less carpeted with *Sphagnum* and other Moss. Here *Clintonia borealis* is the commonest plant. *Trientalis americana*, *Habenaria tridentata*, *Streptopus roseus* and *amplexifolius*, *Smilacina triflora* and *stellata*, *Habenaria dilatata*, *Cypripedium pubescens*, *parviflorum*, *spectabile*, and *aretinum*, *Pyrola rotundifolia* var. *uliginosa*, *Chiogenes hispidula*, *Epigæa repens*, *Linnæa borealis*, are common, and in somewhat open places *Cassandra calyculata*, *Kalmia angustifolia*, *Rhodora canadensis*, &c. These Cedar swamps often run into or border cold *Sphagnum* bogs, the margins of ponds, or old ponds long since filled up by the growth of *Sphagnum*, &c. Very likely a few stunted Spruces (*Abies nigra* or *alba*) are the only trees that have ventured in this unstable soil. Among them and skirting them are *Kalmias*, *Cassandra*, *Myrica Gale*, &c.; but rooting in the decaying *Sphagnum* the following plants find a congenial home:—*Pogonia ophioglossoides*, *Colopogon pulchellus*, *Arethusa bulbosa*, *Habenaria dilatata*, *Microstylis ophioglossoides*, *Listera cordata*, *Sarracenia purpurea*, &c. Thus I

have glanced at nearly every variety of soil and situation in this region. I will now speak of a few plants in particular—*Trillium erythrocarpum* grows abundantly in rich woods of our cooler mountain sides, with it also grows in perfection *T. erectum*; *Lobelia cardinalis*; *Asclepias incarnata*, *Iris versicolor*, *Spiranthes cernua*, and *Habenaria dilatata* prefer open moist Grass lands and do best (the first three certainly) by the side of brooks. None of the *Cypripediums* I think, not even *spectabile* and *aretinum* place their roots where they will be overflowed with water at any time during the year. It may be only a little knoll or a rotting stump, or prostrate log that serves to raise them above the level of high water. That the roots are often frozen I cannot doubt, but probably they are seldom intensely frozen, owing to the protection afforded by the Moss and leaves that cover them. The soil of our Vermont woods freezes very little; it is protected first by the covering of leaves, then by a coat of snow, which, in the shade of the trees, leafless though they are, seldom melts during our winter thaws. The roots of *Orchis spectabilis* often have a good deal of water during the entire year; for example, near swamps through which some rill soaks down through the peaty soil is a favourite situation for this plant; but the crown of the plant is always, I think, raised a few inches above the water level. With respect to *Sarracenia*s I have to tell you that *purpurea* is very abundant here. It grows in bogs rooting in *Sphagnum* or morasses, and, with the contents of its pitchers, is hard frozen during winter. Often it must be imbedded in solid ice, and is thawed and frozen several times during winter; yet, it is so hardy that all this severe treatment injures it not the least. *Sarracenia flava*, a native of the Southern States, must be able to endure several degrees of frost.

SWEET-SCENTED FLOWERS.

THIRTY years ago I published a small volume on the sweet-scented flowers and shrubs cultivated in the gardens of Great Britain. The volume has long been out of print; but, as recent investigations have given a new interest to the subject, it seemed worth while to make a classified list of the species mentioned in that forgotten work which were there partly arranged in an alphabetical manner. It will be observed that the catalogue is limited in several ways. It does not include stove or greenhouse plants, nor wild plants which are never cultivated, nor agricultural plants, nor pot-herbs. A few species are included in it whose scent resides in the leaves and not in the flowers because it was intended for the help of amateur gardeners. Opinions may differ as to the sweetness of some of the odours, but I give the list entire, with the nomenclature of that period. It was, no doubt, imperfect even at that time, and probably many more species might now be added by anyone familiar with the gardens of the present day. There can scarcely be less than 5,000 species, hardy and half-hardy, cultivated in English gardens, and 217, which is the number in this list, seems to be but a small proportion of fragrant ones. The following observations suggest themselves in looking through the list:—That scent is associated with flowers of all colours; that, nevertheless, the order *Campanulaceæ* and the genus *Gentiana* are unrepresented, and that the flowers of these groups are chiefly blue; that scarcely any order can claim fragrance as a universal character; that in many genera one species only will be fragrant, while all the rest are scentless; that by cultivation and hybridisation fragrant varieties may be developed from scentless stocks.

[The preceding list, furnished by a correspondent of the "Gardeners' Chronicle," is very imperfect. Hundreds of hardy plants alone might be added to it. With reference to the remarks on the Gentian family, we have certainly found *G. verna* frequently with a distinctly agreeable odour.]

Layering Clematis Jackmanni.—A few days ago I was lifting layers of *Clematis Jackmanni* which were buried about 5 inches deep a year ago. They had all rooted well, and, if potted now, will make fine plants for this year's flowering. Examine the roots very carefully, and if you can manage to cut off an eye with the least bit of root attached to it, put it into heat, and by next autumn you will have a capital plant for outdoor planting. The plants which I thus obtained last spring are almost as fine now as their parents. All the *Jackmanni* section will easily multiply in this way, and I cannot understand why this system is not more used than it is by nurserymen. Could any plant yield such a return as this? You can buy good plants at one shilling apiece, layer them, and make, in a year's time, two or three good plants from each, besides having your original plant in hand, and any others you may obtain from rootlets. Two plants (two-year-olds) have produced together twelve fine plants, and all the result of half-an-hour's labour. At Sir John Majoribanks, at Coldstream, I have seen flowers of *Clematis Jackmanni* on a north wall, in a wet peaty soil, more than 6 inches across, and much deeper in colour than if exposed to the full rays of the sun. It is generally finer on a north wall than in any other situation, provided it has a moist vegetable soil to root into, and plenty of it. Deeper and richer in colour is *Clematis velutina purpurea*, one of Messrs. Jackman's latest seedlings.—FRANK MILLS.

THE FRUIT GARDEN.

VINES AT DRUMLANRIG.

I HAVE sent you a piece of wood of the Bowood Muscat, cut from the top of a 22-foot rod at Drumlanrig, last November.* It is, as you will see, as firm and hard as a piece of ebony. Not only this variety, but the whole of the young Vines there are in unusually good condition, not one small or imperfect cane being amongst them. The house in which the Muscat grows is a very commodious one; its rafters are 22 feet in length, and it is kept at a temperature suitable for Black Hamburgs. It contains, besides the Muscat, Hamburgs of different kinds, Buckland Sweetwater, Foster's Seedling, Black Alicante, Duchess of Buccleuch, and Mrs. Pince, none of which are inferior to the sample sent. These were all propagated from eyes, and planted out at midsummer, 1873. The growth which they made from that time until the end of the season was most satisfactory. They were cut back to within 2 feet of the bottom in the spring of 1874, and their progress since that time has been all that could be desired. In November last, numbers of supernumerary rods of Gros Colman were in fruit in this house. These, to give the bottom growth of the permanent canes full justice, had been disbudded to within 7 or 8 feet of the top, and when I saw them they were bearing bunches that would average about 3 lbs. each, and I counted nine of such bunches on the 7 feet of cropped space. A house next to the one just described is planted with Muscats, Trebbiano, Raisin de Calabria, Syrian, Gros Guillaume, and Gros Colman. Duke of Buccleuch had fruited excellently as a supernumerary in this house, and permanent Vines of it formed no exception to the others. I had the curiosity to measure the girth of a rod of Trebbiano, and found it to be 4½ inches at a foot above the ground. About a foot further up it branched into three leaders, 22 feet each in length. This Vine was struck from an eye and planted, like the others, in 1873. The fruit of Syrian, Trebbiano, and Raisin de Calabria, was excellent, not only in flavour, but in size of bunch and berry. They were, in short, model bunches, compared with those one often sees after the "damping" to which Grapes are subjected in October and November. It is not, I know, unusual for a Vine to make 22 feet of young wood in a season, but it is an uncommon occurrence for such growth to be equal in thickness at top and bottom in a length of 22 feet, and this was the case with the Vines in question. This growth, too, was thoroughly ripened, a difficult matter with many. Every rod, lateral growth, and leaf-stem was ripe nut-brown and the foliage was still green; this has been effected by care and attention alone, as Dumfriesshire is one of the wettest counties in Scotland, and sunshine, which is generally considered indispensable, has had but little to do with the result. These Vines replaced those which were destroyed by the *Phylloxera*. The borders in which they grow have been carefully made, but the soil is not different from that in which Vines are usually grown. M.

PEAR SYNONYMS.

IN reply to your correspondent, "B. S.," allow me to mention that the Soldat Laboureur is a variety which was obtained by Major Espéren, a well-known Belgian raiser. The name Soldat D'Espéren, which has also been given to this variety, must be considered as an abbreviation of Soldat Laboureur Espéren. Orpheline D'Enghien, Beurré Deschamps, Beurré d'Arenberg (in Belgium) are synonyms. It is possible, however, that a slight dissimilarity may exist between the Beurré d'Arenberg (in Belgium) and the Beurré Deschamps and Orpheline d'Enghien, but it is not sufficient to constitute different varieties. This, at least, was the opinion of the French Pomological Congress. Glou Morceau, Beurré d'Arenberg (in France), and Beurré d'Hardenpont are only one and the same variety. The last name is that which has prevailed with the French Pomological Congress, and it is necessary to remark that, by the adoption of this title and of that of Orpheline d'Enghien, the various kinds of Beurré d'Arenberg have been made to disappear, and henceforth any further confusion between two very distinct varieties, which had previously but a single name, is rendered impossible. Colmar d'Hiver is an entirely different fruit from the preceding—a fact which has already been pointed out in THE GARDEN. I am happy to have been so well understood by "B. S.," who has perfectly recognised the circumstance that the seven names quoted by him in reality apply to four varieties. As regards the Beurré Spence, it is far from being the same as Urbaniste, but it is a synonym of Flemish Beauty (Belle de Flandre in French), and also of the Beurré Davy, the Beurré de Bourgogne, &c. Our Jargonelle, in fact, differs from the Pear which bears that name on the other side of the district, and which is here called Epargne Cueillette, and perhaps more frequently Cuisse Madame. I am also at a loss to understand why in England you give the name of

Royal Muscadine to our favourite Chasselas de Fontainebleau, a variety which, by-the-bye, originally came from Cahars in Languedoc. I must confess that, in publishing "The Fruit to Cultivate," I had in view the kinds best adapted to the climate of Belgium and France; but I also believe, with my friend Mr. W. Ingram, that at least the majority of the varieties of Pears that I have recommended would be valuable for cultivation in England. If the Beurré Superfin and the Beurré Hardy are fruits which at Belvoir ripen too quickly, I can only say that here I have never observed that fact. Beurré d'Anjou is a name that ought to be got rid of. The fruit to which it is applied is the Ne Plus Meuris, or, more correctly, the Ne Plus Ultra Meuris, an excellent Pear obtained by Van Mons, and named after his gardener Meuris. I know that Mr. Rivers at one time cultivated under the name of Ne Plus Meuris a different Pear—a smaller fruit, and one that ripened later. Passe Colmar is, without doubt, an excellent Pear, but it is one which does not seem to thrive in some parts of England. I have felt much satisfaction at seeing the Olivier de Serres praised; it is unquestionably a fruit that will prove good in all respects, and is destined to be grown on a large scale. I have not had the opportunity of knowing the Victoria and Prince Consort Pears of Mr. Huyshe. Knight's Monarch does not do so well here as in England, added to which the tree is a bad grower, at least when grafted on the Quince. I regret that I am unable to speak in terms of praise of Beurré Rance. Too often the late ripening of this fruit constitutes its only merit. I have rarely eaten any of really superior quality. On an espalier, even, it leaves much to be desired.

F. JAMIN.

COST OF PRODUCING HOME-GROWN POT VINES.

YOUR correspondent, "Mr. Muir," says (p. 45), that pot Vines can be bought both better and cheaper from the trade than they can be grown at home. Allow me to inform him that I have grown pot Vines for many years in considerable quantity—sometimes disposing of a few surplus plants to the trade, for which I can always get the highest price, and the cost of production is about 3s. each at the most, including the price of the pot. I set a small house apart for the purpose, airing it in a systematic way, and I have never been able to buy such Vines, as regards vigour and earliness, as I can grow myself. What I do others no doubt can do as well, and do so frequently to my knowledge. "If growers for the trade" can grow pot Vines for 5s. or 6s. a-piece, according to vigour, and get a profit out of them, one would imagine that the private grower could save a trifle by growing his own. I know one grower who produces about 2,000 pot plants every year for seedsmen, who only sell them, and both apparently thrive on the business. I know one firm which buys about 700 plants annually from this raiser, and sells them for from 7s. 6d. to 10s. 6d. and 12s. each. I will not say that good Vines are not to be had from nurserymen, but I am sufficiently acquainted with the trade to know that your correspondent's statements are an exaggeration in this matter. It is new to me to learn that "skilful Grape growers" generally fail, "year after year, in growing pot Vines." I have had more to do with Vine growing than anything else, for nearly thirty years, and I never knew a "skilful Grape grower" fail to grow pot Vines with ease and little expense, when he found it necessary to do so, and set about it in a practical way.

VITIS.

Mr. Muir, in recommending bought pot Vines, speaks rather disparagingly of the attempts of gardeners in private establishments to grow their own Vines, and I very much question his statement that "skilful Grape-growers fail to grow their own pot Vines successfully." I know many gardeners who would consider buying ready-grown pot Vines little better than buying ready-grown Grapes, and many more in small places who actually have not the means allowed them to buy Vines, and are yet expected to cut Grapes from pot Vines in April and May. As to the "extra care and attention" given to pot Vines in nursery establishments, it is only where a speciality is made of their culture that this happens; and on Mr. Muir's own showing, in spite of the care and attention given them, and the economical way in which they are grown by the trade, a high price is demanded, or else one must put up with a bad article. I do not object to Mr. Muir praising the excellence of trade produce, but I certainly think that he would have rendered more real service to horticulture had he told us exactly how pot Vines are grown by the trade instead of disparaging the well-meaning efforts of those who, by either choice or necessity, grow their own canes. Let us look at the matter in another light. Pot Vines are "readily obtainable" only when one has the money to buy them. Supposing I wanted to buy, say, two dozen fruiting canes. They must be strong, short-jointed, and well ripened, and for these I must pay at least 12s. 6d. and perhaps 15s. each,

equal £14 8s. or £18, as the case may be, to which must be added £3 at least for carriage and packing; this gives £17 8s. or £21, besides the chance of introducing that terrible pest which I happen to know has quite recently ruined some of the best Vines in the country, in spite of the utmost caution to prevent its introduction, and the most strenuous efforts to eradicate it immediately its presence was discovered. I will say nothing of my own Vines, but I am at liberty to speak of the productions of other private gardeners, who grow pot Vines equal to any ever sent out by the trade. Mr. Gilbert, at Burghley, showed me a splendid lot of canes last year, and there are but few growers, with whom I am acquainted, who cut better Grapes from pot Vines than he does, year after year. Another excellent grower, Mr. Mackellar, when at Elvaston Castle, grew his own Vines from eyes, and he has cut clusters of Black Hamburgs from pot Vines, weighing from 1 to 3 pounds each, the whole crop averaging considerably over a pound each bunch; facts which I merely mention to convince Mr. Muir that at least some private growers can grow pot Vines equal to those sent out by the trade.

Whalley Range.

GRAPES TRAVELLING WITHOUT PACKING MATERIAL.

AFTER the care and attention required to grow good Grapes, well-coloured, with a good bloom on them, the next consideration, is how shall they be packed in order to preserve the bloom from being rubbed off them. Different gardeners have different ways of packing. Some sixteen or eighteen years ago wrapping each bunch in tissue-paper, and packing them with paper shavings was recommended, a practice which I have seen adopted a few months back. No doubt Grapes packed in this way carry well, but most of the bloom (which is so much admired on the dinner-table) is left in the packing material. In your paper (see p. 30) a correspondent writes to say, that Grapes sent from Clovenfords to London in baskets, without packing material, arrived at Covent Garden in as fine condition as if they had never been packed. This is surely saying too much, because, if Grapes rub against one another, the bloom will, as a matter of course, be damaged more or less; but still, in my opinion, no packing is best. An amateur, however, who wishes to send 8 or 12 pounds to a friend, would find it both expensive and inconvenient in many cases to use baskets. I send a great many Grapes to London and other distant places, and the condition in which they arrive gives perfect satisfaction. First of all, our boxes are all made of $\frac{3}{4}$ inch sawn boards, and for all ordinary-sized bunches (that is, from the smallest to those of 1½ lbs. weight) the boxes are constructed with a depth of 5½ inches. I allow 16 square inches to every pound, except for more than 12 lbs. weight, when I allow only 15 square inches to a pound, for the larger the box the less room they take; for instance, if I receive an order for 6 lbs. of Grapes, I multiply 16 by 6, which will require a box 12 by 8 inches, or if for 12 lbs., a box 15 by 12 inches and 5½ inches deep. For the larger sorts, as Barbarossas, Alicantes, &c., we make the boxes according to size, and pack the Grapes on their sides. I first cover the bottom of the box with a depth of about ½ inch of soft hay, then lay a sheet of strong white cap-paper over it, and a piece round the sides, weigh the box, take it to the Vinery, and place it firmly on one end, at an angle of about 75°. I next lay a bunch in each corner, and a little discretion will be required to cut them of a size that will just fit, and pack the others tight, as a bunch should never be moved after being once in position; a little practice, however, will soon make this easy. Continue in this way till the box is full, when the Grapes should be half an inch from the lid, when closed, and the stalks being 2 or 3 inches longer, act as a spring against the lid when shut, thus obviating oscillation. Ordinary-sized bunches are placed as much as possible on end, as they can be thus packed closer together than in any other way.

JAMES SMITH.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Irrigating Vines.—A Californian correspondent states that he irrigates his Vineyard by covering the ground with water when the Muscats are about the size of small Peas. If irrigated earlier the fruit is apt to drop; if later, the soil remains too wet at the time of ripening, and causes mildew. He adds:—On some portions that I did not irrigate I raised 20 lbs. of first crop and 50 lbs. of second crop per Vine. But where I irrigated the yield was much larger—so much so that I determined always to irrigate in the future. I can raise on the larger Vines 50 lbs. average at the two crops. This will make 17 lbs. of raisins, which at present prices will sell for 8s. I set 500 Vines per acre, which gives £200 per acre for Muscat raisins.

Furnishing a South-west Wall with Fruit Trees.—At line eight of the paragraph (see p. 45) having reference to this subject, for "at first independently of the Vines," read "at first independently of the wires."—B. S.

THE KITCHEN GARDEN.

MUSHROOMS AND MUSHROOM-HOUSES.

THE importance of plenty of Mushrooms, where a large establishment has to be supplied with them, can scarcely be over-rated. To the Mushroom-house, therefore, much attention must be devoted; but it sometimes happens that a house built expressly for the growth of Mushrooms is less efficient than some shed or out-building that is occupied in that way merely because nothing better is available. This may be accounted for by the builder, unacquainted with the conditions under which the Mushroom will grow, providing, as he often does, ample light and ventilation, when these should invariably be carefully excluded. If we consider the fact that Mushrooms spring up most abundantly with us in autumn on old pasture land, especially after hot summers, while the earth retains its heat and the nights begin to lengthen and become cool and highly charged with atmospheric moisture, we shall have some guide to their treatment under artificial conditions. Without this kind of atmosphere, however carefully the beds are made and attended to, the results will not be satisfactory, more especially if much fire-heat is needed to keep the temperature up to its proper height. The best of all situations, when available, in which to grow Mushrooms, are underground caves, such as supply the Paris markets with such vast quantities. These contain a still, humid atmosphere, and where a succession of beds is constantly in course of formation, the air becomes charged with ammonia, which greatly assists the growth of the young Mushrooms. When such situations are not available, the best plan for securing the required amount of humidity in the air of the Mushroom-house or shed is to keep a heap of fresh fermenting manure in it, and frequently turn it over. This will be found superior in effect to any evaporating trough or steaming apparatus. A long close-roofed shed here is the best place for the Mushroom-beds I ever met with, although it was not built for that purpose. The reason is that a large tank for heating water for horticultural purposes is fixed at the end of it over a tubular boiler. This gives off so much steam that the shed is useless for storing anything that will either rot or rust. The beds in this shed never require mulching or watering, and continue hearty for an unusual length of time. The method of preparing Mushroom-beds has been so often described in your columns that I need not enter upon it further than to say that we mix a good quantity of fresh loam with the stable manure, which moderates the heat, and consequently makes it more lasting. A temperature in the beds of 80° at spawning

time, and an air-heat of 55°, we find to suit admirably. Another and important point is a good clayey loam with which to earth the beds. This should be beaten down as hard as mallet and spade can make it, and wetted so that a smooth spade will slide over it. It is often stated that any sort of soil will do for covering the beds, and this to a certain extent is true, inasmuch as, if all other circumstances are favourable, some Mushrooms will be produced; but the produce will be neither so good in quality nor so lasting as when a rich loam is employed. One of the many advantages of a firm surface to the beds is that the Mushrooms form on the surface, and are easily gathered without injury to the bed; but with soil of a loose texture the

majority of the Mushrooms will form on the manure, and cannot be gathered without disturbing the growth of many of the successional ones.

J. GROOM.

Cucumis metuliferus.

ORNAMENTAL GOURDS.

IN warmer latitudes, Gourds are common in all gardens. It is different, however, in this and other temperate climates, where creeping plants of rapid growth and large development, cultivated for ornament, are so limited in number, but none of them ought to be rejected if they can, either by their fruit, flowers, or foliage, serve to ornament trellis-work, or cover walls or arbours. For this purpose nearly all Gourds appear well adapted, and deserve to be much more frequently used, and under more varied conditions, than is now generally the case. Our engraving represents one of the most singular of Cucurbits—one having oblong fruits set with stout horn-like protuberances. Its fine lobed foliage is heart-shaped at the base, and of a fresh green colour. The main essentials, as regards culture, are a deep rich soil, a warm sunny position sheltered from high winds, and a plentiful supply of water or liquid manure during hot dry weather.

How to Clean Gravel Walks with Salt.—To maintain garden walks in the best order, and free from weeds, is often a difficult task, especially where the means and assistance at the command of the gardener are inadequate to the extent of ground allotted to his charge. Walks, moreover, to be really smooth and pleasant to walk upon require either to be hand-picked or salted, and never touched by hoe or rake, which only bring the gravel to the sur-

face, and leave the binding materials beneath. The plan we practise here is so simple and effectual, that I will try to explain it. Instead of boiling water for melting the salt and applying it hot, as is done by Mr. Fleming's method, we simply put the salt into cold water, at the rate of $\frac{1}{2}$ lb. to the gallon of water. The water cask we use holds upwards of a hogshhead, and 28 lb. of salt is put into it at one time with 56 gallons of water; while one man fills in the water another is stirring the salt, and by the time the proper quantity is in, the salt has melted, and the salted water is ready to move away to where it is to be applied. The two men, being each provided with a large watering-can having on it a wide-spreading rose, commence watering by facing the centre of the walk,

and, keeping their hands low, they move along the sides for a short distance first, so as not to allow any of the water to be nearer the Box-edging or Grass-verge than about 4 inches. They then turn into the centre of the walk, and apply only sufficient to make it wet all over the surface. This small quantity soon dries up, and leaves the walk with a whitish appearance, which remains until rain falls to wash it down; and then, as soon as it becomes dry, it assumes a bright and clean appearance, and will keep so throughout the season. The great desideratum is, however, to make the application only when the walks are dry, and the weather clear and hot. Any time during the month of April is a suitable period. I prefer coarse salt to fine. What we use is the same as the fish-curers make use of. The cost here is £2 per ton.—J. WEBSTER, in "The Florist."

POTATOES GROWN IN 1874 AT CHISWICK.

By A. F. BARRON.

AFTER the full and comprehensive trial of Potatoes made by the fruit and vegetable committee in 1873, it was not this season deemed necessary to continue the cultivation of so complete a collection. The trial has, therefore, been confined to sorts which were not cultivated last season, or which were but imperfectly represented. Several of the leading types have been grown for comparison. The collection, about 158 in number, was planted on the 23rd of March on well-trenched and manured ground. The sets were in most cases put in whole, in lines, 3 feet apart, and about 20 inches between each set. The plants came up well, and looked promising, but were cut down by frost repeatedly. This caused a great number of stems to perish, and, combined with the exceeding dryness of the summer, tended to make the crop small, although it was of excellent quality. The disease did not make its appearance until the 6th of August, and then the tubers were affected, whilst no trace of it could be found on the haulm. Several varieties suffered severely, especially some of the American sorts, Lapstones and Red-skinned Flour-ball. In 1873 the Regent class suffered most severely, and the Red-skinned Flour-ball was almost free. This season the result is exactly the reverse. Many of the stools had a dressing of Amies' patent chemical manures, which certainly tended to increase the crop. The committee examined the Potatoes, whilst growing, four times, and awarded five first-class certificates. The number of assumed distinct varieties examined amounts to 280, not including some sixty unnamed seedlings. This formidable list has been reduced by the detection of synonyms to 150 varieties, which have been described, and are probably distinct. In the following list the same arrangement is adopted as in the report of last year (see Vol. V., p. 103). This may be referred to for the descriptions of the kinds which were tried then:—

Series I.—Skin White or Straw-coloured.

§ 1. Long or Kidney-shaped.

Ashleaf Kidney.—Synonyms, Marjolin, Oakleaf, Duckstone, Sandringham, Kidney (Minier & Co.), Early White Long Kidney (Veitch), and Cooling's Improved Ashleaf (Cooling).

Mona's Pride.—Haulm and general characters of plant same as in Ashleaf Kidney; tuber, short, rather broad and flat. An excellent variety.

Kentish Ashleaf Kidney.—Synonyms, Veitch's Improved, Cave's Seedling, Cambridgeshire Kidney, Nutbrown, Alma Kidney, Early May, Benson's Seedling, Shepherd's Kidney, Reynard, Nonsuch, Tory, Conqueror, Mona's Pride, Champion, Early Ranelagh, Laing's First Crop, Stillyan's Kidney, Gillman's Early Pebble (Gillman), Welbeck Seedling (Tillery), and Champion (Harrison & Sons).—This, in 1873, was considered distant from Myatt's Ashleaf, on account of the latter being berry-bearing, whilst the Kentish was not so. It has, however, this season produced flowers; so it is doubtful whether any distinctions really exist, further than what may be obtained by change of seed.

Myatt's Ashleaf Kidney.—Synonyms, Rivers's Royal Ashleaf, Sandringham Kidney, Myatt's Prolific, Gloucestershire Kidney, Derbyshire Prize Taker, and Lee's Hammersmith Kidney.

Bonnemain (Carter).—A very dwarf slender-haulmed variety of Kentish Ashleaf.

Toddington Kidney (Horley).—A later, more robust, and very productive form of the Kentish Ashleaf.

Advancer (Bell & Thorpe).—Haulm, slender, compact, 12 to 15 inches long; stem, pale green; leaflets, small, pointed, pale green; flowers, very rare; tuber, short, flat, kidney-shaped; eyes, full; skin, smooth, pale, straw-coloured; flesh, pale, firm; moderate cropper; first early. Commended.

Jackson's Improved.—Haulm, spreading, 18 inches long; leaves, rugose, deep green. Growing later than the Kentish Ashleaf.

Cattell's Reliance (Cattell).—Haulm, moderately robust, spreading, 2 feet 6 inches in length; stem, pale green; leaflets, small, rugose, pale green; flowers, purple, sterile; tuber, medium-sized, of the general appearance of the Lapstone; eyes, few and small; flesh, white, very firm, of good quality. Ripe, September 2. Second early.

Cattell's Eclipse (Cattell).—Haulm, moderately vigorous, spreading, about 3 feet in length; stem, pale green; leaflets, rugose, pale green;

flowers, light purple, rare; tuber, medium sized, in shape like the Lapstone; skin, rough, pale straw; flesh, white, firm; quality excellent. A fine second early. First-class certificate.

Prince of Wales.—Synonym, The Barber (Dean).

Silverskin Kidney (Dean).—Synonyms, Sear's Seedling (Horley); Lady Abbess (Sutton); haulm, robust, spreading; 2 feet in length; stem, pale green; leaflets, small, rugose, pointed, pale green; flowers, large and handsome, white, abundant, fertile; tuber, medium-sized, long-cylindrical, rather coarse; eyes, few, scattered, small, deeply-sunken; skin, rough, pale straw; flesh, firm, white. A moderate cropper. Second early.

Waterloo Kidney (Dean).—Haulm somewhat resembling Myatt's Ashleaf.

Dawe's Matchless.—Synonyms, Webb's Imperial, Wormsley, Bryanstone Kidney (Veitch), and Manning's Kidney. —Haulm, strong, robust, of somewhat spreading growth, about 2 feet 6 inches high.

Excelsior Kidney (Dean).—A more erect-growing and much-improved form of Dawe's Matchless, producing a larger and finer sample. Extra fine quality. First-class certificate, 1873.

Queen of Canada (Stone).—A very large form of Dawe's Matchless.

Lapstone.—Synonyms, Haigh's Seedling, Cobbler's Lapstone, Almond's Yorkshire Hero, Pebble White, Headley's Nonpareil, Huntingdon Kidney, Yorkshire Hero, Perfection, Rixton Pippin, Ashtop Fluke, Welbeck White, Second Early, Ne Plus Ultra (Farquhar), and Early Kidney (Veitch).

Confederate (Veitch).—Haulm, robust, spreading, 2 feet in length; stem, tinged purple; leaflets, small, pointed, rugose, brightly green; flowers, abundant, pale lavender; tuber, very large, long, flattened, somewhat kidney-shaped; surface, smooth, even; eyes, few, small, full; skin a little rough, pale straw; flesh, firm, white. A heavy cropper and very handsome. Second early.

New Englander (Hooper).—Haulm, robust, erect, about 2 feet 6 inches in height; stem, pale green; leaflets, large, pale green; flowers, large, white, very abundant; tuber, large, long cylindrical; eyes, numerous, scattered over entire surface, small and deeply sunken; skin, smooth pale; flesh, firm, white. Moderate cropper. A very coarse looking Potato. The leaves decay from off the stem early in a singular manner, the stem remaining erect until it crumbles all away. Second early.

Model (Bell & Thorpe).—Quality excellent.

Shiner (Harrison & Sons).—Haulm, of the Regent character of growth, 2 feet 6 inches long; stem, tinged purple; leaflets, dark green, rugose; flowers, bluish-white, fertile; tuber, large, broad, flat, of the Fluke character; eyes, small, full; skin, pale straw-coloured, a little rough; flesh, close, yellow. A great cropper and handsome. General season.

§ 2. Half long.

President (Dean).—Haulm, slender, spreading, 2 feet long; stem, tinged with purple; leaflets, small, rugose, pointed; flowers, shaded, lilac; tuber, short, flat, very even and regularly formed; eyes, small, few; skin, pale straw-coloured, slightly rough; flesh, firm, white; very handsome. Moderate cropper. Second early Potato. Excellent quality.

Cooling's Early Favourite (Cooling).—Synonyms, Sutton's Early Defiance Kidney (Sutton), Flower's Early Wide Awake (Flower), The Shiner (Dean).—Haulm, robust, spreading, 21 inches long; stem, slightly tinged purple; leaflets, large, of the general appearance of Kentish Ashleaf; flowers very large, abundant, of a bluish colour; tuber, medium-sized kidney, hollow at crown end; eyes, situate on crown and on knobby protuberances like the Ashleaf; skin, clear straw-coloured, very handsome; flesh, close, pale straw-coloured. A very heavy cropper of inferior quality. Second early.

Cattell's Intermediate (Cattell).—Haulm, strong, vigorous, 3 feet 3 inches long; stem, pale green; leaflets, rugose, pale green; flowers, white tinged purple, fertile; tuber, medium, greatly resembling Paterson's Victoria, flattened, broader at one end; skin, rough, pale straw-coloured; flesh, firm, white. Mid season.

Bresee's Climax.—Synonyms, Gravenstein, Coppermine, Climax. Haulm, moderately strong, about 1½ feet long; stem, light green, spreading, branching. First-class certificate, 1873.

Snowflake (American) (Carter & Co.; Hooper & Co.; Bliss & Sons).—Haulm, moderately robust, compact, ripening early, 2 feet long; stem, pale green; leaflets, large, broad, pointed, very pale green; flowers, seldom opening; tuber, large, long-ovate, tapering towards the crown; very even and regular; eyes, small, almost level with the surface of the tuber; skin, pale, straw-coloured, rough; flesh, white, of good quality; a very heavy cropper. Early, and one of the most handsome of Potatoes.

Bresee's Prolific.—Synonyms, Brown's Prolific Kidney; Sutton's King (Farquhar).

Dwarf White (Bliss & Sons).—Haulm, compact, about 12 inches long, ripening off very early; stem, pale green; leaflets, broad, flat, very pale green; flowers, not opening; tuber, medium size, half-round, flat; surface, uneven; eyes, large, deeply sunken near crown end; skin, smooth, very clear, pale straw-coloured; flesh, firm, white, of excellent quality for early use; moderate cropper. One of the very earliest of Potatoes. First-class certificate, 1874.

Dourie Hall Favourite (Montagu).—Haulm, robust of Regent type, about 3 feet in length; stem, pale green; leaflets, large, broad, pale green; flowers, bluish-white, sterile; tubers, large, half-round, sometimes long; eyes, few; skin, a little rough, pale straw-coloured; flesh white, firm. Good cropper. Mid Season. Very distinct.

Paterson's Victoria.

Cattell's Late Nonpareil (Cattell).—This resembles Paterson's Victoria.

§ 3. *Round.*

Regents.—Synonyms, York Regent, Mitchell's Prolific, Early Oxford, Pink-eyed Regent, Rintoul's White Don, Scotch Don, Rusty Coat, Rough Jacket, Early Chinese (Veitch), Early White, Round Erfurt (Veitch), Early Don, Gryffe Castle (Harrison).—The above are varieties of the true Regent Potato, varying somewhat in point of earliness, and in cropping qualities. This, it is believed, is more due to change of soil than any permanent distinction. This is, perhaps, the best and most generally useful Potato in cultivation.

Dalmahoy.—Synonym, Goldfinder.

Walker's Early.

Rector of Woodstock (Fenn).—First-class certificate, 1872.

Fenn's Early Market.—First-class certificate, 1873.

Henderson's Prolific (Farquhar).—Haulm, spreading, moderately robust, 2 feet 6 inches long; stem, pale green; leaflets, pale green, rugose, resembling those of a Regent; flowers, pale lavender, fertile tuber, below medium size, round; form, even, regular; eyes, full; skin, clear, slightly rough; flesh, pale straw-coloured. A good useful early; Potato. Great cropper.

Tullinamoult (Farquhar).—Haulm, moderately robust, 21 inches long; stem, tinged purple; leaflets, small, crumpled, withering early; flowers, abundant, purplish-white, fertile; tuber, below medium size, round, flattened at crown end; eyes, rather deeply sunken; skin, smooth, pale; flesh, pale-straw coloured, firm. Moderately prolific. Second early.

Early Dimmisk (Farquhar).—Haulm, gross, spreading, 2 feet 6 inches long; stem, pale green; leaflets, large, broad, pale green; flowers do not open; tubers, very large, about five or six produced at each root, of form somewhat irregular, rounded, hollowed at stalk; eyes, small, full; skin, rather rough, pale; flesh, white, firm, of excellent quality. Second early. First-class certificate, 1874.

Irish White (McGann).—Haulm, like that of strong Regent; flowers, not opening; tube, medium round; eyes, small, very deeply set, giving the tubers a nobbly appearance; skin, pale, smooth; flesh, white, firm. A fair cropper. Late second early. A hardy vigorous Potato.

White Peach-blossom.—Synonym, Peach Blow (Carter).

Lockloy's Perfection (Burslem).—Haulm, robust, spreading, 3 feet long; stem, pale green; leaflets, rugose; flowers not opening; tuber, large, rounded, much flattened; eyes, chiefly situate at the crown, deeply sunken; skin, rather rough, pale; flesh, white, firm. A fair cropper. Mid season. A coarse looking Potato.

Prize of Holland (Veitch).—Haulm, moderately robust, 27 inches long; stem, pale green; leaflets, small, rugose, green; flowers, lavender and white; tuber, small, round; eyes, small; skin, nearly smooth, pale straw-coloured; flesh, yellow-coloured, small, and very inferior. Second early.

Series II.—Skin Red.

§ 1. *Long or Kidney-shaped.*

American Late Rose.—Synonym, American Pale Rose.—First-class certificate, 1873.

American Early Rose.

Extra Early Vermont (Bliss & Sons).—First-class certificate, 1873.

Rice's Seedling (Farquhar).—Haulm, very robust and gross, 2½ feet long; stem, green; leaflets, bright green, pointed; tuber, large, long, rounded, producing very numerous small ones, very uneven; eyes, small, deep, scattered; skin, rough, faintly shaded pink; flesh, white, coarse. A very coarse sort.

Bountiful (Fenn).—First-class certificate, 1874.

Early Red Kidney (Dean).—Haulm, slender, spreading 18 inches long; stem, pale green; leaflets, small, pale green, ripening early; tuber, long, slender, of a true kidney shape; eyes, few, small, full; skin, smooth, pale red; flesh, close, yellow. An early sort. Great cropper, and worthless.

§ 2. *Round.*

Red Emperor.—Synonym, Carter's Main Crop.

Vermont Beauty (Bliss & Sons).—Synonym, Brownell's Beauty. First-class certificate, 1873.

Welbeck Red (Tillery).—Haulm, very robust, 4 to 5 feet long; stem, tinged red, leaflets, rather small, pointed, rugose, light green; flowers, purplish-white, fertile; tuber, medium; form, even, round; eyes, small, deeply-placed; skin, rough, pale red; flesh, white, coarse-grained, good for late use. A great cropper. Was raised from Scarlet Prolific. Late.

Rufus (Harrison).—Haulm, very robust and gross, 3 feet 6 inches long; stem, tinged red; leaflets, large, pale green; grows very late; flowers, white, abundant, fertile; tuber, medium-sized; form, regular, rounded; eyes, small, full; skin, very rough, deep red; flesh, close, yellow. A handsome Potato, and a great cropper, but too coarse. Late.

Series III.—Skin Purple or Blue.

§ 1. *Long or Kidney-shaped.*

Precoce de Remy (Veitch).—Haulm, straggling, slender, 2 feet 6 inches long; stem, reddish; leaflets, small, rugose, deep green; flowers, not opening; tuber, small, true kidney-shaped; form, very even; eyes, small, skin dull, purplish-red; flesh, close, yellow. A poor cropper, and very worthless. Second early.

True Blue (Dean).—Haulm, slender, spreading, 18 inches long; stem, reddish; leaflets, small, rugose, deep green; flowers, white,

fertile; tuber, long, narrow, kidney-shaped; form, even; eyes, small, level with surface; skin, rather rough, deep purple; flesh, white, firm. Handsome. A moderate cropper. Second early.

Purple Ashleaf (Farquhar).—Synonym, Stafford Hall (Farquhar).—Haulm, moderately strong, resembling Kentish Ashleaf, spreading, 18 inches long; stem, tinged purple; leaflets, small, rugose, pale green; flowers, not opening; tuber, above medium size, long, flat; form, very even, kidney-shaped; eyes, very small, full; skin, smooth, reddish-purple; flesh, pale, with a dark streak through, close. A handsome-looking Potato, and a fair cropper. Second-rate quality. Early.

§ 2. *Round.*

Compton Surprise (Bliss & Sons).—Haulm, very robust and gross, 18 inches long; ripens off early; stem, green, tinged with red; leaflets, very large, broad, pale green; flowers, white, sterile; tubers, large, long, flattened, coarse in appearance; eyes, numerous, very deep, scattered over entire surface; skin, smooth, dark purple; flesh, white, firm. A moderate cropper. Mid-season.

Scotch Blue.—Synonyms, Duncan's Seedling; Summer Hill Seedling; Birmingham Blue (Dean).—Haulm, moderately robust, spreading, 18 inches long; stem, reddish; leaflets, broad, green; flowers, not opening; tuber, medium-sized, round; form, even; eyes, small, few, sunken at crown, which is depressed; skin, smooth, reddish-purple, deep purple in the eyes; flesh, white, firm. Moderate cropper. Greatly resembling Scotch Blue.

Surprise (J. White).—Haulm, very strong, 2 feet 9 inches long; stem, reddish; leaflets, small, rugose, deep green; flowers, purple, fertile; tuber, medium, round, flattened, depressed at crown; form, pretty even and regular; eyes, small, sunken; skin, smooth, deep reddish purple, deep violet round the eyes; flesh, white, firm. A good productive sort, and handsome. Late.

Skerry Blue (Sutton).—Haulm, very robust and vigorous, 4 feet long; stem, reddish; leaflets, small, rugose, green, with red veining; flowers, dark purple, very abundant, fertile; tuber, large, round, of coarse uneven appearance; eyes, large, deeply set; skin, rough, dark purple; flesh, close, yellow. A great cropper, and a hardy Potato, but very coarse. Late.

Series IV.—Skin Streaked or Flaked.

Barron's Perfection (Farquhar).—Haulm, moderately robust, erect, 2 feet long; stem, green; leaflets small, rugose, pale green; flowers, purple, very abundant, fertile; tuber, medium, long kidney-shaped, blunt at crown; eyes, small, few, mostly situate at crown; skin, smooth, occasionally rough, pale straw-coloured, generally flaked with brilliant crimson near the crown; flesh, white, close, of good quality. Very pretty. Moderate cropper. Second early. First-class certificate, 1874.

Cattell's Advancer.—Haulm, robust, almost erect, 3 feet long; stem, pale green, tinged purple; leaflets, broad, rugose, deep green; flowers, darkly purple, fertile; tuber, medium, half-long, flat; eyes, small, deeply set; skin, pale, straw-coloured, oblong, with a dash of purple near the crown; flesh, white, firm. A moderate cropper. Late.

Red Breadfruit.—Synonym, Old Scarlet Keeper (Taylor).—Fit for use late in spring.—"Royal Horticultural Society's Journal."

A SELECTION OF GOOD VEGETABLE SEEDS.

As gardeners and amateurs will soon be ordering their supplies of vegetable seeds for next year, perhaps a list of the kinds which I have found to be the most useful may be of interest to your readers. Seedsmen's catalogues now-a-days contain so many varieties, all described as first-rate, that it puzzles the uninitiated what to select. Of Cauliflowers, Veitch's Autumn Giant is a decided acquisition, and Walcheren, Early London, Lee's Imperial Dwarf, and Late Asiatic are all varieties that are sure to give satisfaction. Of Cabbages, Enfield Market, Wheeler's Imperial, Cocoa-nut, Cattell's Reliance, and the dwarf early kind, called Little Pixie, is good for planting close in the rows, as well as the rosette Colewort. Of Savoys, the dwarf green curl of the Globe, and its yellow variety, and Harrison's dwarf new kind, called King Koffee, I have found to be a good selection. Of Brussels Sprouts—the imported—Lee's Acme, a dwarf kind, and Scrymger's Giant are excellent sorts. Of Kales, Lee's dwarf, Curl'd Scotch, the Cottager's dwarf Abergeldie, and the Chou de Milan are all good and very hardy. Of early winter Broccolis, Snow's true Winter White, early Penzance, and Backhouse's Early are excellent; for early spring sorts, Dilcock's Bride, Frogmore Protecting, Watt's Excelsior, Cooling's Matchless; and, for the latest grown, the Leamington, Carter's Champion, and Cattell's Eclipse are all kinds which I can recommend. Of Lettuces of the Cabbage kinds, select All the Year Round, the Grand Admiral; and of the Cos section, Bath or brown Cos, Holmepark, King's Holme, and Paris white; for autumn sowing, choose Hick's Hardy White, the Hardy White Dutch, and the Hammersmith Hardy Green. Of Onions for autumn sowing, I find the best to be Giant Rocco, Globe Tripoli, and Danver's Yellow; and for the general summer crop, James' Keeping, Brown Globe, Deptford or Strasburg, and White Spanish or Bedfordshire Champion; these make as good a selection as can be grown. The Naples Early White, if sown very thick, comes in early for use in the summer, and for pickling. Of early

Turnips, the best is, the Strap-leaved, Early White, American Red Stone, and Veitch's New Red Globe. Of Carrots for forcing, use the French Shorthorns, and for the general crop early Shorthorn, James' Scarlet Intermediate, and long red Surrey, the Altrincham being the heaviest cropper, but it requires a deep soil. Of Kidney Beans the Negro Long-podded is a good early kind, and Canadian Wonder is a very long-podded sort, and excellent for the general crop; for forcing I find Fulmer's and Osborne's kinds the most productive. Of Peas innumerable varieties are introduced to notice, and growers can select from them either dwarf-growing or tall sorts, according to their means of procuring stakes for them. Of the dwarf sorts I prefer Little Gem, Multum in Parvo, and Blue Peter; and for early sorts of the taller section, William the First, Dickson's First and Best; and for the general crop, G. V. Wilson, Ne Plus Ultra, Veitch's Perfection, and British Queen. Of Beans I find the most productive croppers to be the early Long-pod, Green Windsor, and the Broad Windsor. Of Beets, Lee's Belvoir Castle, Dell's Crimson, and the New Chelsea. Leeks, the Ayton Castle Giant. Of Parsnips, the Hollow-crowned. Of Celery, the Leicester and Major Clarke's Red, and Sandringham and Incomparable White. WILLIAM TILLERY.

Welbeck.

POTATO-CROPPING EXTRAORDINARY.

LAST spring, Messrs. Bliss, of New York, offered premiums, "open to the world," and amounting in the aggregate to 1,500 dollars, for success with three new Potatoes, the object being as much to stimulate interest in improved methods of cultivation as to induce an extended trial of varieties, in the dissemination of which they were interested. The surprising achievements of those who competed for the 500 dollars in prizes of the previous year, together with the triple liberality of the new schedule, excited a wide-spread enthusiasm, and the cultivators who entered for the second contest were numbered by hundreds, and represented nearly every State in the Union, not to speak of some neighbouring provinces. The terms required that the crops should be raised in the customary way, no forcing processes being resorted to, or unusual method of multiplication; and competitors were given to understand that their statements must be duly witnessed and authenticated. These statements were promptly rendered, but, owing to illness of one of the committee, the awards have only just been announced. We present the main particulars in tabulated form, showing varieties tested, names and addresses of successful competitors, weight of crop, and amount of premiums. It is a series of apparently almost miraculous performances, but the trustworthy committee—Messrs. Geo. Thurber, F. M. Hexamer, and P. T. Quinn—assures us that, while abstaining from comment on the "astounding yields from single pounds," a "most careful and scrupulous investigation" has fully satisfied them of "the correctness of the statements." The following are the weights, &c., according to the "New York Tribune":—

FOR LARGEST QUANTITY EXTRA EARLY VERMONT FROM ONE POUND OF SEED.			
No. of prize.		lbs.	dollars.
1.—	Alfred K. Titus, Wilmington ...	708	100
2.—	J. I. Salter, St. Cloud, Minn. ...	698	50
3.—	Robert Lewis, Castleton, N. Y. ...	690	40
4.—	C. W. Walker, Washington, Kas. ...	674	30
5.—	A. W. Titus, Wilmington, Vt. ...	629½	20
6.—	Stephen R. DeWolf, Parrsborough, Nova Scotia ...	615½	10

FOR LARGEST QUANTITY COMPTON'S SURPRISE FROM ONE POUND OF SEED.			
No. of prize.		lbs.	dollars.
1.—	P. C. Wood, Esther, Ill. ...	900	100
2.—	Robert Lewis, Castleton, N. Y. ...	874	50
3.—	A. Loveless, White Mills, Penn. ...	832	40
4.—	J. I. Salter, St. Cloud, Minn. ...	811	30
5.—	C. W. Walker, Washington, Kas. ...	684	20
6.—	Chas. Whiting, Jasper, N. Y. ...	588½	10

FOR LARGEST QUANTITY BROWNELL'S BEAUTY FROM ONE POUND OF SEED.			
No. of prize.		lbs.	dollars.
1.—	H. C. Pearson, Pitcairn, N. Y. ...	1,018	100
2.—	A. Loveless, White Mills, Penn. ...	811	50
3.—	J. I. Salter, St. Cloud, Minn. ...	782	40
4.—	Robert Lewis, Castleton, N. Y. ...	749	30
5.—	Henry Bullis, Canton, N. Y. ...	720½	20
6.—	Charles Whiting, Jasper, N. Y. ...	696½	10

FOR LARGEST QUANTITY EXTRA EARLY VERMONT, GROWN ON ¼ ACRE.			
No. of prize.		lbs.	bush. per acre. dollars.
1.—	D. Steck, Hughesville, Penn. ...	6,247	416 28-60 100
2.—	Jeff. C. Hoch, Kutztown, Penn. ...	2,642	176 8-60 50
3.—	A. Hewlett, Kent, Ohio ...	2,584	172 16-60 40

FOR LARGEST QUANTITY COMPTON'S SURPRISE, GROWN ON ¼ ACRE.			
No. of prize.		lbs.	bush. per acre. dollars.
1.—	Mrs. M. A. Royce, Home, East Tenn. ...	7,350	490 100

FOR LARGEST QUANTITY BROWNELL'S BEAUTY, GROWN ON ¼ ACRE.			
No. of prize.		lbs.	bush. per acre. dollars.
1.—	A. Rose, Penn Yan, N. Y. ...	8,899	593 16-60 100
2.—	D. Steck, Hughesville, Penn. ...	8,055	537 50

The committee explain that for the second series of premiums there were so few entries that every competitor receives a prize, so that this can scarcely be considered a test of the yield per acre of the respective varieties. This is to be regretted, as it was expected, and very naturally, that the more valuable information would be

derived from the reports of the modes of culture by which large crops are produced on a given surface, than from those showing how one pound of seed is multiplied a thousand-fold. From data at hand the committee say they find that there were many larger yields from quarter acres by non-competitors than by some of those who received prizes. The unfavourable season and devastations of the Colorado beetle diminished to such a degree the crops of many who intended to compete, that they did not feel warranted in entering upon what they considered a hopeless venture. Of the merits of the Potatoes, as developed under this later and more extended test, it is said that there is general acknowledgment of the superiority of the Vermont as an early variety, both for market and table, in fact, "the earliest and best in cultivation;" that Compton's has given not less satisfaction as a Potato of the highest quality, and that Brownell's Beauty, the newest of the three, has made "a splendid record," not only giving "much the largest returns," both from the single pound and the quarter acre, but eliciting "unanimous praise from all cultivators."

KILNS FOR CHARCOAL.

The common method of making charcoal in pits—that is, in conical heaps covered with a layer of leaves and earth—is here abandoned, and kilns are substituted for the pits. These kilns are made of

Conical Charcoal Kiln.

brick, one course being sufficient if bands of iron or timber framework be added to strengthen the brickwork. The most prevalent style of kiln is the conical shaped, as shown in the accompanying cut. A usual size is 24 feet in diameter, with an equal height, holding about 40 cords of wood. This size has been found to be the most economical. The cost of one of these kilns, complete in every respect, with a lining of firebrick for 10 or 12 feet up from the bottom, was £240. The wood turns out more coal than when burned in pits, and 43 to 45 bushels of coal to the cord have often been made with first quality hard wood. The extra yield and less cost

Square Charcoal Kiln.

give a very good profit upon the cost of the kilns. The wall of the kiln is carried up nearly straight for 6 feet, when it is drawn in and made to form a blunt cone. Upon the top a plate of iron is fastened in the manner of a key-stone to an arch. Bands of 3-inch hoop-iron, an eighth of an inch thick, are placed around the kiln, and drawn together (a) with screw bolts and nuts to strengthen it. There are double sheet-iron doors at the bottom and near the top of the kiln, by which it is filled with wood or emptied of coal, and a few air-holes (b), which may be stopped up with loose bricks, are left in the bottom. When the kiln is filled it is necessary to plaster over the cracks of the doors or any that may exist in the brickwork with well-tempered clay to exclude

air. The second figure shows a kiln of another shape, made to burn over 3,000 bushels of coal and holding eighty cords of wood. It is a parallelogram in shape with an arched roof, and strengthened by a framework of timber 10 inches square. The walls of this kiln should be a brick-and-a-half thick to stand the pressure of the gas which sometimes accumulates within and occasionally bursts one of them with great force. A usual size is 40 by 16 feet and 16 feet high, outside measure. These larger pits need four weeks for a round—that is, to be filled, burned, and emptied; the smaller ones require three weeks, which is about the time needed to “coal” a pit. —“New York Tribune.”

GARDENING FOR THE WEEK.

The Flower Garden and Pleasure Grounds.

Now that the weather has become mild the pruning and thinning of shrubberies, &c., may be at once proceeded with. The beauty and graceful outline of many valuable trees and shrubs are often irretrievably destroyed owing to the reluctance felt to remove or to cut back other plants which may be unduly pressing upon them. In very many instances, when belts or clumps of trees and shrubs are planted with the view to obtaining a desired effect at the earliest possible period, more plants are put in than are really necessary, or more than can, in the course of a year or two, find sufficient space to develop themselves; and it also happens, not unfrequently, that the necessary attention is not given to the arrangement or distribution of the plants in the first instance; consequently, two, or even more, valuable specimens are sometimes found growing so close to each other, that all are suffering more or less from crowding, and the dislike of removing or destroying any of the plants so circumstanced tends, in the long run, to disfigure and ultimately to destroy all. All this, however, may easily be avoided by bestowing a little care and attention upon the matter when the plantation is in course of formation. All valuable sorts, such as the various kinds of Cupressus, Juniperus, Retinosporas, Thuja, Thujopsis, Yews, Aucubas, Alaternuses, Arbutuses, variegated Hollies, &c., should be planted, in the first place, at such distances from each other (say 15 or 20 feet at the least) as would afford sufficient space for each specimen to attain its natural form and dimensions; while, to produce a finished or an immediate effect, the intervening spaces should be filled in with the more common varieties of evergreen and deciduous shrubs, such as the common and Portugal Laurels, Green Hollies, Lilacs, Spiræas, &c., which should be gradually cut away from time to time, as found necessary, in order to give space to the more valuable specimens, as they continue to require the same. Examine clumps or belts of Rhododendrons and other American plants, and if any of the more delicate varieties are being overgrown by the more vigorous-growing sorts, let them be cut away to the necessary extent, or removed altogether. It is in many instances advisable to lift and rearrange plantations of this kind about once during every three years, unless the plants have already attained dimensions which will not admit of its being done. Where, however, the plants are of moderate size, they may be moved at almost any season, with little or no risk, as their roots seldom extend far, and this circumstance renders it easy to transplant them. The present weather is also very favourable for the prosecution of any alterations or improvements which may be contemplated in the grounds or gardens, which necessitate the removal of soil, and the laying of turf, &c. All such work should, when the weather is favourable, be pushed forward with all possible despatch; as such work, if delayed until the season is considerably advanced, greatly interferes with the general routine of necessary operations, and it is quite impossible to keep a place in first-rate order while extensive alterations are in progress. Sweet Peas to flower early, if not sown early in November, may be sown now; and wherever the amount of stock of any kinds of bedding plants is limited, such may now be placed in gentle heat, in order to induce the production of material to form cuttings at the earliest period possible. Where Tricolor and other delicate variegated Pelargoniums were lifted from beds in the open air, and potted with a portion, or all, of their shoots remaining upon them, these shoots may now be taken off, and formed into cuttings, inserted singly into 3-inch pots; or larger pots may be used, and several cuttings may be inserted in each, to be potted off singly when rooted. The soil used should be a mixture of light loam and leaf mould, about two of the former to one of the latter, and a pinch of silver-sand should be dropped into each hole, before the cutting is inserted. The pots containing the cuttings should be placed on shelves, or on a bed of cinder ashes, in a temperature of about 65°. Bottom-heat is not necessary; and, if the soil used is moderately moist, no water should be given during the first week or ten days. Cuttings of the Tricolor Pelargoniums are generally found to root

somewhat slowly; consequently, it is necessary to insert them thus early, in order to have the plants of a useful size when the time arrives for planting them out. The beginning of March, however, is not too late to insert cuttings of all the green-leaved sorts. Dry roots of choice Dahlias may also be potted now, with a view to the production of cuttings; and seed of the Golden Feather Pyrethrum may be sown in pans or pots, and placed in a greenhouse temperature. —P. GRIEVE, *Culford, Bury St. Edmunds.*

Winter-flowering Carnations.

What are called tree or perpetual Carnations are now in full bloom in many places, and are most useful for button-hole bouquets or for specimen-glasses. Carnations of this class are easily cultivated, and the great quantities of red and white flowers which they produce are truly astonishing. The varieties which I find do best with me are Garibaldi, Life Guardsman, Valliant, Hubert, Vulcan, Clarabelle, Bewitching, La Belle, Miss Jolliffe, White Rival, Avalanche, Prince of Orange, and Golden Eagle, all thoroughly good winter-flowering kinds. Cuttings or pipings of these and others should be struck early next month. In order to have good flowering plants in autumn and winter, I select the best and strongest wood for cuttings, which I insert in a large 60-sized pot, placing from five to six cuttings round the edge. I plant them moderately firm, and then place them in a bottom-heat of about 75° or 80°. In a month or five weeks' time they will be found to be thoroughly rooted, and fit to pot off in small 60-sized pots. In making the cutting or piping, after determining the length required, the two lower leaves should be thoroughly peeled off the wood, leaving nothing but clear soft wood below the joint; then, with a sharp knife, cut close up to the joint. The best soil in which to strike such cuttings is loam and leaf mould, or loam and cocoa-nut fibre, with plenty of sand. I have often even struck them in cocoa-nut fibre alone. As soon as they are well rooted, pot them off in small 60-sized pots, selecting for the purpose some good loam free from wire-worm, and well mixed with plenty of sand. Place them in a frame on a slight bottom-heat until well rooted, keeping them close to the glass, in order that they may not get too much “drawn.” When thoroughly rooted, give them another shift into small 48-sized pots, and, while in these, “stop” them, so as to make them bushy and cause them to form more spikes. May is the best month in which to give them a general stopping. About the end of June I give them their final shift into large 32-sized pots, and, if they are unusually strong, a size larger may be used; but nothing is gained by using too large pots, for they must be thoroughly rooted—indeed, pot-bound—to flower well. The soil for the final shift should consist of good fresh turfy loam and sharp sand, and the pots should be well drained. When shifted into 48-sized pots, I set them in a cold pit; and, when finally shifted into their flowering-pots, they are placed out of doors on a north border. Staking as required, and occasional waterings with soot-water, are all that is needed until the end of October, when they should be carefully brought into pits or houses, in which they will flower all winter. The Clove, one of the most useful of all Carnations, will succeed perfectly if treated as has just been described. It should be struck early in spring, and grown on, when fine flowers may be obtained by Christmas or New Year's Day. Old plants, if planted out, will furnish a good supply of flower throughout the summer. It is not advisable to depend on the same plants flowering well two years running.—H. G.

Orchids.

From amongst these the warmest nooks in our conservatories are being supplied with their most showy flowers. Oncidiums, Odontoglossums, and Coelogynes, are in great beauty, and these, together with Phalænopsids, furnish masses of white flowers, orange and crimson and allied colours being furnished by Masdevallias, Adas, Sophronitis, Epidendrums, Barkerias, &c., whilst Cattleyas, Vandas, Saccolabiums, Lælias, Dendrobiums, Phajus, Restrepias, &c., afford an immense variety of both colour and form. Prepare materials for a general potting next month and the succeeding one. Begin to pot, as soon as practicable, Odontoglossums, Miltonias, Masdevallias, &c., and those not requiring this at present should be top-dressed. Any bulbous Calanthes—those of the vestita section—not yet placed at rest, should be laid on their sides and kept dry. As soon as any appearance of growth presents itself in the earliest-rested plants, re-pot them, and place them under growing conditions. Give the terrestrial Calanthes plenty of water when they require it, and if they are in vigorous condition a little weak manure-water will be very beneficial to them. Dendrobium nobile being now, as a rule, well set with flower-buds, may be forwarded by introducing some plants of them into a brisk temperature, and others may be retarded by keeping in rather a cool house or pit. Attend to the destruction of all kinds of insects, as their numbers can be more easily and conveniently reduced than later on in the season. Scale, green fly,

thrips, ants, mealy bug, red spider, woodlice, and wire-worms require attention. Keep Pleiones in a nice growing state; any of the varieties that have not finished blooming should be re-potted as soon as their last flowers are past. Maintain a moderately moist atmosphere in all the Orchid-houses, otherwise Phalaenopsids and other long aërial-rooted species will suffer.

Indoor Fruit Department.

Vine Eyes.—Those potted about a month ago should now be plunged in a bottom-heat of 80°; any corner that will hold them and furnish that temperature is suitable. They come away rapidly when plunged here and there in an early Queen Pine bed, but a heated frame serves the same purpose. Should any of them be dry, supply them with water not colder than the surrounding temperature. If deficient in number, eyes may still be made and be potted and plunged with the others. The root-pruning or turf-raising system, which originated at Dalkeith many years ago, may be practised by everybody. Six-inch squares of turf should be cut, the eye placed in the centre, and a number of them set in a wooden box; when, if the whole be put on the top of the hot-water pipes in a Vinery or any other structure, growth soon follows. These need no root-pruning, as the roots do not emerge from the square. When grown thus, care must be taken that the turf does not get too dry; if this should happen each turf should be lifted out separately and dipped in a pail of water. Another method is to fill a common propagating box with soil to the depth of 4 inches, place the eyes 6 inches apart in this, and treat them as in the former case until they have attained a height of 18 inches, when a large knife should be run through between each row, going down to the bottom at every cut; six days afterwards they should be cut similarly in an opposite direction. This forms them into squares by cutting all the long leading roots, which soon produce a host of rootlets from each stop. They should be lifted apart or be taken out and potted or planted before the roots again run into one another's squares. Where large quantities are grown the bed of a propagating-pit or Pine-stove may be used instead of boxes. In preparing the eyes for this system they should be planted from both ends. It is necessary to make a small hole in the soil and lay the eye flat, leaving the bud above ground. This turf-growing or root-pruning need only be practised on those intended for planting, as it is simply done with a view to preventing the roots from running into long unfurnished leaders or coiling into entangled masses around pots. For fruiting in pots it is immaterial whether the roots are coiled or not, provided there be plenty of them, without which no Vine will fruit satisfactorily.

Pines.—Avoid letting any water come in contact with or rest about this fruit while in bloom; inattention to this results in deformity. Holes and distorted development, which are sometimes seen in Pine fruit, arise from this kind of mismanagement, and nothing renders fruit more unsightly. In looking over suckers which were put in early in autumn those with their pots full of roots should be shifted into others a size larger, or they may start into fruit prematurely. When re-potted do not plunge them in a bottom-heat over 75°, as it is not yet time to encourage much growth in them. If too late, Early Queen fruit may be hurried on in a higher temperature after they have done blooming. Smooths and other kinds supplying fruits until the Queens are ready should receive careful watering and be otherwise closely watched. A little air admitted during sunshine, and a slight damp overhead when shutting up, greatly helps the fruit to swell freely.—J. MUIR.

Kitchen Garden.

Peas, started in gentle heat under glass, should not be allowed to draw up weakly; on the contrary, when about half an inch high, they should be removed to a cold frame to be hardened off. In sowing Peas on a south border, if the border is narrow, either draw the drills parallel with the wall or fence, or else, which is better, run them obliquely across the border so that the rows may range from south-east to north-west, in which aspect they will get the full benefit of the sun. Even early Peas should have plenty of room, at least 4 feet from row to row, and two rows of Brown Cos Lettuce should be put in between each two rows of Peas. Autumn-sown Peas, that are now up, should have a ridge of earth drawn up on each side of them, and they should have sticks placed to them, which alone will form a great protection; but, in addition, Spruce, Fir, or Yew branches may be placed on the windward side of them whenever cold weather is anticipated. Scatter soot freely over and about them; this not only keeps sparrows and slugs at a distance, but also strengthens their growth. Draw the lights off Cauliflowers in frames every fine day, and give air freely to those under hand-lights during mild weather, dressing them at the same time freely with soot or wood ashes. Cauliflower plants in pots on shelves in heat near the glass should be moved to cold frames to harden off. If

there is space indoors, a few of the strongest might be shifted into larger pots for early use. Lettuces planted in slightly heated frames or pits last November will now be turning in, and should be tied up to blanch in succession. Sow a few Lettuces, either on a hotbed or in a few boxes placed in gentle heat; at the same time, also, some Lettuce seeds may be sown in a warm position at the foot of a south wall. Give air freely to forced Asparagus, when fairly through the soil, to colour and flavour it; if the weather is sunny and drying, give a light watering, occasionally, of weak liquid manure, in which about 2 ounces of salt to the gallon has been dissolved; continue to mat up at nights, as, although the days may be mild, the nights are uncertain. Where young Onions are required for flavouring salads sow the Queen, or the common Silver-skinned, in boxes in heat. Sow also, at the same time, the same kind on a warm border for succession; or a few roots of Chives may be lifted from the border, planted in boxes, and brought on gently in heat for the same purpose. Pot in succession Mint, Tarragon, Borage, Balm, &c., to meet any demand likely to arise. Sow a little Basil in heat for early use, and Sweet Marjoram if no supply was secured in boxes in autumn. Make up a hotbed for early Turnips in the following manner: dig out the soil, in a warm sheltered place, 1 foot deep, and 6 or 8 feet wide, extending as far in length as is considered necessary, and casting the soil about equally on each side; fill the space so excavated with hot dung, or dung and leaves, treading it well down, and laying the bed with a slope to the south; return about 6 or 8 inches in depth of the soil, and rake it down to a fine tilth; draw drills 6 inches apart, and sow the early Strap-leaved Stone Turnip thinly; fill in the drills with sifted material saved for such purposes when the rubbish-heap was charred. Where leaves and dung are plentiful, ungenial soils may in this way (with a little extra labour) be made as productive, and much earlier than even the most favoured localities; and, where this mode of supplying earth-warmth can be assisted by top-coverings of glass, or, where glass is not available, by oiled calico, or light handy frames made of stout laths thinly and neatly thatched with straw or reeds—the thatch to be neatly secured to the frame with thin tar-line—success may be rendered certain, as the ground will be kept from freezing, and germination and growth go steadily on. The covers should be taken off every fine day after the young plants come up, and be put on again at night. Of course early Carrots, Turnips, &c., should be left much thicker than will be desirable further on in the season. As they will be used in a young state, the largest being drawn first leaves room for the remainder to grow. A good many dishes can be obtained from a small bed if a small-topped sort is sown.—E. HOBDAV.

Early Spring in a Paris Market Garden.

The frames and cloches are treated in the same way as during last month; all the glass is now out of doors. Air is given to the frames on the leeward side, and to the cloches always on the south side. All the hotbeds for frames should be finished; any others made after this are for cloches or the open air. Clear out the spent manure from Melon trenches of the preceding year, and use it on beds. Dig over and manure where necessary; rake the borders over, and surface-dress them with spent manure.—*Sowings*: In hotbeds under cloches and in the open air, Carrots, pink and red Radishes; in the borders and intermediate beds, Carrots and Radishes; in cold beds, under frames and cloches, Sorrel, Parsley, Chervil, curled Chicory, wild Chicory, Cauliflowers, some early Cabbage, Milan Cabbage, red Cabbage, Brussels Sprouts, Egg-plants, Asparagus, Borage, bulbous Chervil, Celery for the table; in hotbeds, curled Chicory, white Celery, Beans, Cress, French Beans, Cabbage Lettuces, Roman Lettuces, Melons, Potatoes, Capsicum, Parslain, Tomatoes; in the open air, red Onions and green Peas.—*Plantings and transplantings*: Plant black-seeded Lettuces and green Roman Lettuces in hotbeds under cloches or frames; Georges and Gotte Lettuces in cold beds, under frames and cloches; grey and red-seeded Lettuces in the borders and intermediate beds; in hotbeds in the open air plant Flageolet French Beans, and transplant the Melons sown last month; plant out seedlings of last month, such as Cabbages and white Onions; plant Garlics, Shallots and Chives, *Treatment of Growing Plants*.—Continue to supply some manure to Asparagus and Mushrooms. Fill up the alleys, re-make the shelter-heaps, water the hotbeds if they are too dry, remove decayed leaves from Cabbage and Roman Lettuces, weed and give air to the frames during the day, and cover them at night. *Crops Gathered*.—The first crops from the hotbeds, consisting of Cabbage Lettuces in abundance, black and red Radishes, Spinach, green Roman Lettuces, and Asparagus. Blanched and green Cardoons, Carrots, white and turnip-rooted Celery, Chervil, Mushrooms, wild Chicory, Milan Cabbage, Scallions, green Pumpkins, Cress, Spinach, Tarragon, Corn Salad, Turnips, Sorrel, Parsnips, Parsley, Dandelion, Leeks, Pink, red and black Radishes, Rampion, Salsafy, and Scorzonera,

are, as in January, the principal crops which are gathered this month. *Special Remarks.*—The open-air hotbeds may be replaced by hotbeds with cloches, and *vice versa*; the frames on cold beds by a bed of Rampion, the Celery by Cabbages, the Spinach by Onions, the sloping bed by a bed prepared for the early Melons, the white and turnip-rooted Celery by Flageolet French Beans, the Chives by Chervil, the Cabbages by white Celery, the Scallions by Melons and Tomatoes planted out, the white Celery by Scallions, the white Onions by a sowing of Spinach and small Salad. In the borders early Cabbages may be planted, and white Onions sown between them.

NOVELTIES FOR 1875.

Rheum nobile, Hooker.—Of this remarkable species of Rhubarb, till now unknown in our gardens, I am gratified in being in possession of fresh seed for the first time. This is a native of Sikkim, where it was originally found by Dr. Hooker, in whose valuable Himalayan journals it is thus described:—"The individual plants of *Rheum nobile* are upwards of a yard high, and form conical towers of the most delicate straw-coloured shining semi-transparent concave imbricating bracts, the upper of which have pink edges; the large bright glossy shining green radical leaves, with red petioles and nerves, forming a broad base to the whole. On turning up the bracts the beautiful membranous fragile pink stipules are seen like red tissue paper, and within these again the short branched panicles of insignificant green flowers. The root is very long, often many feet, and winds among the rocks; it is as thick as the arm, and bright yellow inside. After flowering the stem lengthens, the bracts separate one from another, become coarse red-brown, withered and torn; finally, as the fruit ripens they fall away, leaving a ragged-looking stem covered with panicles of deep brown pendulous fruits. In the winter these naked black-stems, projecting from the beetling cliffs, or towering above the snow, are in dismal keeping with the surrounding desolation of the season.

Brodiaea volubilis, Baker (*Stropholirion californicum*, Torrey).—This species is remarkable for its twining habit, the flower-scape often reaching the height of 7 or 8 feet, or even more. The flowers are produced in terminal umbels of from fifteen to thirty each, the perianth being of a light rosy-purple colour, nearly 1 inch long, of a tubular ventricose form, contracted below the mouth. The foliage is linear, somewhat fleshy in character, and from 12 to 18 inches in length. It is perfectly hardy, and of the easiest cultivation in any soil, but will probably succeed best in sandy loam. Seedlings will bloom the third year of their growth.

Centaurea americana var. **Hallii**.—This showy variety differs from the typical species, the *Plectrocephalus americanus* of Don, in nothing but its deep rich purple colour, which renders it much more ornamental than the ordinary pale lilac form. It does not appear to have originated from cultivation, but is a wild form received from Texas, having been collected by Mr. E. Hall, whose name it appropriately bears. It succeeds best in rich deep soil and warm situations.

Chlorogalum pomeridianum, Kunth.—This is an interesting plant of the easiest management. It forms large tunicated bulbs, invested with a mass of black hair-like fibres, which are said to be used for stuffing mattresses, and the bulbs themselves are so alkaline and mucilaginous that the plant is popularly known as the Soap Plant, and is not unfrequently used for detergent purposes. The leaves are broadly linear, somewhat channelled and recurved, with wavy margins; amidst them arises a rather slender scape, 2 to 3 feet high, with several spreading branches, along which the numerous white flowers are arranged in loose racemes. They are about 1 inch across, with spreading segments, and open only in the afternoon, as the specific name implies; but one blossom expands at a time on each branch. In dry soils it is apparently quite hardy. Seeds vegetate very readily, and the bulbs grow freely when sufficient space is afforded them, but several years usually elapse before they attain a flowering size. It is a native of California.

Eriogonum compositum, Douglas.—This is a vigorous-growing species, with large ovate-cordate, stalked foliage, chiefly radical, dark green above, densely tomentose on the under surface, and naked scapes about 1 to 1½ feet in height, bearing a large, much divided umbel of whitish flowers, having at a little distance something of the aspect of the inflorescence of a *Spiræa*. Being perfectly hardy, and easy of cultivation, it will prove a desirable addition to the perennial flower border. The seed-like fruits are larger than in *E. umbellatum*. It is a native of Oregon and Northern California.

E. racemosum, Nuttall.—Although less robust than the preceding, this species is fully equal to it in interest—if it does not exceed it, owing to the delicate rosy tinge of its flowers. It produces from a woody root a tuft of ovate-oblong stalked leaves, which are about 2 inches in length and woolly beneath. From their

midst arises a naked forked scape, from 1½ to 2 feet high, with erect branches, bearing numerous white flowers tinged with rose, about as large as *E. umbellatum*. It is a native of New Mexico and Utah.

Galactites tomentosa, Moench.—Among plants remarkable for their ornamental foliage, the *Galactites tomentosa* deserves honourable mention. It is a Composite indigenous to the shores of the Mediterranean, growing from 2 to 3 feet high, of erect branching habit, with spiny divided foliage, prettily blotched with white, in the manner of *Silybum Marianum*, nearly smooth above, but very cottony and white on the under surface. The stems and branches are terminated by solitary flower heads of a lilac-purple colour. If sown as early as February, the plant blooms the first season, but stronger specimens are obtained by sowing in autumn. It succeeds best in good loamy soil.

Lobelia subnuda, Benth.—Some plants, like individuals, attain notoriety from the earliest moment of their introduction; whilst others of equal merit are unaccountably ignored, and reach celebrity only after the lapse of years. To the latter class belongs this little plant, for although cultivated in Germany, and offered in seed catalogues under the *alias* of *L. picta* during the last five or six years, it does not appear to be at all known in England. Its chief merit consists in the character of its foliage, which forms neat spreading tufts 4 inches in diameter or more, each leaf being about an inch in length, of an ovate form, doubly serrated at the margin, of a deep purple on its under side, and of brownish-purple colour above, the mid-rib and veins being green, thus affording a pretty contrast of tint, approaching that seen in some species of *Anætochilus*. There is a little variation in different specimens, some exhibiting a more decided opposition of colour than others, but in all it is more or less marked. The flowers are comparatively small, of a very pale blue colour, and are freely produced on erect branching stems about 6 inches high. They add but little to the attractions of the plant, and may be removed when seeds are not required. It appears most at home in the greenhouse, but will probably succeed fairly in the open border, during the warmer months of the year, where the purple tints of the foliage will be deepened, and its size somewhat diminished. If tried out, it should be planted in half shaded places. A native of Mexico.

Mentzelia ornata, Torrey and Gray.—This may be popularly described as a robust *Bartonia*-like plant, 2 to 4 feet high, with sinuate-pinnatifid foliage, rough, like the whole plant, with short barbed hairs, each branch bearing several white flowers 4 to 5 inches in diameter, with ten spreading acute petals, and a large central tuft of stamens from 200 to 300 in number. It is probably a biennial plant, and expands its splendid sweet-scented flowers towards the close of the day. Though long since figured in the "Botanical Magazine" from dried specimens, under the name of *Bartonia decapetala*, it has not, I believe, been in actual cultivation. The seeds are of an oval flattened form, bordered by a narrow wing, and are about one-sixth of an inch in length. If sown early, seedlings might possibly flower the first season.

M. nuda, Torrey and Gray.—Like the preceding, this species has a tall stem, rough from minute barbed pubescence, with lanceolate, or oblong-lanceolate, sessile toothed foliage, and large ten-petalled flowers, which differ from those of *M. ornata* in their yellowish colour and rather smaller diameter, being usually about 3 inches in diameter. If sown early it will bloom the first season, but it will probably bloom in greater perfection when treated as a biennial, as the flower would then be produced in the long summer days, instead of the cooler and shorter ones of autumn.

M. multiflora, Nuttall.—This species is readily distinguished from both the preceding by its dwarfer habit and golden-yellow colour of the flowers, which features, notwithstanding their smaller size, may make it quite as acceptable in European gardens. In its scabrous whitish stems, lanceolate pinnatifid foliage, and winged seeds, it does not widely differ from *M. nuda*. Whether vespertine or diurnal is uncertain, but plants would probably flower the first year.

Pentstemon Palmeri, Gray.—This handsome species is of robust habit, attaining, in good soil, a height of from 3 to 5 feet. The lower leaves are petioled, varying in form from ovate-lanceolate to spatulate, coarsely and sharply toothed; those of the stem broadly ovate, entire, and semi-amplexicaul, or sometimes even connate, all being of a fleshy texture, and, like the whole plant, smooth and glaucous. The flowers are borne in a many-flowered naked panicle, from 18 inches to 2 feet long; the corolla, which is peach-coloured, being remarkable for its short inflated tube and gaping mouth, as well as for the long reflexed lobes of the lower lip, each marked by a central reddish line, and the conspicuous projecting yellow-bearded sterile filament. It is quite hardy, and will succeed in almost any well-drained soil.

P. cyananthus Brandegei, Hooker.—The *Pentstemon cyananthus*, of which our present plant is but a form, is itself

regarded by Dr. Gray as but a broad-leaved variety of *P. glaber*; it is, therefore, somewhat difficult to seize upon characters sufficiently prominent in a botanical sense to warrant the separation of a new form. Many plants, however, which can scarcely be distinguished botanically from allied forms, are yet, in a horticultural point of view, sufficiently distinct, and deserving of a specific designation; and this is likely to be the case with the *P. cyananthus* var. *Brandegei*. On the authority of Professor Porter, it is said to differ from the allied forms in being minutely puberulent, in having a more robust habit of growth, in its broader foliage, and larger thyrsoïd spike of flowers, which are of a beautiful bright azure-blue. It is probably as hardy as *P. glaber*, and will succeed with the same treatment, seedlings flowering the second season.

W. THOMPSON.

Ipswich.

OBITUARY.

WE have this week to record with much regret the death of Mr. William Port Ayres, an event which took place at his residence, Forest Hill, on Thursday, the 14th inst. Mr. Ayres, as is well known, was an able writer on all matters connected with gardening. In discussions on horticultural subjects of all kinds he generally took part, and, owing to his long experience as a skilful practical gardener, the decisions at which he arrived were, as a rule, correct. He was elected a corresponding member of the Royal Horticultural Society, and was for some time editor of the farming and gardening portion of the "Nottingham Daily Guardian." While at Nottingham he took out patents for certain improvements in hot-house building, a business to which his whole time and energies were of late devoted, and one in which, just when success had been reached, he was struck down by disease, which in a few months reduced his manly frame to a mere shadow, and to which he ultimately succumbed. He belonged to a race of good gardeners, his father having been a skilful cultivator, and, in days gone by, a prominent exhibitor at the great shows then held at Chiswick. He was born at Shipley, in Derbyshire, and died at the comparatively early age of fifty-nine.

Mr. A. Turnbull, of the firm of Dickson & Turnbull, nurserymen, Perth, died at Bellwood, Perth, on the 19th inst. He was born in 1789, and, after having completed his education, joined his uncle in the nursery and seed business at Perth, which has now been carried on for upwards of half-a-century. By his death the local institutions of Perth will lose a warm and generous friend, for he was ever ready to assist them when necessary. Notwithstanding his great age, he continued to maintain his health and vigour till the closing days of his life. On New Year's Day he felt so strong that he made a good many calls; but, as in the case of many other old people, the severe cold was too much for him, and he was attacked with bronchitis, from which he never rallied. Mr. Turnbull has a wide circle of relatives and friends in Perthshire and neighbouring counties, by whom his loss will be deeply felt.

We have also to record the death of Mr. Buckley, who was for many years manager for Messrs. Rollisson, of Tooting. His acquaintance with plants and plant culture was extensive, and fully recognised by the large numbers of professional friends with whom his position brought him in contact. He died on the 18th instant, after a long illness.

PERSONAL.

WE are pleased to state that the health of Mr. Henry Ormson, the well-known horticultural builder, which has been for some time past in a precarious state, is now completely re-established.—Mr. Stevens, late foreman to Mr. Penny, at Sandringham, has been selected to take charge of Major Barton's fine establishment at Straffan House, Kildare.—Mr. Lee, late of Oteley Park and formerly of Blenheim, has been appointed successor to Mr. Brown, deceased, at Powis Castle, Welshpool; and Mr. Pritchard, late foreman at Shipley Hall, Derby, succeeds Mr. Lee at Oteley, Shrewsbury.—Mr. Dell, for many years gardener to Sir John Pakington, now Lord Hampton, is to succeed Mr. Smith at Lord Dartmouth's, Patshull, Wolverhampton.—Mr. Henderson, late of Sir Hy. Peek's, Wimbledon House, has taken the management of the gardens of John Deacon, Esq., Mabledon Park, Tunbridge; and Mr. Ollerhead, late of Killermont, Glasgow, has succeeded Mr. Henderson at Wimbledon.—Mr. Morley, formerly with E. J. Coleman, Esq., Stoke Park, Slough, has succeeded Mr. McFarlane at C. Lucas's, Esq., Warnham Court, Horsham.—Mr. T. Williams, for twenty years superintendent of the indoor gardens at the Crystal Palace, having relinquished the appointment, is open to an engagement for similar duties in a large public or private garden.—It has been arranged that the competition for the Carter Cup and other prizes, offered by Messrs. James Carter & Co., will take place on the 7th of July in the Royal Horticultural Society's Gardens, South Kensington.—With the view of encouraging other amateur growers of succulents to show their plants this season, Mr. Peacock has determined not to compete at any of the exhibitions this year.—On the occasion of the opening of the Museum of Science and Art at Edinburgh the other day the great hall was extensively decorated by the Lawson Nursery and Seed Company, on the ground floor of which they had fitted up a most beautiful and tasteful conservatory.

NOTES AND QUESTIONS.

[THE following notes and questions came to hand, or were answered too late for insertion in their several departments.]

Tacsonia sanguinea.—Allow me to thank "J. M." for his correction in respect to this *Tacsonia*. I inadvertently placed it in the first division of climbers for a cool house, instead of in the third or stove section, where it ought to have been.—T. BAINES.

Masdevallia attenuata.—This is not a showy Orchid, inasmuch as plant, flowers, and all might easily be put into an ordinary match box. It has bright green spatulate foliage and solitary snow-white flowers, with buff-coloured tails characteristic of this genus. It is now flowering freely in the Orchid-house at Kew.

Culverwell's Prolific Marrow Pea.—I can recommend this as a Pea for everyday use, particularly to those who have a large supply to furnish from a limited space. It is just the Pea to take the place of the Champion of England. Mr. Culverwell uses it not only as a late Pea, but as a Pea for everyday use. It is, in fact, a giant Veitch's Perfection.—THOS. KEETLEY, *The Gardens, Newton House.*

Raising Yuccas from Seed.—What is the best and surest way of germinating *Yucca* seed, the most suitable soil, and is bottom-heat required?—HOY. [The seeds of *Yucca* should be sown in a peaty soil, in pots half filled with broken bricks or potsherds, and placed in a temperature varying from 55° to 60°. They do not require bottom-heat.]

Orobanche on Primula.—On the 5th inst. I removed an *Orobanche* minor from the root of a plant of *Primula sinensis fimbriata alba*; the parasite was in bud, having been forced with the *Primula*. The seed, no doubt, came from some road-scrappings, the plant often occurring on Clover by the road-side. The seeds, however generally remain in the ground until they meet with a suitable nidus—that is, a leguminous plant, *Galium mollugo*, *Rubus fruticosus*, *Centaurea*, *Achillea*, *Cannabis*, or Ivy. It has not, I believe, before been recorded on a *Primula*.—G. S. BOULGER.

The Best Nectarines.—In his list of Nectarines (see p. 524), Mr. Fish seems to have over-looked Lord Napier and Duc de Telliers, both excellent Nectarines, which I have found to be the best bearers in cultivation. Lord Napier bears well, even in a young state, and its fruit is of the very largest size. Except Lord Napier, Pitmaston Orange (a really good Nectarine), Violette Hâtive, and that excellent variety, Duc de Telliers, all others produced with me this season but a fruit or two each; even the Elruge failed. Lord Napier and Telliers are much superior to Hardwicke Seedling and Balgowan.—JOHN TAYLOR, *Hardwicke Grange.*

Conifers for Swampy Ground.—I would recommend your correspondent "Salmoniceps" (see p. 42) to plant the following in his swampy ground, viz:—*Juniperus vulgaris* (communis), and its varieties, *J. hibernica* and *Suecica*, *J. Sabiniana*, *Tamariscifolia*, *J. tripartita*, *virginiana*, and its varieties, *Camæcyparis sphaeroidea* and its varieties, *Taxodium distichum*, *Thuja occidentalis*. Besides these, the following do very well in rather wet but well-drained ground, viz.:—*Abies canadensis*, *Cupressus Goveniana* and *Lawsoniana*, *Picea grandis*, *Pinus austriaca*, *maritima* (*Halepensis*), and *tuberculata*, *Retinospora ericoides*, *leptoclada*, and *squarrosa*, *Sequoia sempervirens*, and *Widdringtonia cupressoides*.—WILLIAM BARRON, *Elvaston Nurseries, Borrowash.*

Hepaticas under Glass.—The best plant I know of for winter blooming in a cold greenhouse is the common blue Hepatica. Last spring I potted a large plant of it, which I took into my greenhouse about ten days ago and it is now one mass of lovely blue flowers. There are two great advantages in forcing the Hepatica: the buds, though apparently dormant, will open almost while you wait, so that you may have your plant in full bloom at an exact date; secondly, under glass you may obtain any amount of seed, and, as the pollen ripens, cross the varieties well together. I mean to try *Hepatica angulosa*, the loveliest of the section, next year. Hepatica seed should be sown in a sheltered spot in fine soil; it takes a long time to come up, but plants thus obtained bloom better than any others. I have seen a large bed of two-year old plants that were quite superb.—F. MILES.

Raising Seedling Geraniums.—I sow hybrid Geranium seed directly it is ripe, leaving the feather end sticking out. Some seeds come up at once, and some are coming up now—two months, at least, after being sown. Two years ago I tried to raise a good white-flowered white-edged Geranium, and saved a seedling with a white edge that had been raised from Madame Vaucher. This edge disappeared in the spring, and the whole plant merged into a fine bronze, somewhat like Egyptian Queen. Towards the end of the summer the leaves became quite green, and now it is nothing more than an ordinary salmon-eyed Zonal. The lovely Zonal Geranium, Rose Peach, was raised by Mr. Pearson from Violet Hill. Seedlings from Rose Peach are frequently variegated; and I have also got a finely variegated sport from that Geranium. Now, Violet Hill, the parent, I have never seen variegated; and though it is one of the very best bedding Geraniums in point of colour and flower, it was raised by Messrs. Henderson for a Tricolor. So this variegation has passed through, but never appeared in, Violet Hill, and now comes out in Rose Peach.—M.

The Blue Vanda.—I am much pleased with the figure which you have given of our blue Vanda (see p. 43), which has been in Mr. Lane's possession twenty years. It came from the Botanic Gardens, Glasgow, and was a very small plant in a small 60-sized pot. In 1867, when it first came under my care, it had a long bare stem. Six years ago it pushed some fresh roots from amongst the lowest leaves; the following spring I cut it off just below the fresh roots, put it in a much smaller basket, and plunged it in a hotbed. It soon began to grow, and in a short time it was removed to the stove, where it stands on a front stage of slate, with hot-water pipes underneath. The top of the plant is about 18 inches from the glass. The compost in which it is planted consists of lumps of good rough peat and equal parts of crocks and charcoal. About March I begin to water it overhead, and continue to do so till the flower-spikes show themselves, and then I cut off the supply. When the flowers begin to fade, I gradually withhold water, which is then given about, say, once a week. I never let the soil become quite dry. When this Vanda is growing it likes abundance of water and plenty of air. I ought to mention that for three months my stove temperature falls as low as 50° at night, and sometimes lower than that; in fact, it is rather an intermediate-house than a stove. Mr. Lane tells me that this Vanda never flowered so well as it has done these last five years.—W. SMITH, *Badgemore, Henley-on-Thames.*

Ragley Hall.—In our account of the places laid out by Mr. Marnock, this was printed Hagley, instead of Ragley. They are, however, two totally different places. At the former (Lord Hertford's) Mr. Marnock carried out work; at the latter (Lord Lyttelton's) he never did.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

A PLEA FOR FRUITS AND VEGETABLES.

WHEN the Canon Sedillo was ill he sent for Dr. Sangrado, who was considered, in Valladolid, as a second Hippocrates. His faithful biographer describes him as a man of solemn appearance, deliberate in his discourse, and mathematical in his reasoning. He was a tall thin person, and had kept the shears of destiny employed during forty years at least. "Pray, what is your ordinary diet?" was his first question. "My usual food," replied the Canon, "is broth and juicy meat." "Broth and juicy meat!" cried the physician, "then I do not wonder at finding you in this condition; such dishes are poisons in disguise, and snares which luxury spreads for mankind in order to ruin them the more effectually. You must renounce all dainty victuals; the most wholesome are those which are the most insipid, for as the blood is so, it requires such aliment as partakes of its own nature. And do you drink wine?" "Yes," said the Canon, "diluted with water." "Oh, that makes no difference," replied Sangrado. "What irregularity is here! Under such a regimen as this, it is a wonder you are not dead long ago. How old are you, pray?" "I am in my sixty-ninth year," replied Sedillo. "Aye," said the physician, "an early old age is always the consequence of intemperance. If you had drunk nothing but water all your life, and had been satisfied with simple food, such as boiled Apples, for example, or Peas and Beans, you would not now be tormented with gout, but would still enjoy the perfect use of your limbs." Without going to such lengths as the sage, it is to be regretted that fruits and vegetables do not form a more important part of our daily meals. It is quite certain that, from early times, we English have been great consumers of animal food. From the days of our warlike ancestors, whose huge barons of beef, and oxen and sheep roasted whole, are described with national pride by their chroniclers, down to a very recent day, when, at our civic and social feasts, it was thought right that the table should "groan" under a load of heavy dishes, we have looked with a pity bordering on contempt upon the delicate dishes which a French Phillis provides for her household. We grow splendid fruit and excellent vegetables—the best in the world—and yet they occupy a very subordinate place at our tables. How seldom, among the substantial viands which compose our breakfast, do we find any of the thousand-and-one excellent dishes which can be made of Tomatoes, Vegetable Marrows, Artichokes, &c.! It is the same at luncheon and dinner; vegetables are too often represented by sodden Greens or ill-cooked Potatoes; while fruit, which ought to form an important part of every meal, is merely used as a dessert. Who can properly appreciate the delicate flavour of a Strawberry or Greengage after a heavy repast composed of three or four courses? I should like luncheons which consist, for example, of a light vegetable soup, followed by a compôte of Raspberries, Gooseberries, Apples, or any fruit in season, with cream and bread, to be the rule instead of the exception. As it is, in the houses of the middle classes the greatest monotony prevails. Where there might be a number of wholesome and inexpensive dainties, their meals are generally heavy and unvaried. As regards the working people of this civilised country, their cooking is, as a rule, as bad as it can possibly be. With the exception of those who have been cooks in affluent families, their wives are unacquainted with the first rudiments of the art. Where they might have, at a small cost, capital vegetable soups, good fruit puddings, and jams, with Potatoes cooked in many different ways, they are too often satisfied with the latter succulent, sodden and watery, as an accompaniment to the black and juiceless chop, or the red herring, which is such a standing dish with the poor of our towns. Of the composition of good soups or broths they know literally nothing, though they gratefully accept soup as a gift from some considerate and more intelligent neighbour. In Scotland, plain

cooking is far better understood, and I have many times dined sumptuously at humble tables on hodge-podge and barley broth—a couple of excellent dishes. When we turn to France, who cannot remember the good repasts (not to speak of Paris, and the Trois Frères, or the Maison Dorée) at wayside inns, where "Carottes à la Maître d'Hôtel," or "Haricots Verts" formed the staple, and the meat occupied but a secondary place? Then, an excellent dessert, not always composed of the "Quatres Mendiants" (Almonds, Raisins, Nuts, and Figs), crowned the whole. In Germany, vegetables are not so well cooked (though they are grown in great abundance), and the fruits there are of inferior quality; still excellent dishes are composed of both. The compôtes of Apples, Pears, and Cherries, and some of the vegetable preparations are not excelled by anything in England. No Englishman, it is true, could be found to tolerate Sauer-Kraut; but this may be merely prejudice. In Denmark (though rather behind in culinary matters) a favourite and delicious dish is Rød-grød. It is simply fruit of any or various kinds, stewed until quite tender, and passed through a sieve, then mixed with boiled Semolina, or Rice-flour, and sugar, and eaten with cream and bread. In Italy, the poorer classes live almost entirely on vegetables, fruits, and Maccaroni. Chestnuts form the staple food of the labourers in some parts. Tolerable bread is made of them, and they may be cooked in many different ways. In Tuscany, a soup made of bread and Beans is a sort of national dish. The labourers cannot afford to eat much animal food. They boil their meat first for soup, and serve it up afterwards in a kind of stew with Potatoes, Carrots, and Turnips. This is called "Lesso." Indian Corn is extensively used; they make of it Polenta (a kind of mash), which is both good and wholesome. Thus, the Italian peasant, though poorer than our English labourer, has a pleasant variety in his meals, to which his northern brother is a stranger. No doubt the short winters and sunny climates of Italy render animal food less necessary. I was nearly forgetting Spain, but there the art of cookery is nearly as backward as everything else. Nature has been bountiful indeed to this ill-starred country, but her gifts are not turned to the best advantage. When the traveller from this island of fog and mist finds himself in a Spanish market, he is dazzled and delighted with everything which meets his eye. The costumes of buyers and sellers—the graceful mantilla shading the olive cheek of beauty—the brilliant colours of the peasants' dresses, richly ornamented in some parts of Spain with gold and silver coins, the enormous red umbrellas, the clatter of fans, mingling with the ceaseless splash of the fountains in the middle of the market-place, the piles of fruit and vegetables, green and golden Melons, purple Grapes, Pomegranates and Peaches, the huge bouquets of Roses and Lilies, mixed with other flowers which grow luxuriantly in that sunny climate—all these form a picture, which, when once seen, can never be forgotten. But the people themselves make but a poor use of their advantages. Though Spain is the country where the Olive flourishes best the oil is very inferior, and it frequently gives an unpleasant taste to the dishes, in the preparation of which it is lavishly used. Cabbages and Beans are the principal vegetables, if we except Lettuces and salad herbs. The splendid fruits I have described are seldom cooked in a manner to tempt a fastidious palate, but one hardly misses this because they are in such perfection that a good meal may be made of them in the raw state, with the addition of bread and chocolate. I must not forget burnt Almonds, without which no Spanish dessert is complete. To return to England: I often wish that every cottage had a garden, where fruit and vegetables could be grown, where the good housewife, like Chaucer's Grisilde, could gather the

Wortes and other herbs times oft,
The which she shrede and sethe for her living.

The principal object of village horticultural societies should be to spread the knowledge of gardening, and to encourage amateurs and small cultivators to grow the best kinds of fruit and vegetables. It appears to me that a great reform is wanted here, but I have travelled a long way from my starting point, and must reserve what I have to say on this head for a future paper.

NOTES OF THE WEEK.

— THE rare and chaste *Cattleya Bogotensis* is now in flower in Mr. Michael's collection, at Highgate. The flowers measure fully 6 inches in diameter; sepals and petals crisped, and of the purest translucent white, the petals being 3 inches long by 2 inches broad; the lip is also white, and beautifully stained in the interior with lemon-yellow.

— LAST week's Potato imports into London amounted to 1,160 tons and 3,691 sacks from Dunkirk, 12,617 bags from Antwerp, 576 sacks from Ghent, 169 tons from St. Brieux, 992 sacks from Boulogne, 171 tons from Calais.

— SOME idea of the loftiness attained by trees of the genus *Eucalyptus* may be formed when it is stated that some of the specimens of the *E. amygdalina*, measured by Baron von Müller, the Government Botanist of Victoria, would overtop the cross on St. Paul's Cathedral.

— THREE new species of *Eranthemum*, recently received at Kew, are remarkable for the beauty and brilliant colouring of their foliage. None of them have yet flowered, and they only bear the provisional names given them by Messrs. Veitch, who obtained them from the South Pacific Islands.

— THE annual meeting of the Royal Horticultural Society is fixed to take place on February the 9th.

— WE are glad to hear that Mr. T. Bruges Flower, F.L.S., of Bath, has just finished the concluding number of his "Flora of Wiltshire," containing the Grasses and Ferns, which has been published by the Wiltshire Archaeological and Natural History Society, in their magazine. It is hoped that it will be found practicable to republish the whole of this excellent Flora in a single volume.

— THE "Revue des deux Mondes" of 31st January contains an interesting paper by M. Planchon, on *Eucalyptus globulus*. The subject is treated from the botanical, economical, and medical points of view. The *Eucalyptus* is known to combine an iron texture with rapidity of growth. Some estimates have lately been made with reference to its value as a forest tree in Algeria. According to M. Cordier, if 1,000 of the trees were planted closely together, there might be cut down in 5 years, 500 of them worth 600 frs.; in 10 years 250, worth 1,323 frs.; in 15 years 125, worth 1,473 frs.; in 20 years 60, worth 1,521 frs.; and in 26 years 60, worth 3,195 frs.

— THE plants figured in the "Illustration Horticole" for the three months ending 1874 are—*Sciadocalyx Luciani*, a pretty Gesnerad raised between the Foxglove-flowered *Sciadocalyx* and *Tydaea pardina*; *Theophrasta imperialis*, a well-known species; *Camellia Miss Minnie Merritt*, a variety in the way of Jubilee; *Fourcroya Lindeni*, a pretty kind with yellow-bordered leaves; *Dracæna Troubetzkoi*, a species from the Melanesian Islands, intermediate between *D. Regina* and *albicans*; *Clavija Rodekiana*, a *Theophrasta*-like plant, and a valuable addition to the genus to which it belongs; *Spathiphyllum heliconiæfolium*, a beautiful Aroid from the banks of the Rio-Huallaga, in Peru; *Dracæna densicoma*, a green-leaved kind, which produces great pendent spikes of creamy inflorescence; and *Kentia Balmoreana*, a handsome Palm discovered on Lord Howe's Islands by Mr. Moore, of Sydney.

— WE have received, from Professor Sargent, a report respecting the present condition of the Arnold Arboretum, presented to the President and Fellows of Harvard University, which shows that, in spite of limited means, satisfactory progress has been made in the two years during which Mr. Sargent has been entrusted with its formation. The soil and indigenous growth on the various portions of the grounds have been carefully studied with a view to a proper determination of the permanent disposition of the various collections, and several thousand trees and shrubs have been raised for the future plantations. An inspection of the trees already growing in the Arboretum showed that many of them were in a miserable condition from long neglect of proper thinning, and the consequent want of food, light, and air. To remedy this as far as possible the woods and old plantations have been gradually thinned out, the weak, deformed, and unhealthy plants being cut first, and then such as interfered with fine single specimens, or with specimens of only occasional occurrence. Returning health in many of the trees, and a greatly improved appearance of the woods and belts of timber, are already apparent, although the operation of thinning out old woodlands, with a view to forming healthy, well developed trees is necessarily a slow one, and must be extended over many years. Already many noble specimens of some of the finest native trees are scattered through the open portions of the grounds, giving to the arboretum a furnished appearance, and proving that the situation is particularly adapted to the use to which it is to be devoted. A catalogue of the trees growing in the arboretum is subjoined to the report.

CHERRY CULTURE ON WALLS.

It is often desirable to grow the Cherry on walls, not only with the object of having early fruit, but also of prolonging the supply, and this may be done by taking the first crop from a south or west wall, and the latest off a north wall. Considering the prolific habit of the Cherry under proper treatment, it is well worthy of a wall, for few fruits are more refreshing or agreeable when perfectly ripe—as a Cherry should be before it is eaten. It is only those, however, who grow their own fruit that can have it in this condition, for the Cherries of the shop are generally gathered too early, the growers being eager to push their stock into the market as soon as possible. The Cherry comes early into bearing if it is well trained and the knife is used sparingly in pruning; but damage is often done in this way to the trees, especially where no skilled gardener is employed, or where the jobbing hand is called in to do the pruning, and often where the proprietor himself, under the impression that pruning of some kind must be performed, sets about the task without a very clear notion of what is required. Perhaps I cannot better give an idea of how to proceed with young trees against a wall than by describing my own practice here, and its results. Ten years ago I had to deal with a west wall of young trees, which had been planted about three years. I found they had been pruned hard back annually, and, being in a strong soil, they had simply pushed out gross wood every year, without showing the faintest signs of fruit. As I found these in an unpruned condition, I proceeded to have all the most awkwardly-placed shoots cut clean out, and as many of those remaining as could be accommodated without crowding laid in their entire length, so that I at once secured fine little fan-shaped trees several feet in diameter. I also root-pruned them slightly at the time, but I have not had occasion to repeat the operation since, the laying in of the young wood entire, or nearly so, and summer pinching, rendering it unnecessary. The following season the young shoots flowered freely and bore their first crops. During the summer the breast wood was pinched regularly, a work of little time, the leading shoots were laid in as they grew, and additional young limbs led off from the upper sides of the old ones, as the spaces between these widened with the extended radius. In this way the vigour of the tree was expended uniformly in the production of bearing wood. In winter no pruning was necessary, except the shortening of the spurs here and there where the foreright shoots had been pinched. All the time, of course, the previous year's wood—that which bore the fruit—was forming natural spurs and buds for future crops; for it must be borne in mind, that the Cherry bears freely upon both the previous year's wood and the old wood, the latter furnishing bearing spurs, which yearly increase in size and bear, in fact, the most fruit. By the third year the trees had extended themselves so much that it was found necessary to remove every alternate one, and since then they have again met and filled the space allotted to them, or nearly so. The only circumstance to be regretted is, that eventually they will not have as much room as they would require. There is nothing more inimical to the welfare of a stone-fruit tree than a restricted development of the branches. There cannot be the least doubt that a free extension is the surest guarantee of fertility. It is astonishing what an area a Peach, Plum, or Cherry tree will cover in a few years, without the least danger of the trees getting scant of bearing wood at the bottom; yet an excuse is often offered for the mutilating process, but one that is invalidated by the facts of the case, for no trees break and furnish so freely as those mentioned, no matter how long the shoots may be. If allowed, an ordinarily vigorous Peach tree, for instance, will, by its powers of extension, cover 600 square feet in eight or ten years, and ought to bear a proportionate quantity of fruit. The Cherry trees in question continue to bear every year profusely, on every branch, from its furthest extremity down to the bole, within a foot of the ground. We never disturb the roots. The border is planted with Gooseberries, and these are manured occasionally. Sometimes only a mulching is applied, which is particularly beneficial to the Cherries in dry weather. The Cherry will keep well on the tree after it is quite ripe if a mat be hung over the tree. In this way we have kept early Cherries till nearly the end of August, thus prolonging the supply from June. J. S. W.

THE FRUIT GARDEN.

GRAFTED GOURDS.

At the last exhibition of the Central Society of Horticulture in France, the public had an opportunity of inspecting the magnificent collection of Cucurbitaceous plants shown by M. Gaillard, and were much struck by specimens of fruit of different forms and colours,

Yellow Gourd, into which the stem of a Green Pear-shaped Gourd has been introduced, the latter having a portion cut off and replaced by a part of a White Gourd.

which, though united, belonged to different kinds. This was the result of grafting; and, although such unions naturally appear extraordinary to people unacquainted with the art of grafting, yet those who are familiar with vegetable physiology are aware that, under certain conditions, a portion cut off one fruit and placed on another will unite firmly and grow. One condition is indispensable, viz., the fruit must be of an analogous character, and belong to the same family. Another precaution that must be taken is to raise the

Spanish Gourd, on which an Elector's Cap Gourd has been grafted.

epidermis, or the skin of the fruit to be united, so as to bring the cellular tissue, in course of formation, into contact; for, unless this is done, no lasting union can take place. The first of the accompanying illustrations represents a yellow Gourd, into which has been introduced the stalk of a green Pear-shaped Gourd, from which a large slice has been cut off and replaced by a corresponding

section of a white Gourd. In this case a perfect union has been effected. The second illustration represents an Elector's Cap grafted upon a green Spanish Gourd. In this case it was sufficient to partly peel the Gourd and make an incision into the tissue so as to form, as it were, a socket for the Cap, which was also peeled so as to expose a portion of the cellular tissue. The third illustration represents a Virginian Gourd, the extremity of which has been cut off and a portion of the interior scooped out in order to obtain the seed. This having been accomplished, the two parts were again drawn together with a thread, but in such a manner that they did not fit exactly. In spite of this, however, a union was thoroughly effected. The facility (says the "Revue Horticole," from which this account is translated), with which Cucurbitaceous plants will unite under the circumstances just described is most likely due to a gummy resinous principle, which is found in the tissues of the stalks and the fruit of these plants, and which assists adhesion in the first place, and then the more perfect junction of the two surfaces.

RAISING VINES FROM EYES IN TURF.

MR. MUIR (see p. 80) states that raising Vine eyes in turf originated at Dalkeith many years ago, and goes on to describe the system of raising the eyes on 6-inch square pieces of turf, exactly as recommended by me at different times and practised since 1867, and now practised in many places. I would much rather have avoided raising the discussion now, but, trifling as the matter is, I think such an unauthorised statement should not pass unchallenged. In the first place, then, I would say that, personally, Mr. Muir must be unacquainted with what took place at Dalkeith at the time he states, for he never was there, and he is clearly not read up in the

Virginian Gourd, of which the end has been cut off, and, after the seed was extracted, replaced.

matter. Secondly, during the eight years I was at Dalkeith I saw every Vinery on the place planted but one, which was renovated, and not a single eye was raised on turf for any purpose, but in small pots as Mr. Thomson describes in his book on the Vine, though Mr. Thomson planted one-year-old Vines on turves and in baskets, and also Vines from eyes after they had been raised in pots and were about 18 inches high. Thirdly, I began the turf system with the first Vinery I planted after I came to Wortley, at the end of 1864, and Mr. Thomson began his turf practice in 1870, with the Vines for planting at Clovenfords; and, during the incidental discussion that was raised then on the subject by others than myself. Mr. Thomson stated that his practice and mine had no points "in common," except that we both used turf—he a bed of turf 4 inches deep, and I 6-inch square sods, which I moved about according to circumstances, just the plan Mr. Muir now adopts, and recommends to your readers in the calendar for this week. I hope, therefore, your correspondent will see fit to retract statements, which, to say the least, he has made without taking the trouble to discover whether they were correct or not. It is not a question of spreading the roots of pot-raised Vines on turves or trays, but raising the eyes on turves from the beginning, in order that no check may be experienced, as is apt to be the case when they are raised in pots, and afterwards transferred to the turves. The use of scoops or baskets for young Vines that have to be moved, is not new, for French Vine growers have adopted this plan from time immemorial in transferring layered plants from the parent

plant to the border. The flat turf trays are a decided improvement in this respect, but the principle is the same—the object in both cases being to avoid disturbing the roots in planting. J. SIMPSON.
Wortley.

THE GRAPE VINE.

Preparing Permanent Vines for Early Forcing.

FOR very early forcing it is much better and more economical to employ pot Vines, as these can be pushed harder than is desirable with permanent Vines under similar circumstances, and a greater crop can be got from a given area. Still, in some places, where there are many Vineries, one house can often be afforded for early work; and it is here necessary to point out the conditions to be observed in such a case. Vines that are forced early for a number of years get weaker and weaker every season, as might be expected, seeing that growth is produced at the most unfavourable period of the year, and under very artificial and adverse circumstances. It is most desirable, therefore, that Vines intended for such work should be thoroughly established and in good health and vigour to begin with. This point is too often lost sight of, however, in the desire to hurry the Vines into early action. The “working round” process is begun almost before the Vines are more than half grown, and the consequence is, that by the time they are fit to start in November for a first early crop, they are already enfeebled and quite unfit for more than a few years duty, and have to be either rooted out and replaced, or let back for a few years to recruit themselves. Under these circumstances, therefore, it is not advisable to force other than aged Vines that are in good health and that have not previously been started before the natural season. One month or six weeks is as great a leap as should be attempted in one year; and, assuming that the Vines have been previously started about the 1st of March, the middle of January or beginning of February, will be soon enough the first year. The second year they may be started about the middle of December, and the third they will be fit to start in November, about as early as it is ever found desirable to start Black Hamburgs for an early crop, and not often needful in these days when late Grapes can be kept till the beginning of summer. The directions already given for culture during the growing period, and pruning, &c., are also applicable to early forced Vines, only that more discretion in the matter of airing and temperature, and care generally, is required. The ability of the Vines to stand hard forcing for a number of years in succession depends greatly upon intelligent practice in these matters. The object should be to dispense with artificial heat as much as possible, and husband the sun heat on all favourable occasions. Air should be admitted constantly by the hot air ventilators, and by the back and front shutters whenever possible, if only through a chink; but avoid draughts; and damping must be reduced to a minimum while neutralising the scorching effects of hot pipes by keeping the border in a properly moist state. As regards bottom-heat, watering, &c., the reader is referred to my remarks on that head.

Inarching.

Inarching and budding are resorted to when it is desired to increase the varieties in a Vinery without planting (or employ particular stocks) which is inconvenient, and often attended with poor success in a border that has been made for some years. These two practices, especially the first, have quite superseded grafting with Vines, being both simple and almost certain to be attended with success. I prefer inarching in all cases; but budding is also a sure way of getting a strong cane, and even fruit, the first year, as the buds attached bear just like the natural buds of the Vines—according to Mr. Stevens, of Trentham, who has practised budding frequently with great success. Inarching is best performed upon the young growing wood, while it is still green, but when the tissues are just beginning to harden. It is performed by simply bringing the stock and scion together, and taking a slice of each, with a sharp knife, about 2 inches in length and of equal breadth, where the junction is to be effected, and bringing the two together so that the edges of both meet exactly, when they are secured above and below the union with a tie of matting, and afterwards bound tightly together with soft matting the entire

length of the cut. No further wrapping is necessary. The stock may be stopped four or five joints above the union, but the point of the scion must be encouraged to grow. A complete union will generally be effected in about a fortnight, or less if the Vines are growing vigorously, but it will be necessary to examine the shoot frequently during that time to see if the matting is not cutting into the bark as the growth progresses. When the union is complete, the bandage should be removed entirely, and the stock cut clean off just above the junction, so as to direct the current of sap into the scion alone. Young Vines so inarched upon old stocks, as a rule, make vigorous canes the same season.

Budding.

This operation is performed in two or three ways; but Mr. Stevens' plan seems to be the simplest and most successful, judging from the canes I have seen. Budding is performed on the ripe wood about the end of August or beginning of September. A slice of bark, equal in size to the bud to be attached, is cut off the Vine to be budded, at the desired place; the bud is then sliced off, with a small portion of the wood and bark adhering, and placed on the seat prepared for it on the stock, slipping the lower end of the bud into a small slit in the bark, to keep it in its place. It should then be bandaged securely with matting, and protected with fine Moss to keep it moist until it has taken. Budding may be very advantageously performed on old bare Vines that have not broken regularly, so as to furnish them with spurs in a regular manner.

J. S.

(To be continued.)

POTTING PINES.

THE potting of Pines should always be done with care, although it is far from being the most important operation connected with their cultivation. In many instances there is a great deal of unnecessary labour expended in such work. For example, it is a very common method to ram the soil about the plants with a piece of wood as firmly as it can be beaten, and I have never been able to see the advantage of this; for, after contrasting plants thus treated with others that were potted, by pressing the soil about the roots with the hand, like any ordinary plant, I have come to the conclusion that the practice should be dispensed with, although it dates back to the introduction of artificial Pine growing. With what object it was originally adopted, I cannot say; but I am convinced that those who still persist in the practice, do so because the attempt has never been made to do without the “pin” while potting. Some of the finest stocks of Pines in the country have been grown without it. The only pressure to which the soil used was ever subjected, was to give the pot a good shake after the plant and soil were placed in it, to settle the latter about the roots, and finish off by giving the whole a couple of firm knocks on the potting bench. The soil was not heavy and clayey, or less firming would have been needed, but somewhat light and well filled with fibre, as all Pine soil should be. I do not mean that the plants should be placed in the pots so loosely that they may be swayed to and fro with the hand; but the soil can be filled in with sufficient firmness without ramming. I have sometimes heard it contended that firm potting saved frequent watering with many kinds of plants; but I do not consider it beneficial to any kind of plant (except aquatics) to have the soil so stiff and retentive about the roots as to render watering unnecessary, when the plant in its natural state would require it. Plants are not alike in their requirements of water. These, in some, are regulated by the rapidity of their growth; in others, by the texture of the leaves and the temperature in which they are grown; but it is always a good healthy sign when a plant, of whatever kind, takes water freely. The most judicious mode of potting Pines is to have the soil and pots ready before disturbing the plants. The pots, if not new, must be clean and dry inside. Large bits of crock should be laid at the bottom, with smaller pieces on the top to the depth of 2 inches, and a layer of Moss over all, to prevent the soil from passing through and obstructing the drainage. The soil should consist of pure fibrous loam, to every barrow load of which should be added an 8-inch potful of finely-ground bones. This, well mixed, is superior, for Pines, to any other manure. The soil should be heated to 60°, and should not be so dry as to crumble into dust when worked between the fingers, or so wet as to stick to them. When preparations have reached this stage the plants may be brought forward. Sometimes the leaves are not tied up when potting, for fear of putting any of them out of their growing form; but there is always less risk of damage when they are gathered carefully together and tied neatly up with a piece

of strong matting, before taking them from the bed in which they have been growing. Small suckers, less than 1 foot high, should be placed in threes in a 6-inch pot, in a triangular position. The suckers should be pushed into the soil, which should be pressed well in with the finger and thumb, so as to leave an inch between the surface and the rim of the pot for water when needed. The bottom of the sucker should be placed midway between the surface and the drainage, so as to admit of rooting both upwards and downwards. The soil for these should not be rougher than will pass through an inch sieve. When the large plants are turned out of their pots, the old crocks must first be cleared away. The quantity of soil to be removed will depend on the state of the soil and roots. It is always safe to rub off all soil in which there are no roots; and, if the soil be the least sour or sodden amongst them, it must be taken out also, as the outside roots will not remain healthy if they have first to pass through bad soil. The smallest of the leaves round the neck should be carefully abstracted for an inch or two up the stem; when this is done, many small roots appear ready to start into the soil when placed in contact with it. It is not safe to clear the leaves further up the stem than where the pale brown colour ceases, which is found on all hardened stems. When placed in the pot the soil should cover the bare stem, or the benefit which they otherwise gain through the operation is lost. If the old ball is large and entire, the finest of the soil should be worked down the side of it.

J. MUIR.

GRAFTING TO TEST NEW VARIETIES.

EVERY fruit-grower should experiment constantly in the way of grafting, and thus prove for himself the value of different varieties of fruits. In his visits among his neighbours, whenever a good fruit is brought to his notice, he should at once procure a few scions, and wrap them up in moistened paper until he reaches home, when they should be consigned to a box in his cellar; this box should contain damp Moss or saw-dust, and should be placed in a cool, moist corner, away from a furnace. In consigning the scions to this receptacle, great care must be taken that they are carefully covered all round with the Moss or saw-dust, to keep them from coming in contact with the air. Some kinds of fruits, such as Apples and Pears, graft much more readily than others. Stone fruits, such as Cherries, Peaches, and Plums, can be reproduced more satisfactorily by means of budding. The uninitiated in these matters should, therefore, turn their attention more particularly to the first, and after they have gained proficiency it will be time enough to try their hand at the latter. In testing new varieties, it is much more sensible to own a single limb on an old-established tree, than to purchase a young plant, and wait for several years to ascertain perhaps, after all one's trouble, that it is not at all suited to the locality. The largest limbs may be marked quite easily, by merely making a downward cut through the bark, for, say, an inch in length, having previously cut off the branch squarely and smoothly. The graft should not be cut wedge-shaped as in the customary cleft-graft system, but the cut must be all on one side, and inserted between the bark and wood of the limb, beneath the slit aforesaid. After tying it into place firmly, apply a good coating of grafting-wax or clay, and the operation is complete. Several grafts may thus be inserted round a large-sized limb, and these after "taking" will soon grow over and completely cover the end, so as to make a neat appearance afterwards. Occasionally, when we have a large number of varieties on one tree, the stronger kinds will smother the weaker, if care be not taken to keep the former within bounds; and yet there are instances where as many as twenty and even thirty distinct varieties of Apples are growing on one tree, all in bearing condition, and the owners sweep away the premiums for the best and largest displays at every show where they exhibit. Old Pear trees, whose usefulness has passed away, may be made to produce bountiful crops of delicious fruit once more, by grafting over their tops with good kinds; indeed, there are plenty of such instances existing, to prove how very valuable grafting is, where good healthy stocks already exist.—JOSIAH HOOPES in "Tribune."

MILDEW ON VINES.

A DAMP stagnant atmosphere favours the development of mildew, which often attacks Vines in all stages of growth. Sometimes it appears on the first leaves that expand from the eye before the wood attached to it is well rooted. On Vines planted out, it appears on the wood, on the foliage, and on the berries. It generally seizes on the leaves first, and looks like a small speck of mould, similar to that which appears on decayed fruit. These specks very soon multiply in number and increase in size, until the entire leaf is speckled. Before the disease has reached this stage, the berries are

generally affected as well, and in much the same way. It may be rubbed off them with the hand, but not before the damage is done. The part soon shows signs of a small brown spot, and decays. When mildew extends to the wood, it remains on it until it is matured, and when ripened brown the spots of a dark colour are still visible upon the affected parts. Abundance of fresh dry warm air will stay the progress of, but not eradicate the disease. Liberal dustings with flowers of sulphur are the most effectual remedy, and, if applied in time, will save all. Machines are manufactured for distributing sulphur, and they do their work efficiently. Those who have not got them, may use a flower pot with a piece of thin gauze cloth tied over the mouth. On young Vines every leaf should be dusted all over every third day until the mildew has altogether disappeared. Other Vines must be treated in a similar way. Bunches affected should have the sulphur well shaken through them. As soon as there is a certainty of its being overcome, the sulphur should all be syringed from the leaves and fruit with clean water. Traces of it generally remain, however, and any Vines affected during the time of their growth should be well washed, and afterwards painted with sulphur, when the pruning and cleaning is done. If care, in this respect, be not taken, it may appear again next season, when the Vines are started into growth, and the consequences may then be more serious. If young Vines are propagated from wood which has been affected with mildew, it appears on them immediately they begin to grow; so that a good deal of caution is necessary wherever its presence is suspected.

J. M.

Small Apples the Best.—As Apples remarkable for size receive at the best public exhibitions the largest share of attention, it may not be amiss to say a word in favour of the varieties which produce fruit small in size, but of exquisite flavour. Let us take, for example, that well-known little Apple, Sam Young, which at this season of the year is a "real gem." Then, again, there is the Margil, Pitmaston Pine, and Powell's Russet, all of which are small, of the highest quality, and keep well. Indeed, I question whether there is another four to match, for late use, these three and Sam Young. Just before the fruit show held at South Kensington in November last, I made up my mind to show a collection of little Apples, and had samples of a large number of varieties selected. They were a lot of "little beauties," but, on looking them over, the thought struck me, "what use is there in sending these gems, the merit of which have small chance of being recognised by the judges?" Therefore, after turning the matter over in my mind, I determined not to send them, and subsequent events proved that I was right, for in the competitive classes the largest fruit was invariably placed first, and in some of the classes provided for specified varieties large and coarse examples were put before others well finished, although only a size or so smaller. I am not, mind you, complaining of the judging on that occasion, but simply mentioning a fact to show that it is no of use to exhibit these small kinds, although they are invaluable for the dessert.—JOHN SCOTT, in "Gardeners' Magazine."

Vicar of Winkfield Pear.—This Pear had high commendation from several cultivators, at the great Boston pomological meeting, as a good and very profitable sort, when properly managed. It usually over-bears; but when two-thirds of the fruit is picked off early in the season, and it is left on the tree till the frost comes, it is greatly increased in size, colour and quality, and becomes a good eating Pear. A member from Connecticut stated that he had thus grown them weighing 16 oz. Haskell, of Massachusetts, said the best Pears he ever ate in February were of this sort, large, with a blush. Coit, of Connecticut, had fine cooking Pears in March, when thinned to one-quarter. Earle, of Illinois, said it had grown in favour with him since he had thinned it; but in most localities in the West it had failed from the blight.—"Cultivator."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Soil for Vine Borders: ALPHA. No exact proportion of materials for making Vine borders can safely be given, as so much depends upon the quality of the materials to be used. The more clayey the loam, the more brick rubbish, or the like, is required to give porosity; and the richer the loam, the less bones or other fertilising agent is required. If, to three parts of your sandy loam, you add one part of lime rubbish, and to every cubic yard half a bushel crushed bones you will probably secure a good result.

Budding with Gooseberries and Currants.—In the "Revue Horticole," M. Carrière describes a way of budding Gooseberries practised by MM. Croux, of Sceaux. Among other experiments of this nature, MM. Croux have trained a number of plants of Ribes palmata to a single stem, and budded the stock with Gooseberries and Currants of various colours and forms. The result, as may be imagined, has been both curious and ornamental. So complete was the natural conformity between the stock and the graft that it was hardly possible to tell the spot where the latter had been placed.

VENTILATION OF HOTHOUSES.

It was with considerable astonishment that I read, in the pages of a contemporary, the other day, the following piece of advice to a correspondent:—"Ventilating hothouses: No; there is no better or other way of opening the sashes than by sliding them down!" This advice was accompanied by suggestions as to how the sliding process might be facilitated by means of three "small castors" on each side of the sash. Had such advice been offered fifty years ago, it perhaps would not have surprised any one; but that there should be any horticulturist still alive who is so benighted as to really suppose that there was "no better or other way" of ventilating than that under notice, is what I could not have believed, had I not evidence before my eyes. It is further suggested, that the sliding up and down of the sashes might be done by "simple machinery." I imagine that it would take a donkey-engine, and about as much gearing as would fit up a coal-shaft, to accomplish the feat in any ordinary range of houses. I never saw ventilation on the sliding-sash principle attempted to be worked by machinery, for the simple reason, I apprehend, that, getting quit of the old cumbrous narrow sash, with its accompanying deep and broad rafters, is a chief object with modern hothouse builders. No greater improvement has taken place in hothouse structures during the last thirty years, than the adoption of the rod and lever, and the continuous shutter, back and front, for ventilating purposes; and none but gardeners who have managed both old and modern houses can realise the immense saving in labour effected in this way. Besides, the system has just set the garden architect at liberty in the matter of design; for he was formerly compelled to adhere to one plan, in order to accommodate the sash with its ropes and pulleys. Now we can have a roof nearly all glass, and plenty of light, whereas, formerly, we had between the sashes about 9 inches of solid woodwork, which cast a shade over the whole interior of the house as soon as the sun passed the meridian. Many, and elaborate, have been the schemes promulgated from time to time to secure the "perfect aëration" of our hothouses. It is not so long since gardeners were amused regularly with the picture of a Vinery—called, I think, the "gardener's house," a fearfully and wonderfully made structure—in which innumerable air currents were represented by a shower of arrows that continually and irresistibly reminded me of the "November meteors;" but it seems to have gone the way of all other such fanciful notions. As far as our fruit-houses are concerned, whether span-roofed or lean-to, I do not see that we want anything superior to the usual top and bottom shutters above referred to. With these, and a coil or two of pipes close to the side openings, as are usually seen now, the most thorough ventilation can be given at any time, and the best results have been accomplished by such means. What more, therefore, do we want? The most elaborate system of ventilation will never enable a novice to grow Grapes, or anything else, better than he did before. Airing is like firing. It matters little what kind of boiler is employed, if some degree of intelligence is not exercised in using the coal-shovel and the damper. Airing is a matter of judgment, and will always be so. The great object of those who have troubled themselves on the subject of ventilation, seems to be the establishment of a free circulation of air throughout the whole structure. This is an important point no doubt, and in very lofty and wide houses, in which plants are placed upon the floor, at points distant from the roof or sides of the house, some special means of carrying the air in amongst them by air drains communicating with the external air, and opening at the desired points inside, if possible, under or near the hot-water pipes, should, and may be provided, in the same simple manner as aëration is effected in some Vineries; but in ordinary-sized lean-to or span-roofed houses, I have never seen the necessity of such provisions for dislodging stagnant air, which cannot possibly accumulate anywhere to a serious extent in such structures, if ventilation at the sides and top of the house is attended to. Distribute the heating apparatus equally over the floor of the house, and you may be sure that the equilibrium will be sufficiently disturbed to prevent air stagnating in any particular part of it. In a Vinery 20 or 30 feet wide, with hot-water pipes at the back, middle, and sides, and shutters at the sides and top of the

house, the merest chink of air at each shutter will sweeten the atmosphere throughout in a few minutes. The air from the top ventilators dashes straight down to the floor, displacing or mingling with the warmer air in its descent, while the front air rushes along the floor until, heated in its progress, it ascends again and escapes at the apex of the roof, and in this way the air in every part is kept moving. In usual practice, there is frequently an unreasonable prejudice against opening the front ventilators. Many practitioners persist in opening the back or top shutters wide, day after day, in sunny weather during spring, and only the merest chink at the front or sides, and all this time with their eyes open to the fact, perhaps, that both in their Vineries and Peach-houses the fruit at the bottom of the rafters is about a month in advance of that at the top of the house—a disparity due entirely to the system of airing. It is surely right to admit air always at the warmest part of the house—in fact, I believe it is this theory, wrongly applied, that has led to the practice of opening the top shutters most. When, however, we see the fruit progressing faster at the bottom than the top of the house, and the foliage broad and thin, we may be quite sure it is there that air in most abundance is required, and adapt our practice accordingly. For years this has been my practice in pits and houses, and I believe I could generally show crops, which, for regularity in ripening over the whole area, is all that could be desired. Perhaps it will be argued that a successional supply of fruit is afforded when the fruit ripens off later at the top. The only reply I can give to this is that the practice is injurious, and it is not good to depend upon an accident for a succession of fruit. The object in all plant structures should be to keep an even temperature throughout; to avoid parching here and chills there; and this, I maintain, is more a matter of experience and attention than anything else. CHEF.

A Small Herb Garden.—There is poesy and savouriness in the very name. There may be likewise order and beauty in it. The most unsatisfactory things in gardens, especially small ones, are the herbs, scattered hither and thither all over the place, and time and patience are exhausted in hunting them up when required. Quite a useful feature might be made in every garden, however small, of the herbs, were they only brought together into one place and arranged in order. The best disposition for herbs is in beds. These may be from 2 to 4 feet wide, with foot alleys between them, and the length almost double, or, at the least, one-third more than the width. This arrangement in beds is the very essence of an herb garden. Of course in small gardens one entire bed will not be needed for any herb. In such cases several kinds may be easily grown together—such, for instance, as common and lemon Thyme, Pennyroyal, and Marjoram in one; Fennel, Sage, and Tarragon in another; and Basil, Summer Savoury, and Golden Purslane in another. Mint should always have a bed for itself, as Mint sauce is much in demand. Chervil, again, is much wanted in many families for salads, also Burnet, Hyssop, &c. These three are the semi-cordial herbs, Horehound for sore throats, Tansy for tea (not that anybody ever drinks it), Camomile for face-ache and stomach ailments, Rue for the gapes in poultry, Lad's Love, and any curious herbs that the villa gardener may have a fancy for. A bed should also be reserved for Angelica, used by those who know the luxury of its shoots candied in sugar, and for the growth of Borage, for flavouring claret cups in hot weather. Again, the herb garden is just the place for the orderly and systematic cultivation of all small salading such as Mustard and Cress, a constant succession of young Onions, a bed of Chives, the cultivation of Radishes throughout the season, and the growth of Rampion, Lettuces, Endive, &c. All this would find abundant furniture for a good many beds, and by changing these for the different products a nice succession of cropping might be maintained. Finally, several beds should be set aside for the high-class cultivation of Parsley—a plant sadly neglected in small gardens. Nothing is more useful in a household for flavouring or garnishing, and it is just as easy, on a right system, to have magnificent leaves, exquisitely curled and clean, because raised high above the ground by their strength and stature, as to have and use the small dirty leaves that have to do duty as Parsley in so many houses. Let the Parsley have a bed of rich deep soil—if a yard deep all the better; sow a good curled kind thinly; as soon as fairly up thin the plants to a foot apart, and let them grow away freely. That is the whole art of growing and using Parsley, and making it really one of the most beautiful plants in the garden. Sow in March, May, and July for succession. If the garden of herbs is too small for the devotion of

one or more beds to Parsley, sown at different seasons, then the whole herb garden might be fringed round with Parsley, and the garnishing and flavouring plants themselves be garnished with its beauty. No portion of any garden, large or small, not even excluding that wholly devoted to flowers, will afford more pleasure than an herb garden well furnished and kept. There will always be something growing and doing in it.—“Villa Gardener.”

THE FLOWER GARDEN.

HARDINESS OF BEGONIAS OF THE REX SECTION.

Few plants have been greater favourites than the different varieties of the Rex section of Begonias, which have, however, dropped prematurely out of cultivation, or into places of third-rate importance. Few plants are more striking than Begonia Rex, Marshallii, Duchesse de Brabant, Queen Victoria, Comte de Lemminghe, with their endless hybrids of every shade and degree of variegation. But their rapid increase and great variety seemed to produce a reaction that has ended in driving most of the varieties of this section quite out of the seed catalogues. This is to be regretted, as few plants are more useful, easier cultivated, or enjoy more immunity from insects than Begonias. As to propagation, any portion of a leaf with a prominent vein is convertible into an independent plant, and any number can be raised from seeds. In fact it

Begonia of the Rex section.

was partly this facility of increase that led to the present reaction against Begonias of this class. They were multiplied unduly in most collections, to the displacement of plants of more permanent value. They were also unfortunate, perhaps, in not finding at once their proper places, which were obviously baskets, brackets, and walls. Strikingly beautiful, as pot specimen Begonias are, most of them were more so when overhanging a basket, depending from a bracket, or clothing the bricks, or stones, and walls with beauty. In no position are they more useful or effective than as wall plants. The half-creeping stems and leaves look best when depending from, or displaying themselves close to a wall. Small semicircular pots of cement stone, or clinkers, may easily be made on or suspended from walls. These will suffice to grow variegated Begonias in for years. The object is not single specimens, but successfully well-formed, properly-shaped leaves, the smaller in size the better. The cramping of some of the varieties into small root spaces alters, and, for this purpose, improves their character. The stems become much shorter, the leaves smaller, and, of course, there is room for more in number. In corners, and in recesses, at the ends, or under stages, larger places may be found to take full-sized plants. It is astonishing how well these Begonias grow and colour in shady places. They are equally beautiful grown against a back wall as in full sunshine, the white of some of the varieties being even more silvery, and the green more verdant in shady places than in exposed ones. Even the reddish-leaved varieties have been found to keep their colour well in the shade; and some of those delicate hardy

strains in the way of Comte de Lemminghe, that seem as if their surfaces were sprinkled over with gold-dust, put on a higher beauty in the shade. I now come to the last and most important point of all. Most of these variegated Begonias have been reckoned and treated as stove-plants; doubtless, too, they will live and flourish in a high temperature; but so they also will in a low one. In the coolest greenhouses they may be grown well and in safety. For many years past, a back wall of a flower passage or verandah has been furnished with these variegated Begonias in home-made cement pots, after the pattern of the Fern bricks made by different firms. In winter the thermometer has frequently been down to 30° (within the last month it has been as low as 20°), and yet the Begonias show no sign of injury. Part of the passage has an opaque top, and front lights are furnished with plants, and, in fact, there is a large proportion of wall. The light is, consequently, much intercepted, yet these Begonias, in spite of the shade and the cold, continue to thrive, and do their part well in covering the bare wall. Some years ago we tried bedding out Begonia Rex, Marshallii, and others, and tried 500 plants in a ribbon border. They were not satisfactory, and the experiments were not repeated. They suffered, however, from an excess of heat, not cold. The sun burnt them brown. Since then I have frequently seen plants in sheltered positions in the open air looking pictures of health and beauty; but though they will never be popular as bedding nor even as sub-tropical plants, they ought not to be overlooked where plants suitable for the furnishing of conservatories and greenhouses and other shady and covered places, are in demand. During winter, and in a temperature under 40°, variegated Begonias should be kept rather dry and in a semi-dormant state. The object of low temperatures should be to conserve the old, not to develop new beauty. Doubtless young plants in full growth, taken from the plant-stove and placed in such temperatures as are here indicated, would be killed outright, thus adding another proof of the fact, which cannot be too often repeated, that hardiness is a matter of condition, more, even, than of constitution or species. No plant can be called altogether hardy when in full growth. Take the Oak in June and expose it to 10° of frost, and you will kill its young growth, though it had stood bravely out against zero only four months previously; and so in degree with all plants. If you want them to be hardy, secure a strong habit and well-ripened wood and leaves, and you make them so. Reverse these conditions, and the same amount of frost will kill them at once.

D. T. FISH.

BEDDING PLANTS IN THE PARC MONCEAU.

ONE of the most beautiful and instructive gardens about Paris (says a friend of mine, writing from the Jardin des Plantes) is the little Parc Monceau near the Arc de Triomphe. Its beauty and tasteful arrangement, the perfect order in which it is always kept, and the great variety of choice plants which it contains, make it a delightful resort for Parisians, but especially for those interested in the skilful disposition of bedding plants. I have, therefore, thought that a list of the plants used for embellishing the grounds in 1874 might be of interest to English gardeners. The open places about the shrubberies were given up to such ornamental plants as harmonised best with the adjacent foliage, such as Solanums, Datura arborea, Tagetes, Begonia Evansiana, Iberis umbellata, Dahlias, especially the lili-putian varieties, Antirrhinums, Dianthus plumarius, and D. barbatus, Petunias, Abutilon, varieties with spotted leaves, as A. Thomsonii, A. erectum, A. striatum, &c. There were also many fine Heliotropes and many bright coloured perennial Phloxes, Fuchsias, &c. Judiciously interspersed among the unusually large and effective beds of Negundo fraxinifolia variegata were Roses, Beta purpurea, Amaranthus salicifolius, Tritoma Uvaria, Antirrhinums, and other plants, arranged with much skill, and in a manner most pleasing to the eye; and these, again, were surrounded by ribbons of scarlet Pelargoniums; indeed, most of the shrubberies were edged with some such plants as Pelargoniums, Sedums, Lamium maculatum, Chrysanthemum grandiflorum and frutescens, Veronica Andersonii or V. Lindleyana, Iberis, Lobelia speciosa, and others. Pelargonium peltatum and coccineum did not harmonise well, I think, in this way, and Fuchsia corymbiflora would have looked better in a single row. I would not recommend the ribbon-border style, as the even lines always destroy, to a great extent, the otherwise perfect appearance

of the shrubby margins, nor do I think it advisable, when planting the shrubberies, to make the choice of shrubs subservient to that of flowers when endeavouring to produce a contrast to or rather to suit these cordons. For example, all the marginal plants consist of such species as *Euonymus japonicus*. Perhaps these ribbons were extensively used in order to provide substitutes for tropical or sub-tropical plants, which everywhere find a place on the lawns. There were grown as isolated individuals such plants as *Ferula*, *Bambusa*, *Rheum Emodi*, tall *Dracenas*, *Boehmerias*, *Acanthus lusitanicus*, *Strelitzia angusta*, *Gynieriums*, *Lycopersicum esculentum*, *Phytolacca decandra*, *Palms*, *Solanum marginatum*, *Amorphophallus*, *Struthiopteris germanica*, *Polygonum Sieboldii*. Amongst a number of *Deodars*, fine *Agaves* were planted. Beds were formed of *Cineraria platanifolia*, *Gnaphalium lanatum*, *Begonia viridifolia*, *B. Rex*, and others in a carpet of *Selaginella denticulata*. In the beds, mixed according to size and taste, were the following:—*Ficus elastica*, *Colocasia*, *Cuphea platycentra*, *Phormium tenax*, *Wigandias*, and *Petunias*; while *Dahlias* with variegated foliage, white *Lantanas*, *Erythrin*as, and *Coleus* of different varieties brightened the view. *Saccharum officinarum* was set in the centres of beds, with plants of slower habits around it, such as *Centaureas* and *Lobelias*, *Erythrina*, *Pelargonium peltatum*, with *Iresine Lindenii* and *Herbstii*; *Coccoloba*, *Diervilla*, with scarlet and other *Pelargoniums*, *Königa maritima*, flowering *Lobelias* and *Begonias*, surrounded by *Erigeron mucronatus*. *Magnolia grandiflora*, a fine specimen, was surrounded by tall *Ficus elastica*, so as to form a beautiful pyramid; *Pelargoniums*, *Musa Cavendishii*, and *Coleuses* were found in another bed. *Cereus peruvianus monstrosus* and *Cuphea platycentra* were mingled with *Begonia nitida*, and *Begonias* having scarlet flowers with *Königa variegata*. *Ricinus*, *Tagetes*, *Erythrin*as, and white variegated kinds of *Pelargoniums*, *Aralia japonica*, *Gnaphaliums*, *Cyperus alternifolius* and *Begonia Evansiana*, *Jacksoni*, *Warszewiczii*; double *Heliotropes* were mixed with double *Portulaca*, *Cannas*, *Centaureas*, and red and white flowered *Verbenas*. There were also beds with tree and other *Ferns* and *Aroids*, *Aspidistras*, *Palms*, *Musa Ensete*, with *Sedums* of various kinds. A very fine specimen of rock-work found a place there, the fountain connected with which is very well constructed. The plants enumerated are those which seem to thrive best in the open air in Paris, and can be shown to the greatest advantage if well arranged. A common mistake among flower gardeners is to try to arrange their bedding plants in a formal manner, which reminds one of a clipped hedge. In my opinion no style is better or more graceful than that which gives plants room to grow, and allows each to display to advantage its own peculiar habit.

JOHN BRENNAN.

Loughgall.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Gladiolus præcox.—This pretty little early pink-flowered *Gladiolus* has been blooming with us here ever since December. A potful of it, assorted with such plants as *Triteleia* and *Iris reticulata*, has a strikingly pretty appearance.—T. S. WARE, *Tottenham*.

A Poetical Tribute to the Rose.—A German lady, Countess Prokesch, has collected into a volume all the poems which could be gathered together from the works of German poets in honour of the Rose. It is said that royalty figures largely in this poetic Rose garden.

Campanula Barrelieri, Ferula nobilis, and Sparaxis.—Of these, the first seems quite uninjured by the severe frost (20° here). The same may be said of *Ferula nobilis* and *Sparaxis pulcherrima*. The first is a grand Fennel, the foliage of which had turned a lovely orange-yellow when I saw it at Messrs. Backhouse's nursery at York in September. The *Sparaxis pulcherrima* was in fine bloom there, as was also its still more beautiful relation *Sparaxis pulcherrima atro-purpurea*, a bell-shaped flower of deep mulberry, on long hair-like stalks 4 or 5 feet high. My soil is a heavy clay, but well manured.—FRANK MILES, *Bingham, Notts*.

Primula altaica (syn. grandiflora).—This is flowering well here on a south bank, and is, to my mind, lovelier than any other *Primula*, hardy or otherwise. In colour it is deep mauve, and larger than any other *Primrose*. Cross the *Primrose* with the deep claret *Primula auriculæflora* and the result will be a rich variety of deep violet colour. I am anxiously waiting for a large number of *Primroses*, some crossed by Mr. Dean, of Ealing, but the majority crossed and raised by myself. *Primrose* seed, which should be gathered and sown as soon as it is ripe, is sometimes a long time germinating; it is, therefore, best to sow it in pans, and prick out the larger plants.—FRANK MILES.

A Bouquet of Hardy Flowers.—I send you a few flowers gathered out-of-doors to show how warm and mild it is here; we have not had much severe weather. The thermometer never fell to 20°; we had but one fall of snow, which averaged 6 inches in depth; it remained with us about four days, and on the approach of the New Year disappeared in one night. Since then the weather has been wet and warm, and trees and herbs are filling their buds fast. I send *Garrya elliptica* (the male plant of which is one of the most distinct of winter-flowering shrubs), *Lonicera fragrantissima*, *Berberis japonica*, *Snowdrops*, *Pyrus japonica*, *Jasminum nudiflorum*, and the common yellow *Aconite* (which is generally considered the earliest of all hardy flowers), *Daphne hybrida*, *D. Pontica*, and *Arabis verna*, the latter a little gem which I found growing on the Grampian Hills fifty-five years ago and have grown it ever since.—J. SCOTT, *Crewkerne, Somersetshire*.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Dressing Strawberry Beds.—If these have not yet received their winter dressing, as advised at the close of the year, they should be attended to forthwith when the weather is open. If the soil is of a heavy and retentive nature, it is better to fork over the ground a few inches deep between the rows, without much disturbing the roots, as, if this be not done on such soils, it gets so much solidified by trampling in gathering the fruit that the rains run off instead of penetrating; and if weeds have been allowed to grow to any extent, it is necessary to dispose of them by digging in, for, if hoed up and raked off, so much soil is removed in the operation as to injure the ground and leave the roots bare; but where cleanly cultivation is followed up, and weeds kept down, except in slightly loosening the surface with the object of permitting the rains to pass through, the less the ground among Strawberries is dug the better. Where this shallow turning up is necessary, the spade should never be used, but only the fork. In light soils the hoe is all that is required to destroy weeds, which should be cut off whilst small, and never allowed to get large and numerous, necessitating their removal with the consequent loss of soil that adheres to them, more or less, according as the surface is dry or otherwise.

The Jerusalem Artichoke.—This, with some, is a favourite vegetable. It gives variety through the winter season, when there is not a wide area of choice. It will succeed where most other vegetables will not grow. To the reputation it thus has may be attributed the little attention it receives, and the consequent unsatisfactory state in which it is too often seen. Although somewhat of a surface-rooting plant, it likes a moderately deep well-prepared soil; there is no necessity, nor is it advisable, to select any situation in the vegetable ground for this Artichoke which might be better occupied by something else, yet it should not be planted where the soil is impoverished by the roots of trees or overshadowed by their branches. Dig the ground well, and, if poor, give it a moderate dressing of manure, mixing it well with the soil. Pieces of the tubers about as large as moderate-sized Kidney Potatoes should be planted with a dibber about the beginning of March, when the weather is open, in rows 12 inches apart, with 2 feet between the rows. Cover the plants with about 4 inches of soil; through the spring remove any weeds that make their appearance. When the plants get fairly into growth their dense habit of growth will prevent anything in the shape of annual weeds growing amongst them.

Spring Cabbages.—If there is an insufficiency of spring Cabbages already planted out, more may be planted from the reserve bed, where they were pricked out in the autumn, and which should always exist to supply blanks that occur through the attacks of slugs or other causes. As the ground is cleared from Savoy and Brussels Sprouts, let the old stools be removed, and the place they have occupied dug, always performing this operation—even when going but a single spit deep—well, by getting as deep as the spade or fork will reach. If the ground requires trenching, which it does once in three years, bury the stools and leaves in the bottom. It is a good way to have a rough plan of every vegetable garden, with the crops of the preceding year. This takes very little time to prepare, and is of great assistance in regulating the rotation of cropping, which it is always advisable to carry out.

Rotation of Crops.—Never crop the ground two seasons running with either the same species of vegetable, or with any similar in their habit by being surface or deep rooters. Surface-rooting plants, like all the Brassicas, including Cabbages, Cauliflowers, or Broccoli, are the best to follow such deep-rooting crops as Onions or Broad Beans; plant Lettuce after Celery, and also Peas, for, although the latter are deep-rooted plants, the Celery is an excellent preparatory crop for them, as it is for other vegetables. Potatoes do well upon ground that has grown Strawberries, especially if they were dug up as soon as the fruit was ripe and a crop of autumn Turnips taken from it. Strawberries prepare the ground for root-crops better than anything else grown in the kitchen garden. If a rough plan such as I have alluded to has been prepared and marked whilst the crops are growing, it shows at once, even after the ground is cleared and dug, how to go on with this changing of crops, which it is well to carry out. Where the soil of a garden happens to be too heavy and retentive, it may be much improved, if in a neighbourhood where either pit or river-sand can be had cheaply and in sufficient quantities; a dressing of 6 inches will not be too much, digging it in one spit deep and mixing it well through the soil. Even fine-sifted ashes will improve the texture of such land if applied. The winter season, when the ground is vacant, is the best time for getting it in. Where the soil, on the other hand, is too light and sandy, it is even more necessary to find a remedy, for very light land is ill.

adapted for summer vegetable growing. It can, however, be improved by the application of marl or clay. The former is the best if obtainable, and it frequently happens that in cutting deep drains it can be got at a moderate cost. Good yellow clay is not a bad substitute for marl; whichever is used, it may with advantage be put on from 4 to 6 inches thick, but must not be dug in the ground in a raw adhesive state; the present is a good time for applying it to the surface of land that has not to be cropped until late in the spring, so as to give it the benefit of the weather. March is the best month for pulverising it; it may be put on between the rows of Cabbage plants or on ground occupied with spring Broccoli; 2 or 3 inches placed between the rows of Strawberries on light land will be of the greatest service to them; in short, a dressing of this can be given with very great advantage, either to naturally light gardens or to such as are getting so through the long continued application of stable manure and vegetable matter. In cold, late, exposed situations, not suited for early sowing of Peas in the open ground, a fortnight may be gained by sowing them in a cold Vinery, pit, or frame. Nothing is better than the method of using strips of turf 6 inches wide and about 4 inches in thickness, laid the grassy-side down on borders. Cut a channel down the centre of the turf a couple of inches deep; in this sow the Peas, covering them with fine soil. They will soon begin to grow, the boards preventing their roots descending into the floor of the house or pit; and, when 6 inches high, they can in March be planted in shallow trenches by merely slipping the whole off the boards. If turf is not to be had readily, boards slightly nailed together so as to form a sort of shallow gutter will answer the purpose, or common iron gutterings in lengths, or horse-shoe drain-tiles can be used. In planting, it is only necessary to slip the whole plants and soil entire into the trenches opened for them. Some Celery seed should also be sown in a little heat in pans or boxes filled with fine sifted sandy soil, from which the plants can be pricked out as soon as large enough for handling without injuring their roots, wherein, if the soil in which the seed is sown is lumpy and strong, the roots must necessarily get much broken in moving, which checks the plants, a circumstance that should not occur in the cultivation of this vegetable.

Lawns.—Keep wormcasts regularly swept from lawns, and roll the Grass. For this purpose there is nothing so good as a wooden roller: it should be made of Oak or Elm, and ought to be about 12 inches in diameter and 4 feet in breadth. This will not only keep the surface smooth as well as an iron roller, but it will do away with the necessity of much sweeping; and the labour of rolling with this wooden implement is so much less than with an iron one, that it will not occupy more than half the time.

Gravel Walks.—Nothing adds more to the comfort, as well as the appearance, of a garden than good walks; but, to have these, they must not only be composed of suitable materials, but they must be well made—that is, in the first construction they must be thoroughly drained, properly formed, both as regards the surface and foundations, and the materials of which they are made rightly placed. To make a walk 5 or 6 feet in width, the ground should be excavated to a depth of 12 inches, 2 inches lower at the sides than in the middle; on each side must be a drain, the pipes that form which should be sufficiently large in proportion to the length of the walk, so as to carry off the surface-water in heavy storms, and with a sufficient number of eyes to prevent an accumulation of water on the surface of the walk. A sufficiency of these eyes in walks is more the exception than the rule, through which cause the gravel becomes displaced every time a heavy thunder-shower occurs. In the bottom of the walk place 4 inches of broken bricks, stone-rubble, or ballast—whichever can be easiest obtained; ram this quite solid, on it put on 2 or 3 inches of coarse gravel, and fill up with fine, making the centre of the walk a couple of inches higher than the sides and keeping the grids over the eyes a couple of inches lower, with the surface gradually falling to them; this not only enables the water to run freely into them, but prevents their standing up too high to take it when the surface of the walk gets lowered by gradual wear. A walk so made, if the gravel is good, will always be dry, and in condition to walk upon with comfort, and free from the accumulation of Moss that exists upon walks that are not properly drained. Where walks require re-gravelling, it should be done at once, so that the new gravel may get properly set before the dry weather sets in; this saves an immense amount of labour in rolling, and renders them comfortable to walk upon during the ensuing summer.

Greenhouses and Pits.—Introduce a few more bulbs into the stove, or warm pit, as also flowering Shrubs, such as *Deutzia gracilis*, double *Prunus*, *Kalmias*, and small *Rhododendrons*, *Lily of the Valley*, and also a plant or two of *Azalea*; the white sorts are the most useful for forcing, being more esteemed for cutting. The small purple *A. amœna* is very useful for this purpose, as well as the yellow-flowered *Cytisus racemosus*, which will come into bloom with

little heat. If there have been prepared early in the autumn a few pots of the always acceptable *Mignonette*, a little warmth will assist its flowers to open. Keep these plants near the glass, so that they do not become drawn, and tie them out neatly to a few thin sticks. Go over the plants in the greenhouse every week, removing all decayed leaves and washing the pots when necessary, so as to remove the green mould. Attend to watering, and look over the whole stock sufficiently often to see that nothing suffers through getting too dry. Lilies that are pushing through the soil must now have more water given them. Even when not apparent above the surface, the soil must not be allowed to become quite dry, as the roots are now on the move and require water. Cuttings of *Verbenas* and *Fuchsias* should now be put in to strike. They will root anywhere where they can receive a little heat under a bell-glass in sandy soil. Old *Fuchsias*, that have been dried off in the autumn, may now be pruned. The branches should be cut well in, and reduced considerably in height. They may then at once be placed in heat, and, as soon as they have pushed half-an-inch of growth, may be shook out and re-potted. Soil, if not under cover for the general potting of greenhouse plants, should be placed in a dry open shed, where it will receive plenty of air; lay it as open as possible for this purpose, and occasionally turn it over. Sand, also, should be placed where it will dry.

TREES AND SHRUBS.

MAGNOLIAS.

It is rather early, perhaps, in the season to think about gardening; still, I have been reckoning up the weeks which must pass before the first flowers of spring appear. First will come *Snowdrops*, *Crocus*, and similar low-growing plants, then the pink *Mezereon* and golden *Forsythia*, followed, a few days later, by the showy Chinese *Magnolias*. This reminds me that neither the native nor exotic species of the *Magnolia* are half so plentiful, either in suburban or country grounds, as their merits deserve. Perhaps one barrier to their more extensive culture has been the high price charged by our nurserymen for trees of a suitable size for transplanting; but this in a measure is being obviated by the increase in numbers of propagators, which tends to competition and the lowering of prices. Another obstacle to their culture is the great care required to make the trees live when transplanted; not that the operation is so very difficult, but a certain amount and a certain kind of care is necessary to success. The roots must never be allowed to become dry or in the least shrivelled during the time of removal; neither will it answer to puddle the roots with clay, as frequently practised on more hard-wooded kinds of trees. Then, again, it is not safe to plant *Magnolias* in the autumn, especially in cold climates, where the wounds made on the soft spongy roots are exposed to cold wet earth during a long winter. But, if carefully dug, and as carefully packed in Moss, or well wrapped in some similar material while being transported from the nursery to the place where they are to be set out, followed by ordinary good care in planting, there is very little danger of *Magnolias* dying.

Desirable Species and Varieties.

The Chinese species are, as a class, far more showy than the American, although the trees do not grow as large as some of the natives. *Magnolia conspicua* is one of the very best of the Chinese species, its flowers being large, pure white, and appear before the leaves in spring, making a grand show at a season when one is likely to admire such sights more than at any other. Next to this I would place *M. soulangeana*, which is said to be a hybrid of this and the next. Its flowers are white, tinged or striped with purple, and appear at the same time as the *conspicua*. *M. purpurea* is another of the same origin; but the flowers are purple on the outside and nearly white within, but appear a little later than the first, and before the leaves are fully expanded. A variety of this tree, known as *M. Norbertiana*, has deep purple flowers; otherwise, it is very similar to its parent. *Lenné* is a comparatively new sort, with quite large reddish flowers, which promises to be of considerable value. There are also several other Chinese varieties; but those mentioned above are the best I have seen. Among American species, *M. grandiflora*, of the Southern

States, is a superb evergreen tree, and frequently seen in gardens in the south of England, and in many parts of temperate Europe. *M. acuminata*, better known as the Cucumber tree, grows to a tall handsome tree; and, being a native of the Northern States, it is quite hardy. The flowers are about 3 inches broad, and of a pale yellowish colour, appearing late in spring. It is an elegant rapid-growing ornamental tree, readily propagated from seed, and is quite abundant in our nurseries. *M. cordata*, or yellow-flowered, is a native of the Southern States; but is quite hardy, even in New England. It is a low-growing tree, and not particularly desirable, except as a variety in extensive grounds. *M. macrophylla*, or the great-leaved Magnolia, is not perfectly hardy in the extreme Northern States, but succeeds very well in the Middle States. The branches are very coarse and few in number; the wood is also quite brittle, consequently, when the trees become large, they are liable to be injured by the wind unless growing in a somewhat protected position. The flowers are white and very large, usually from 10 to 12 inches in diameter. A noble, tropical-looking tree, and well worthy of culture. *M. umbrellata*, or Umbrella Magnolia, also called *M. tripetala*, or three-petalled, is a tree somewhat like the last, but the leaves and flowers are smaller. The tree is also more hardy, and grows a little taller, but does not quite equal the next in height. *M. Fraseri*, sometimes called *M. auriculata*, or the ear-leaved Magnolia, is quite a handsome tree, and hardy as any of the species found in the Middle States. Trees suitable for planting out of any and all of these kinds, can be had at our nurseries, and also the sweetest scented, and, I had almost said, best of all, the *M. glauca*, or small sweet-scented Magnolia, also known as Sweet Bay. Common as this shrub or small tree is in the swamps of some of our Northern States, it is far too seldom seen under cultivation. It is my first choice among the Magnolias, and I should try to find a place for "just one more" if it came in my way. The leaves are oblong, deep green above, and whitish beneath, remaining on the plants nearly the entire winter. Flowers are about 2 inches in diameter, pure white, and deliciously fragrant. Plants taken from the swamps are not likely to die if severely pruned at the time of removal.—"Moore's Rural New Yorker." [The last-named species, so highly praised here, thrives freely in England, and is unsurpassed among our flowering shrubs. The specimens at Knowle Park have attained to the dignity of low-spreading trees, and bear numbers of large and fragrant flowers.]

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Starch from Horse Chestnuts.—A patent was granted in the year 1796 to Lord William Murray for his discovery of a method of extracting starch from Horse Chestnuts, and a paste or size has been made from them which is preferred by bookbinders, shoemakers, and paperhangers to that made from wheaten flour.

The Almond Peach (*Amygdalus grandiflora*).—This is a vigorous little tree with branches that are far-spreading and slightly incurved, forming a rounded head. In February and March it produces flowers of a very beautiful rose colour, and large sub-spherical fruit which, however, possesses scarcely any flavour. It is (says M. Carrière in "Revue Horticole") the Almond Peach of some horticulturists, a curious and ornamental form, and, like many others among the *Amygdali*, an intermediate type.

Preservation of Wood.—According to Hatzfield, sulphate of copper gives imperfect and variable results as regards the preservation of wood, because of its solubility in water; and creosote does not fulfil all the necessary conditions, on account of its scarcity and high price. He proposes ferrous acid-tannate. This compound, which is soluble, is transformed under the influence of air into an insoluble salt of an intense black colour; it is deposited in the cells of the wood in a solid state, and produces a sort of petrification which augments the durability resulting from the action of tannic acid alone.

Olive Growing.—In answer to your correspondent "G. R. H." (see p. 42), allow me to say that the best way known here of growing Olive trees is to propagate them by means of cutting fresh bits of wood, with the bark on them, from old clumps at the roots of these trees, something after the manner of cutting up Potatoes for seedling. These bits of wood must be placed in pots and well cared for, till the plant is a year or two of age. The soil in these pots should be moderately rich, and kept moist. Cultivators here usually bury the pots till the plant is well started in growth. When the stem is about the thickness of a finger, the plant should be set out in the place it is to occupy. The soil should be neither too rich nor too poor, and should be well drained. The Olive requires hilly country, where it can have plenty of exposure, and where the climate is dry and temperate, like that of Tuscany. The manure used for it should consist of well-rotted horse droppings, old woollen rags, and chips of leather. The tree will bear a few berries when four or five years old, but the full crop is not produced till the age of twenty years, or so has been attained. The plants should be trained like Lemon trees, i.e., open in the centre, or cup-shaped.—PERSTON POWERS, Florence.

OLD TREES AT FULHAM PALACE.

AMONG the materials at our disposal for the embellishment of residences, it has been rightly said, that none are at once so highly ornamental, so indispensable, and so easily dealt with as trees. Buildings, even unsightly in appearance, by means of judicious planting, may often be made to look highly interesting, provided trees suitable to the situation are selected and properly planted. Architects often plant such surroundings badly, owing to a want of knowledge of the materials with which they have to deal, the proportions they will attain, and the ultimate effect they will produce, when fully grown. Fulham Palace, as will be seen by our illustration, is a plain unpretentious building; nevertheless, for its deficiencies in the way of architectural embellishment, we have ample compensation in the fine trees by which it is surrounded. On the left of the house is a venerable Cork tree, which for centuries has withstood the tear and wear of time, the imprint of which is strongly impressed on its great trunk, from which, at least one aged arm has been separated, and, as will be seen, has been used as a support for the main body of the tree. This tree was planted about the end of the sixteenth century, most probably by Bishop Compton, whose skill as a planter, and perseverance as an introducer of American trees, are well-known. The tree on the right which has been planted as a companion to the old Cork tree, is the Robinia or False Acacia, of the great value of whose wood Cobbett long ago wrote in such extravagant terms. No place in England contains so many full-grown Virginian trees as Fulham Palace, and most of them have been raised from seeds sent to this country by the missionaries who first went to North America in Bishop Compton's time. The spot on which these men first preached to the native Indians near Richmond, in Virginia, is now the site of a mansion, in front of which are two trees of the White Oak (*Quercus alba*), placed so as to balance each other, just like the two trees at Fulham, as shown in the illustration. The trunk of one of these Oaks I measured, and found it to be, at 3 feet from the ground, 21 feet in circumference; the other was 18 feet in circumference. These trees cover so much space, that if they had been planted anywhere near the building, they must have been removed long before full beauty had been reached. At Fulham, we get a notion of the colossal dimensions which these American trees acquire when fully grown, and therefore intending planters who have not seen them in their native country, as I have done, will do well to inspect them before commencing operations, especially such as have to plant in the neighbourhood of buildings. At Fulham, too, may be seen a flat piece of ground, consisting of some 30 acres, rendered interesting wholly by trees; by their aid objectionable features are shut out, and others of a suitable character are brought into view, and altogether as much variety is thus secured as is to be found in the most extensive estate or domain in the country. Conspicuous among the trees employed for this purpose may be named a Hickory, which has a trunk 16 feet in circumference, and 15 feet in height, clear of branches. It then divides into two huge limbs, each 80 feet in height. The Hickory becomes exceedingly beautiful in autumn; the leaves, which during summer are of a bright airy green, turn yellow as the season advances, and hang upon the tree for a month or six weeks after the change takes place. No tree, indeed, even in its native country, is more strikingly beautiful in the fall than this, especially when associated with Liquidamber and scarlet Oaks or silver Maples—all trees remarkable for fine colours. Of the black Walnut, which is one of the most useful of American trees, and one which is now becoming scarce even in Virginia, so much is its timber sought after, there are here fine specimens, as well as of American Oaks, especially the white one, a tree of which measures, at 3 feet from the ground, 12 feet in circumference; the wood of this Oak is almost as elastic and valuable as that of the Hickory, and, indeed, the white Oak is considered to be one of the very best of American timber trees. Of the Tulip tree, one of the best specimens in the country stands on the lawn at Fulham, and among trees possessing beauty of another kind may be named the *Gleditschia triacanthos*, or Honey Locust, so named on account of the sweet pods which it bears; the spines of this,

VIEW IN THE GARDENS AT FULHAM PALACE.

which are long and formidable, are associated with foliage almost as light and pretty as that of the Sensitive plant. Of the Judas tree there is here a fine standard, and also a grand old Cedar of Lebanon, from a seat beneath which a pretty little flower garden is overlooked. These, and many other trees, too numerous to mention, are set in an irregular framework of splendid Elms, both in the adjoining park and on the banks of the Thames. Vistas have of late years been cut through the boundary line, so as to bring in occasional glimpses of the Thames, and in this way increased interest has been given to the place. Around the whole of the ornamental department is a well kept gravel walk—tortuous here, straight there, but so managed as to give the visitor to the grounds an idea of extent considerably beyond that which they actually possess. The lawn boundary has been framed by a master hand—here bold and projecting, there deep and shadowy; at one point glowing with colour, at another depending for beauty on leafage only, and the whole, when in full summer beauty, forming one of the most charming pictures to be found anywhere. JOSEPH NEWTON.

LARGE BOILERS AND FURNACES BETTER THAN SMALL ONES.

I CAN fully corroborate all that Mr. Fish says (see p. 58) with regard to the wisdom and economy of having plenty of boiler power in proportion to the amount of heating required. The first outlay in putting in a larger-sized boiler is very soon saved in fuel. A small boiler has not the capacity for taking the same amount of heat from a given amount of coal that a larger one has. The same rule more than holds good in reference to the amount of piping that is laid in the house to be heated. I had a very striking example of this in these gardens this winter, with the thermometer repeatedly near zero; the only boiler that required to be at all driven to do its work (the whole of the boilers being castings from one mould, and circumstanced alike in all respects) is the one with by far the least piping attached to it—the reason of this being that the houses it heats have less piping in them than the others, and had to be made much hotter in consequence. Ample boiler power and ample piping are the great secrets of economical heating. Regarding the levels at which boilers should be fixed in relation to the pipes, I have proved that if the return opening into the boiler is below any other portion of the pipes to be heated, it does not matter if the flow opening is above the body of the pipes. One of the most efficient heating apparatuses I ever worked had the flow pipe starting down hill immediately it left the boiler, but at no part did the water descend below the return opening into the boiler. Looking at the law of hot-water circulation, I should say that such an arrangement was sound, for, immediately the water leaves the boiler, it begins to part with its heat; cools, and becomes of a greater specific gravity; and surely, from that fact, its natural vent is down hill, not up. And I conceive it unnecessary expense to excavate deeply into the ground for the mere sake of getting “a good rise from the boiler,” as is so often spoken of. I can endorse what Mr. Fish says about the undesireableness and waste of small furnaces. In arrangements recently carried out here, I have had furnaces made 19 inches deep, and 21 inches wide. The boilers form the furnaces, the said boilers being a combination of the saddle and cruciform, and are 6 feet long. A small furnace requires a smart firing draft, to give the same amount of heat that a larger body of coal gives with less of a draft. For, with a large body of hot glowing coal, the doors and dampers can be so regulated as to cause a red mass of fuel to lie for hours in a condition to give off a powerful heat. A larger body of fire requires to be less often fed, and the fire is more constantly “red hot;” whereas a small furnace requires to be going at high pressure, and be often fed, and the waste of coal and heat is greater. The larger furnace can be left a longer time safely without attendance. I cannot agree with Mr. Fish in saying that the shape of the boiler is of less moment than its size. I think the shape of a boiler important, and those boilers that give most heating surface in direct contact with the fire I have always found to be the most powerful. The more of a boiler that

is licked with flame, and against which most glowing red coal rests, must surely be the best, and shape has more to do with this, I think, than size. Not an atom of brick should form any part of the furnace or fire-place of a boiler. It should be water above, below, and at the sides; and, besides, a large boiler-surface in direct contact with the fire, the draught should traverse about every inch of the boiler two or three times before it is allowed to escape with such an enormous amount of heat into the flue or chimney. D. THOMSON.

Drumlanrig Gardens.

YOUR correspondent, Mr. D. T. Fish, has called attention to a very important matter, for the late severe weather has brought home to most of us the necessity and great economy of having boilers of sufficient power to cope with such seasons without much extra strain. Even with these it is often lamentable to see the great waste that takes place through unskilful stoking. This is almost as important a matter as having efficient boilers; for it is easy to get the same amount of heat in the pipes with much less fuel than is generally used, if the stoking be conducted with a little more thought and skill. It is but too common a practice with those in charge of fires to have ashpit-doors and damper wide open, thus admitting a large body of cold air through the furnace that carries the heat up the shaft with a rush. If this damper were used, as it should be, to keep the heat playing slowly over the surface of the boiler, much waste would be avoided. It frequently happens that fires are allowed to get too low, and then twice as much fuel is thrown on as is necessary. This leads to the ashpit-door and damper being thrown open to quicken combustion, with the results I have mentioned. With some boilers the fiercest heat is spent in solid brickwork, as was the case here till I had the furnaces lined with 2-inch tubing. These were placed 1 inch apart, and the furnace bricked up at about 2 inches behind them, so as to allow the fire to play right round the tubes. The result has been most satisfactory, as the power of the boilers has been nearly doubled. One furnace contains four of these tubes along each side and back, and the other three; and, as these encase the fire, it will be readily seen how serviceable they are. Boilers should be always so constructed that the fire is fully encased by water, as every brick or other surface not containing water that is exposed to the action of the fire is robbing the coal-heap to no useful purpose. Whatever the form of the boiler, and however fiercely this heat may play on any particular part, the hottest water will be always at the highest point—the top of the boiler, and this is the proper place for the flow to commence. To carry a flow-pipe with a vertical dip must greatly impede the circulation, and lead to loss of heating power. The tendency of all heated liquids is to swell and ascend, and it is of the greatest importance that the top of the boiler should be lower than any of the flows. I quite agree with your correspondent, that every boiler should form its own setting, and that the more the surface that is exposed to the direct action of the fire can be corrugated, so as to increase the heating area of that particular part, and break up the flame, the more powerful and valuable will the boiler be. The first cost of a good boiler being heavy, cheap and inferior ones are often used instead, and these are dear at any price, as they entail a continual outlay for extra fuel that would have been saved by the purchase of a good boiler at starting. There are so many good boilers, that it seems invidious to particularise any single make; but, for moderate cost and real efficiency, the terminal saddle, having tubular bars, is one of the very best, as it entirely encases the fire with water. If the arch of this boiler were only corrugated, it would leave little to be desired; and boilers of this kind can be set in shallow stokeholes, which is an additional recommendation. Besides having boilers of sufficient power, it is of the greatest importance to have plenty of piping, and the economy of this must be apparent to anyone, as it will of course require the water twice as hot in one pipe as it would if two were used to do the same work. If, therefore, we would reduce the yearly cost of coal, it can easily be done by having an efficient boiler, a careful stoker, and plenty of pipes. J. S.

Woolverstone Park.

Wax-yielding Plants.—At a meeting of the Natural Science Society recently held in Hamburg, Mr. G. Wallis remarked that wax was not only obtained from the berries of *Rhus succedanea*—a plant which also supplies the celebrated Japan lacquer, the preparation of which remains a secret—but that three other kinds of wax from entirely distinct trees are known to be obtained in South America. One comes from Northern Brazil, and is produced by the beautiful *Klopstockia cerifera*—called there *Carnauba*—which grows between the fourth and sixth parallels of southern latitude. Another kind is obtained from a *myrica* from Peru and New Granada,

which passes there under the names of Laurel and Olive. This tree grows in a variety of situations, and even at elevations of 5,000 or 6,000 feet above the sea. A third kind of wax is derived from a tree which, up to altitudes of 10,000 feet, grows in the same republics—viz., the Ceroxylon, or Wax Palm. The methods of obtaining the wax from these trees differ greatly, but its subsequent preparation for the manufacture of candles is, in all cases, the same. In the Klopstockia it is obtained from a dusty coating on the leaves. In the Myrica as well as in the Rhus succedanea, it is obtained from the berries, and in the remaining instance it is taken from the stem, which is clothed with a thin mantle of wax, and this is scraped off with an instrument made for the purpose. Mr. Wallis stated that a manufactory exists in Brazil for working the wax into candles, of which he had seen fair specimens made from the Carnauba and Laurel kinds. One great drawback is the bad colour of the wax, for bleaching which no process is known. The Brazilian kind is green, the others rather of bluish or light yellow tints. Large premiums have for years been offered in Brazil for the discovery of a process that will effectually whiten the wax; but as yet they have not produced the desired effect. In Japan they appear to have some process by which it is bleached, but it is doubtful whether it has not already been tried in Brazil. The Ceroxylon produces the whitest wax; but all kinds suffer more or less from a want of consistency, which, unless they are mixed with other substances, renders them useless for the manufacture of really superior candles.

Silica not Essential to Plant Growth.—The idea originated with Sir Humphrey Davy that the siliceous or silica of the soil must be dissolved by the help of alkali, and must enter the plant in order to stiffen the straw of our grains. That idea was thrown out by Davy, not as a positive assertion, but as a suggestion. Knowing that silica was abundant in the slender stems of cereals and grasses, and is but a small ingredient of other plants, he suggests that the silica might serve the office of stiffening the straw, and act as the skeleton of the plant. The facts which demonstrated the falsity of this idea were developed by two of the agricultural investigators of Saxony, viz., by Dr. Julius Sachs, formerly of the Royal Saxon Academy of Agriculture and Forestry, at Tharandt, and by Dr. Wilhelm Knop, of the University of Leipsic, and for some years director of the Moekern experiment station. These gentlemen at the same time, but independently of each other, made numerous trials on the feeding of plants, by stationing their roots in simple water, in which the substances presumed to be needful for growth were dissolved. By this method of operating they could add or exclude any single or several elements to any desired extent, and thus learn the effect of their presence or absence. They found that potash, lime, magnesia, iron, phosphoric acid, sulphuric acid, chlorine, nitric acid and water, united so as to form a very dilute solution, containing not more than one or two-thousandths of solid matters, was able to nourish various plants, and among them Oats and Maize, as perfectly as a rich soil. The solution thus made contained only the minutest quantities of silica, and plants thus produced contained less than one-thousandth of their weight of silica, and yet their strength was equal to that of field-grown corn, containing one and one-half per cent. The trials have been repeated by at least a dozen other experimentalists, and always with the same results. Thus we know positively that we need not trouble ourselves to manure with silica, or to treat the soil for increasing the supply of it; the plant does not require it for strength. Silica enters the plant because you cannot keep it out. The very fact of its extreme variability in the same kind of plant, grown in the same kind of soil, while potash and lime are much less variable, and phosphoric acid is almost an invariable quantity is a sufficient indication that it is not an essential element to the plant.—
PROFESSOR JOHNSON.

Home-grown Tobacco.—The most successful method I know of preparing home-grown Tobacco (see p. 60) is to sow the seed in gentle heat in March. When up, and large enough to handle, prick out the plants in boxes or pans, or pot them singly in small pots, and grow them on until they have filled the pots with roots. It is not desirable that they should be starved before being planted out, which should be done either in May or June, after having been hardened off in the usual way. The best place for planting, especially for those whose space is limited, is between the Asparagus beds, as the roots will then be partially shaded from the hot sun; the soil will be rich, and the plants will soon reach their full size. The best time to commence operations will be as soon as the plants are in flower. The plants may then be pulled up by their roots, and brought together to the potting shed, or some other convenient place, and all the leaves can be stripped off the stalks. They must then be placed out singly, or nearly so, in the full sun, but not on the damp ground. I have found a Quick hedge or a stone wall answer admirably. They become flagged or shrivelled by evening, and they must then be packed (a hamper is the best thing for this), pressed firmly and closely together in layers, and remain there until they commence to heat, when they must be placed out again in the sun. Care must be taken that they are not allowed to remain too long in the hamper after commencing to heat, or they will become mouldy. This must be repeated until the leaves have become quite dry. Nothing now remains but to pack it away in a dry place until required for use. If this system be adopted, your correspondent will be rewarded by a plentiful supply of highly-coloured and highly-perfumed weed.—J. S., Bradford, Yorkshire.

THE GARDEN IN THE HOUSE.

VASES OF FLOWERS.

MANY kinds of flowers are now attainable for floral decoration, and amongst the vases that I have lately arranged myself was one, the bottom of which consisted of a flat glass dish or tazza, raised on a pedestal about 4 inches high; from the centre of this rose a slender glass trumpet, also three spirals of glass, which curved outwards when about 12 or 14 inches above the tazza, and each of these supported a small glass basket. This was for a table ornament in the drawing-room, not for the dinner-table, a purpose for which it would have been useless, as the baskets would have interrupted the view across the table—a point always to be avoided. In the tazza I placed three blooms of *Calla æthiopica*, and, between each of these, sprays of a pinky-mauve-shaded *Primula*, and some Cape Heaths. Round the edge were fronds of the following Ferns:—*Adiantum pedatum*, *Pteris serrulata*, and some golden and silver varieties, so placed as to show the backs of the fronds; while placed so as to “wave out” over the flowers, and, as it were, half shroud them, were three large fronds of Maiden-hair Fern (*A. cuneatum*). In the little suspended baskets I placed sprays of white *Epacris*, and *Cyclamen* of the same shade as the *Primulas* in the tazza, and interspersed throughout the whole was Maiden-hair Fern. In the trumpet were mauve and white *Cyclamen*, Heaths, Roman Hyacinths, and Ferns; and three long sprays of *Lygodium scandens*, which drooped down and mingled with the flowers in the tazza below. The next arrangement which I shall describe, consisted of a basket of flowers, also strictly a drawing-room ornament. It was of white china, of an elegant and graceful shape, and was fitted up with Yellow Allamandas, mauve *Cyclamen*, *Cinerarias*, *Caladium* leaves, and mixed Ferns. The *Caladium* leaves were small in size, and stood up above the flowers with excellent effect. The only drawback to such leaves being introduced into floral arrangements is, that if the plants have not been hardened off previously to being cut, they are apt, when subjected to a dry heated atmosphere, to curl and shrivel, a condition which gives the whole arrangement a faded aspect. The next stands to which I shall allude were large-sized specimen-glasses, a few of which, placed here and there about a sitting-room, and tastefully filled with flowers, form as pretty decorations as any, and they require but few flowers; in fact, more than a dozen of them could be filled with the same number as would be required to fit up the smallest sized stand of the March type. I have seen a few lately fitted in the following manner:—In one was a white *Camellia*, a sprig of scarlet *Geranium*, some spikes of Roman Hyacinths, and fronds of Maiden-hair Fern; another consisted of a yellow Rose-bud, scarlet *Geraniums*, and Ferns; another of a *Gardenia*, some fancy *Pelargonium* blooms, Roman Hyacinths, and some Fern fronds. On Christmas Day, amongst other vases, I arranged four of this shape for placing on the drawing-room mantel-piece, and employed the following flowers:—One contained a large *Gardenia*, some blue *Nemophila*, spikes of white *Epacris*, and Maiden-hair Fern; another, a white *Camellia*, pink *Geraniums* (Christine), pink Heaths, and Ferns; a third, mauve Orchids, Roman Hyacinths, and Maiden Hair Fern; and a fourth, a yellow half-blown Rose-bud, scarlet *Euphorbia*, and white *Cyclamen*. Single blooms can be placed in these glasses if preferred, but in that case the glasses should be of smaller size than any of those just enumerated. If single blooms be selected, they should be of choice varieties and perfect specimens of their kind, such as a handsome *Eucharis*, Orchid, *Gardenia*, Rose, or *Camellia*, and they should always have plenty of Maiden-hair Fern associated with them; in fact, each bloom should be set in a little bower of greenery, and a tiny spray should be drawn across the bloom, so as to tone down and at the same time set off the flower thus situated. Many often hesitate to use much Maiden-hair Fern in their floral arrangements, under the impression that fronds of this Fern last but a short period; this is, however, a mistake, as, if the plants from which the fronds are cut be well hardened off beforehand, they will last quite as long as, if not longer than, the flowers with which they are associated.

A. HASSARD.

THE INDOOR GARDEN.

FORCING FLOWERS.

IN forcing, the first consideration for amateurs should be to secure plants of full and decided maturity and in perfect health, if not luxuriant, for it will invariably be found that the beauty of the flower will depend very much on the growth of the previous year, and, all other circumstances being the same, will be rich or meagre, in exact proportion to its vigour. Then the plants intended to be used should be thoroughly established before they are introduced to a warmer atmosphere, otherwise they will not have acquired the means which are necessary for immediately supplying aliment to meet the demands of an increased circulation. Amongst the plants usually selected for forcing, the bulbous-rooted and herbaceous, which form an entirely new set of organs every year, may be

fortnight will generally be long enough, the hard-wooded may be kept a little longer, and then introduced to the stove. In the ordinary development of the organs of a plant, growth first commences at the root and proceeds gradually upwards, as we may observe in the bursting of the leaf and the formation and expanding of the flower-bud. Now, under these well-known circumstances, it would be absurd to place a plant into a high temperature at first, for then the action would commence at the stem, or above the roots, and, of course, the result would be an abortive production of leaves or flower-buds, caused by the inaction of the roots and want of necessary food. Another necessary point to be observed in forcing is a judicious supply of water; as a rule, it will be safe to regulate it according to the supply of heat, commencing with a limited supply at first, and increasing it with the increase of temperature, resulting in a full supply every day at the period of blooming. Of course some plants require larger supplies of water at all times than others.

Tillandsia musaica.

introduced into heat after a few weeks establishment in pots, but such as Roses, Rhododendrons, and other hard-wooded plants which have a more persistent system, are absolute in requiring to be potted at least six months before any successful attempt at forcing can be made, so as to allow them to form a season's roots. Having the selected plants properly prepared, the next essential is the manner in which the necessary heat is applied, for any misapplication in this respect will render the previous labour and expense useless, and result in loss and disappointment. The increase of heat should be brought on gradually, so as to resemble as nearly as possible the advances of spring, which forcing is intended to anticipate. It is always better that plants intended for forcing should never feel the effects of frost, however hardy their natural constitution may be, and for that reason they should be early put into a cold frame, at a temperature of not less than 35°; then, according to the time they are required to flower, they may be introduced into a greenhouse temperature of 45°; the length of time they are kept there will depend on the nature of the plants; for soft-wooded and herbaceous kinds a

When blooming, it will be advisable to remove them to a cooler house and supply less water.—“Gardener's Record.”

TILLANDSIA MUSAICA.

As a fine foliage plant of distinct habit and tolerably easy culture, this has but few equals. The broad strap-shaped leaves are of a bright green tint, transversely banded with deep green and brown, or purple, markings, well shown in the accompanying illustration. In its native habitat, it is found growing in moist, partially-shaded situations, at about 5,000 feet above the sea level. It grows nearly equally well on the trunk of trees or in a rich leaf mould, the result of an ever changing tropical vegetation. The plants appear to be exceedingly difficult to import alive, and seed is difficult to obtain, owing to its becoming ripe at the commencement of the rainy season. It requires a moist and equable stove temperature, and succeeds best in a rich compost of Sphagnum, leaf mould, peat, and sand. Mr. Bull was one of the first in Europe to obtain living plants of it, and it suc-

ceeds well in his establishment among other choice foliage plants. The flowers are said to be extremely ornamental, but have not yet been produced in this country. B.

A GOOD METHOD WITH PERSIAN CYCLAMENS.

RAPID strides have been made within these last seven or eight years in the culture of this, the Queen of winter decorative plants. A well managed group of Cyclamens was at one time rarely met with; but since its growing capacity has become better understood, it forms one of the foremost attractions at our early winter and spring floral exhibitions, and in the metropolitan flower markets, where, perhaps, it commands a more ready sale and a higher price than any other plant grown for decorative purposes. It is a valuable auxiliary in establishments when large conservatories or rooms have regularly to be supplied with a numerous assortment of forced plants in pots during winter; and it is indispensable where cut flowers are in demand for vases and bouquets. The sweet-scented kinds are highly esteemed for the latter purpose, and, from the fact of their being of such easy culture, I consider that they are a class of plants well adapted to the requirements of amateurs. Their peculiar mottled foliage, and the long duration of their bloom, render them a never-failing source of interest and pleasure, which is well worth any extra pains that may be bestowed on their culture. From October until Christmas being the dullest portion of the year for flowering plants, I always aim at getting my first batch in at that time. To effect this let them be sown as early in October as possible, in a well-drained pot or pan, previously steeping the seed, which is unusually hard and slow in coming up, in moderately hot water, and placing a pane of glass over the pan, which should then be placed on a shelf near the glass in a warm house or stove, if such be available. Germination will take place in about a fortnight, and the pane of glass must then be removed from the pan to prevent damping off, and also drawing. In about six weeks from the time of sowing I pot them singly into small pots, and replace them on the shelf as before. In the February following I shift them into 48-sized pots, choosing, this time, a compost composed of equal parts of friable loam and dried cow-dung, with a heavy admixture of sharp river sand; I have often tried other mixtures of potting mould, but found none to answer so well as this. From this time I grow them on as briskly as possible until the 1st of May, when they are transferred to a pit or frame, and gradually hardened off, prior to being turned out of the pots and planted about the middle of the month; this, however, must of course depend upon the weather. A north border I find to be the best position to plant them out in. Let the ground be well dug and thoroughly well pulverised, and heavily dressed with rotten manure and plenty of rough sand. Avoid planting them too deeply; keep at least three parts of the bulb well above the surface. I consider this manure dressing to be of paramount importance, providing, as it does, a cool and rich bottom, which is so congenial to the Cyclamen during the hot summer months. A good watering once a week, and a sprinkling with a fine hose or syringe once a day to keep down insect pests, is all the attention they will now require. In the middle of August take them up with a fair amount of soil or ball attached, and pot them in 32's, or Strawberry pots as they are called; use the same compost as that recommended for February potting, and remove them to a pit, paying due attention to watering, shading, &c., for about ten days. By the middle or end of September the pots will be found to be crammed full of roots, when they may be placed in the greenhouse in a position as near as possible to the glass. In adopting this easy method of culture I have been well repaid this winter by as fine a lot of plants for their age as I have ever seen. I formerly sowed them in January and bloomed them in ten months, but I find the twelve months' system the best. My success in this direction has been much augmented by the kindness of Mr. Edgerton, gardener at Strawberry Hill, who some years ago presented me with a selected packet of seed from his famous collection grown at that place. T. P. T.

[We have seen the Cyclamens in the open air in summer, as described by our correspondent, and they were very well and simply grown.]

GARDENING FOR THE WEEK.

Hardy Flowers, Alpine Plants, and the Wild Garden.

The value of our hardy border plants is now duly recognised in the majority of gardens. They are no longer looked upon as outcasts, and as such consigned to some out-of-the-way corner of the grounds, where, in years gone by, they were entirely neglected, and left alone in their struggle for existence. This treatment could have but one result. The weaker plants succumbed; all but a few of the most vigorous and least useful disappearing. What, then, is the best position for an herbaceous border? In olden times, these plants used almost invariably to be arranged by the side of the walks in the kitchen garden, nor have I the least objection to their occupying such a position even now; but the appropriation of such borders to pyramid trees has rather interfered with the olden style. As these have to undergo the operation of occasional root-pruning, it will be obvious that these borders have lost their value for such a purpose, added to which trees interrupt the continuity, which is one of the most important features of a well-arranged herbaceous border. For my part, I prefer a border of this sort to be situated in the pleasure-grounds, with an aspect fairly open to the sun, and not overshadowed by trees. It should be about 8 feet wide, and backed up by a bank of evergreen shrubs. This is a more important point than many people might suppose, and one which it is out of the question to expect where the old kitchen garden arrangement is carried out. There the best backing, and one that used often to be adopted, is a row of Sweet Peas; but a backing of this nature is necessarily of a temporary character, and lacks the repose which a back-ground of evergreen shrubs gives. Even the colours of our most brilliant flowering plants are more effective when seen against a back-ground of those varying shades of neutral tints which are available in our mixed shrubbery. For example, how much more beautiful Hollyhocks appear where they rear their monumental stems, like so many floral columns, amongst the surrounding greenery than when seen against the sky line. There are few places where a border of this sort cannot be formed. It is by no means necessary that it should be straight; a good bold sweeping curve is, in some respects, preferable, as it reduces stiffness and formality, which, if not entirely dispensed with in an herbaceous border, should be a matter of secondary importance. Having selected a border as suggested, the next point will be the character of the soil. If it has been found necessary to invade the lawn all the better, as the majority of these plants have a peculiar liking for fresh soil; indeed, all plants have, unless it be some of our nitrogenous-loving weeds. After the removal of the turf, for which a use is almost sure to be found in any garden, test the drainage, and be sure that there is no danger of any part of the border becoming waterlogged; rather put in an extra drain than run any risk, and let the drains be, if possible, 3 feet, or even more, below the surface, as the roots of all plants, and more especially the class of plants for which we are making provision, are particularly partial to these aerial arteries. The drainage having been completed, and, in the process, the character of the sub-soil tested, a pretty correct opinion may be formed as to what admixture will be necessary. If the soil be a strong clay, I should, instead of removing a portion of the clay and replacing it with good loamy soil, prefer to raise the border, by any addition you may deem it necessary to make, to a height of 12 or 15 inches at the back. Of course there may be exceptions; but, as a rule, herbaceous plants like a tolerably stiff and retentive soil. The front of the border, where the dwarfer and more delicate-rooting plants will be placed, may require some of the sub-soil taking out so as to secure a depth of about 12 inches above the clay bottom. This done, give a good dressing of well-decomposed manure, such as an old Mushroom-bed will furnish; and, if available, an equal proportion of leaf soil, and about a barrowful to every 2 linear yards of border of old mortar or plaster from any old buildings, or, failing that, the same quantity of sand. Dig over the whole to the full depth of soil, so as to thoroughly mingle the materials together; it must then be left loose as dug till the first or second week in March, when it will have settled under the combined influence of frost, snow, and rain, and be in a condition for planting. If the soil be of a light sandy nature, and, as is frequently the case, lying on a gravelly sub-soil, I should strongly advise the removal of a portion of the gravel by trenching, and, if it be at all possible, the use of an equal amount of strong soil, even if at some outlay, and incorporating this with the natural soil—adding manure of a somewhat stronger character than recommended under the previous conditions, and omitting the leaf-mould and the mortar-rubbish as unnecessary in this case. I have presumed that the grassy side of the shrubbery, plantation, or whatever it may be, has been selected; but circumstances may occur in which it may be more convenient to remove some of the shrubs, so as to obtain the necessary width of border. In this case the treatment will be different. Of course my remarks on drainage will hold good, but the

ground must be trenched at least two feet deep; in the bottom of each trench, as opened, 4 or 5 inches of any strong manure may be placed, without paying attention to its thorough decomposition; and as the first spit of soil is turned over on the top of the manure, it should be trodden pretty well down so as to give it firmness. The trenching process being completed, a surface-dressing of materials the same as those previously described, but varying according as the soil may be of a heavy or light sandy nature, should be applied and lightly forked in. In this case the ground having been disturbed to a depth of 2 feet before any planting is done, it will be well, even though a couple of months intervene between the formation and the final planting, to tread the border well over and thoroughly consolidate it, as herbaceous plants like a firm root-hold. Light surface soil tends to surface rooting, and thus incapacitates plants from passing unscathed through even a moderate drought.—JAS. C. NIVEN.

Flower Garden and Pleasure Grounds.

Finish as soon as possible the planting of evergreen and deciduous shrubs and trees, and as soon as this has been done, the soil, if at all heavy on account of the necessary treading upon it during the operation of planting, will probably be found to be in a somewhat consolidated condition; and should wet weather prevail, this may cause accumulations of stagnant water. To prevent this, let it be loosened up with a spade, or, what is better, with a light fork, which will leave it in a loose and friable condition. As previously advised, proceed as rapidly as possible with alterations of all kinds, whether they may consist of the formation of flower-beds and borders, the making of walks, levelling and laying of turf or planting of Box, and other edgings. The planting of hardy herbaceous perennial plants may also be proceeded with, and these plants may be furnished by the reserve garden, or they may be obtained by the division of large and established plants. There are now so many really valuable hardy herbaceous and Alpine plants well suited to this purpose that many of the tall coarse-growing species may with advantage be discarded, as a judicious selection of really decorative plants, well attended to, is certainly more to be desired than a collection of greater extent containing plants worthless as regards decorative effect. A somewhat liberal use, however, may be made with safety of such genera as the *Delphinium*, *Dianthus*, *Myosotis*, *Pentstemon*, *Phlox*, and *Iris*. Wherever it is desired to indulge in the style of gardening known as sub-tropical, the seeds of various kinds of plants used for this purpose should be sown now, in order that they may be had sufficiently strong when the time arrives for planting them out. Such seeds should, of course, be sown in heat in seed-pans, and the plants should be potted off singly as soon as they are large enough to be handled, and grown on as rapidly as possible. They may consist of the various *Ricinus*, *Cannabis gigantea*, *Nicotiana Wigandioides*, *Solanum Warscewiczii*, &c.; while dry roots of the *Cannas*, *Brugmansias*, &c., should be at once placed in heat with a view to increase by cuttings or divisions. Such plants as the *Humea elegans*, so useful for decorative purposes, should be sown in September, and potted off singly during the autumn; they may now require to be potted into larger pots, as, if they are allowed to become pot-bound, they will invariably lose their lower leaves. Pot off also rooted cuttings of choice *Hollyhocks* which may have been inserted during last autumn into pots some 4 inches in diameter; keep them close for a few days, and, when fairly established in their pots, they will only require the protection of a cold pit or frame until the time arrives when they may with safety be planted out where they are intended to flower. Proceed at once to increase bedding stock of all kinds, in accordance with what is likely to be required. Spring-struck cuttings of such plants as the *Verbena*, *Petunia*, *Ageratum*, *Coleus*, *Iresine*, &c., are all much to be preferred to those struck during the previous autumn, which it is advisable to throw away when sufficient cuttings have been secured from them, and such cuttings should be inserted in well drained pots, some 6 or 8 inches in diameter, using a soil composed of sifted leaf soil, and river or silver sand; place the pots containing them in a gentle heat until fairly rooted, when they should be gradually inured to the temperature of an ordinary greenhouse pit, with the exception of the two last-named species, which will, for some time longer, require to be kept in a higher temperature, but in no instance is potting-off singly necessary. Spring-flowering plants and bulbs will soon begin to attract attention, so keep the beds and borders containing them free from weeds and littery matter of all kinds. Remove litter or worm-casts from the lawns by frequent sweeping, and pass a heavy roller over it as often as possible, while the same should frequently be done with gravel walks, in order to render them firm and comfortable. At this season the gravel, when somewhat moist, is apt to adhere to the roller; and, to prevent this, let a faggot of dry wood be burned inside the roller just before using it for this purpose.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Trees and Shrubs.

Push on the planting of all kinds of deciduous trees and shrubs, as the buds are fast swelling, and this kind of work should now be brought to a close as soon as possible. After planting, all should receive a good mulching of half-rotten litter, and, if in situations where the appearance of this is likely to be objectionable, scatter a little fine soil over it, and this will prevent it being blown about. In planting for effect, make choice of elevated positions, and group together plants that are of similar feature, or type, of vegetation, and associate well together. By taking advantage of elevated ground, and planting, on the summit, only trees that grow to a considerable height, and, on the foreground, trees of the same type, but of lower growth, the hills are, as it were, uplifted, and the valleys depressed. Trees should never be planted in a hollow, but on the summit or side of hills. In such positions, they always look more natural, and show off to greater advantage. Planted in this way, they are not only much more effective, but help to bring out any slight undulations in the ground in the most favourable manner. For groups in park scenery, or near mansions in pleasure-grounds, few things are more striking or ornamental than the Scotch Fir (*Pinus sylvestris*). Their bright-looking polished bark is always attractive, and their towering majestic height and form invariably command admiration. The Maiden-hair tree (*Salisburia adiantifolia*) is a highly ornamental tree for pleasure-grounds, and it is singular that it is so seldom met with. Its light green elegant leaves are only excelled by the favourite Fern it resembles, and from which it derives its name. It appears a little fastidious as to soil, as I have never seen it good except on stiff deep land. Although, as a rule, I am not in favour of transplanting evergreens at this season of the year, if the weather continues mild, *Aucubas*, *Rhododendrons*, *Box*, and plants of this kind, that always lift with good balls of earth, may be moved with comparative safety; and there may be special reasons why such work should be done now. When such is the case, those trees that have been so frequently removed as to have induced plenty of fibre, may be operated upon with every prospect of success, provided February and March do not turn out too cold and cutting. April is, of all others, the safe month for transplanting evergreens, and any choice specimens should be left till that time. Of all evergreens, *Rhododendrons* are perhaps the most beautiful; but as it is generally supposed they will not succeed in any other than peat soil, many are deterred from attempting to grow them. The want of peat need be no obstacle to their cultivation, as they will grow in any sharp clean soil that has not been much under cultivation. The best, perhaps, for this purpose, is the trimmings of banks and turf from the side of roads and paths, which contain plenty of sharp grit. The trimmings from the road-side, or any soil that may be used must not contain chalk, or it will be fatal to success. If choice plants are planted, and peat can be obtained at a moderate cost, it is worth while to give them a start in this material. To do this, a hole should be dug large enough to hold a bushel or so, in which the plant will get a good hold, and be independent of the surrounding soil for a year or two. Failing this, leaf soil, about half decomposed, may be used in the same way. In planting, make choice of moderately moist and partially shaded situations, as *Rhododendrons* will not bear excessive drought, and succeed best if not exposed to the full glare of the sun.—J. S., *Wolverstone Park*.

Indoor Fruit Department.

Vines.—Muscats require 5° more heat from the time they are coming into bloom until they are mature than any other sorts. In Vineries where all the shoots have been once stopped, the temperature may be allowed to rise to 85° before giving a little air at the top. No favourable opportunity should be neglected to admit some fresh air, as growing Vines generally stand very much in need of such at this season. Prompt attention must be given to the thinning of bunches and berries on permanent Vines. Those left should be as much equalised as possible as regards size of bunch and the space between each other. The berries on these require to be thinned out more than those in pots, but what number to take out and what to leave must be left to one's own judgment, as all berries do not swell alike, nor will all Vines carry an equal crop. Never allow any pinchings to remain about the house after they are taken off, nor permit the berries to mingle with the soil when thinning. When all have been thinned, the inside border must be supplied with a copious watering. If this can be had at the temperature of the house so much the better. A dusting of guano may with advantage be put all over the surface of the border before watering, and will be washed down about the roots with advantage. Do not rake the surface of the border fine, or the roots may starve for want of water by-and-bye. When *Verbenas* or any other plants that are liable to be infested by red spider are placed in Vineries, a vigilant eye must be kept on them. If syringing be discontinued when the bunches are in bloom, it should

be resumed immediately after the fruit has fairly set. No time should be lost in pruning late Vines, and cleaning the rods and house with as much care as has been exercised in former ones. After this has been accomplished, admit all the air possible, so that the Vines may have that rest before being started again, which the constant firing has hitherto prevented them from enjoying. Any odd bunches of fruit still hanging should not be allowed to interfere with these proceedings, but be cut and stored in the fruit-room.

Pines.—If the soil which it is intended to use for potting these at their spring shift has been outside all winter, protection from wet should be given it forthwith; the corner of the potting-shed is a very suitable cover, and convenient. As time permits, the soil may be prepared for potting. Do not cut the turfs with a spade, or other implement; but tear it asunder with the hands into bits about the size of hens' eggs. This always keeps the fibre entire, which is of much importance with the Pine, especially if the soil is excessively light and sandy. Any of the early Queen pots, which were eased to let the violent bottom-heat escape, should have the plunging material firmly re-pressed around them, so soon as the fruit is up. A uniform temperature at the top and bottom must be constantly supplied to these when the fruit is in a tender state, as it is at this stage that any change or sudden check is more acutely felt than later, when any fluctuation has not so much influence on the future development of the fruit. Other Queens, intended to supply later fruit, should remain in a low temperature; and the drier they can be kept consistently with health, the more certainly will they show fruit when desired.—J. MUIR.

Hardy Fruit.

Orchard trees seldom receive a tithe of the attention they deserve. If, at this season, when pruning, dressing, nailing, &c., is being carried on amongst other kinds of fruit, the orchard trees came in for the same liberal treatment, the results would assuredly be great. Unfortunately, however, it is customary to leave orchards to themselves, and to break through an old-established custom, of however absurd a nature it may be, is invariably a matter of some difficulty. In pruning neglected orchard trees, the endeavour should be made to have every branch clear of its neighbour, and so thinned that, when windy, they do not chafe together. The long and ugly spurs should be shortened back by cutting a few off each year, and in this manner gradually getting rid of all. Lichen and Moss must be cleared off, and, if necessary for its thorough destruction, the stems and branches painted with a mixture of quick-lime and soot. A good dressing of either fresh soil or dung should afterwards be given; and, if digging amongst the trees is impracticable, leave it as a mulching over the roots. If it has not been already done, Raspberries should, at the earliest opportunity, be thinned out; all the old fruiting-canes of last year should be cut away, and the new canes regulated according to the different modes of training; that which is the least laborious and most effective is to have a couple of straining-posts, from five to six feet in height, and well secured in the ground; to these attach three or four strong wires, equidistant, and tie the canes to them; each cane should be distant from the other at least nine inches, and may be shortened back to the same height as the top wire of the fence. It is generally thought that Raspberries are better without manure or other dressing; but this is erroneous, as no other kind of fruit rewards the cultivator more for liberal treatment than the Raspberry. Gooseberry and Currant bushes may be pruned, and the branches of each well thinned out. All kinds are best pruned on the spur principle, with the exception of Black Currants, and these bear the best and the finest fruit on the wood of the previous year, and should be treated accordingly. Birds, and particularly Bullfinches, have now begun their annual work of destroying buds. The best method of reducing them is the gun, and, though by some people its use for such a purpose may be thought cruel, one has to choose, in this part of the country, between this remedy and an absence of fruit. Great diversity of opinion exists as to the best time for pruning Apricots and Peaches. My own opinion is that the moment the buds begin to swell no time should be lost in getting it finished, and the trees nailed and tied to the walls, or trellis, as the case may be. The recent mild weather has brought up the buds of all kinds of fruit, more especially Apricots, and these should therefore have the first attention. Planting all kinds of hardy fruit, when the ground is in suitable condition, should be pushed forward, as it is desirable that such work should be completed early. The same remarks apply to trees growing too freely, which require root-pruning to induce greater fruitfulness.—W. WILDSMITH, *Heckfield*.

Kitchen Garden.

Brussels Sprouts require a considerable time for attaining their full development; and, where an autumn supply is required, if the first sowing was not made last October (which, in many situations, is

a good plan), a box or two should now be sown under glass. As a rule, this vegetable is both sown and planted too late in many places to obtain the most profitable results. Plant out from the seed or nursery bed autumn-sown Cabbages to succeed those planted last September. Stir the soil with a fork between the rows of early Cabbages, selecting a drying day for the operation, and afterwards earth them up. Make a small sowing of Celery, in pans or boxes in heat, for flavouring purposes. Turner's Incomparable White is the best variety for this purpose. When the weather is suitable, and the ground in good working condition, a portion at least of the autumn-sown Onions should be transplanted. In gardens where the Onion maggot is troublesome, it is better to sow the main crop in autumn, somewhat thickly, in a sheltered position, and transplant early in February, or, at least, as soon as the land can be got into a good condition. Select a piece of land that was manured and deeply dug in the autumn or early winter; wheel on a good dressing of charcoal dust, such as can usually be had from the bottoms of heaps where charcoal has been burnt; or, failing this, fall back on the heap of charred refuse reserved when the rubbish-yard was overhauled, spread it evenly over the surface, and rake it well in, or fork it in lightly. Soot also may at all times be beneficially applied. Make the ground tolerably firm, either by treading or drawing the roller over it, and put in the plants, not too deeply, 1 foot row from row, and 4 inches apart in the rows, and a good crop of Onions will be the result. The sooner this is done, if the weather and the ground are suitable, the better, as the plants will be making headway; and, if the maggot should make its appearance, they will not do so much harm as when the Onions are small. If not already done, make a sowing of Veitch's Autumn Cauliflower in pans in heat. This is one of the best for summer use, as it is more capable of withstanding drought than others. Take up the remainder of the crops of Jerusalem Artichokes; select the best for use; place them in a cool cellar or shed, with a little dry sand strewed over them to keep them from shrivelling. In the forcing department every available frame or light will now, or shortly, be brought into requisition, as well as many other contrivances of a makeshift character suggested by the ingenuity of persevering cultivators, and much forethought and attention will be required. In fine mild weather, give as much air as can be done with safety to Potatoes, Carrots, Radishes, Lettuces, &c. Earth up early Potatoes that may require it with light rich soil that has lain in a warm shed a few days to warm. Potatoes with their tops near the glass must be well covered up at night to prevent the frost injuring them. When the early Radishes have all been drawn from amongst the first crops of early Horn Carrots, thin out the latter to about an inch apart, and, in order to fill up all holes, and level displaced soil, sift a little fine rich soil all over the bed, and then water with tepid water (using a rosed pot) all over the bed to settle the young Carrots in their position and hasten their growth. It is at all times necessary to see that all tools are kept in a proper state of repair, and for each man to have one of each kind, such as fork, rake, spade, hoe, &c., for his own individual use, and each man should have also his own place in the tool house, with the necessary hooks or pegs to hang them up, so as to be always ready for use without wasting time in looking for anything he may require.—E. HOBDAV.

COCOA-NUT FIBRE AND ITS USES.

THIS valuable refuse is capable of being used in many ways in garden operations. It is excellent when mixed with sand for propagating. For this purpose I prefer it to leaf mould, the value of which for root-production is, of course, well established. Sand alone is often used for propagating; plants root freely in it, but the roots become too long and tender to do well when they are removed into stiffer soil. When the roots are partially developed in any fibrous substance such a change is never felt, as they are confined to a round portable ball at the base. I have rooted many thousand cuttings in the Cocoa-nut fibre and sand, and I am convinced they took hold of it quicker and with more freedom than any thing I have tried. This applies to having pots filled with it, and also to propagating beds, where a thin layer of it was laid on the top of the flags about the hot-water pipes, and then well watered. On the cuttings being put in, they rooted with wonderful rapidity. Being so open, the heat works freely into and between it, and never becomes sour. As one batch is lifted out it requires to be smoothed over with the hand, and that is all that is necessary before putting in another quantity. One bed of it will root successive batches of cuttings for a whole year without renewal. As a plunging material for propagating or for plants which need bottom-heat, it is equally useful, and it is much longer in decaying than tan or leaves, and is, moreover, cleaner to work in and more pleasant to look at. As a mulching for trees, it is safer and more desirable than tan, or, indeed, than many

kinds of manure, and brings with it none of the Fungi which invariably accompany the use of tan for this purpose. I have seen loam poisoned for plant growing by having tan in a decayed state laid upon its surface. When Hyacinths, Tulips, Narcissus, and other bulbs are potted, they start into growth much more freely under a covering of Cocoa-nut fibre than of ashes or any other matter generally used for that purpose. Bulbs in outside borders show an equal appreciation of it, and it may be used with advantage in mixtures prepared for potting. Soft-wooded stove plants, such as Alocasias, Anthuriums, Marantas, Caladiums, Begonias, Dieffenbachias, &c., succeed well in it. Indeed, it should everywhere take high rank among the requirements for root development, for it can be procured for a mere fraction from nurserymen, or direct from Cocoa-nut mat factories.

J. MUIR

THE KITCHEN GARDEN.

RHUBARB IN LONDON MARKET GARDENS.

OF late years this has become a much sought-for and important vegetable, but half a century ago it was scarcely known in the London market. The late Mr. Myatt, of Deptford, is looked upon as being the father of Rhubarb growers; but his son, the present Mr. Myatt, informs me that Rhubarb was grown in the neighbourhood some years before his father took to growing it, although he was certainly the first who grew it in quantity. The Deptford and neighbouring market gardeners at first thought that Myatt was mad upon the subject; but they soon found out that this was a paying job, though a mad one, and consequently they took to growing it, as also did the majority of the London market gardeners. Now, however, it is almost universally grown, and it is a very accomodating crop, requiring but little care or attention. The varieties grown consist chiefly of the Early Albert, Myatt's Linnæus, Myatt's Victoria, Red Champagne, and Johnson's St. Martin. The last-named sort Mr. Steel has just taken to grow, and it promises well. Mr. Myatt informs me that Red Champagne is much sought after in the market on account of its fine red stalks, and, when forced, its colour is brighter and more imposing than that of other sorts. The soil used for growing Rhubarb is a deep, rich, and moderately moist one, and the position is sometimes in exposed places, and at other times under the shade of fruit trees. The exposed positions are decidedly productive of the finest Rhubarb, hence it may be most desirable to adopt such; but under fruit trees this crop grows almost as well as anything else that could be planted; therefore in order to economise this space, I think few crops pay better than this one. In the Rhubarb season, which is spring, that under the fruit trees grows well, and, as the trees are leafless, they do not shade them much. In sheltered corners, such as are to be found under fruit trees, the produce comes naturally for use about a week sooner than from the open field. In making new plantations, divisions of the old stools are used, and they are planted in rows $2\frac{1}{2}$ feet or 3 feet apart, and from 2 feet to $2\frac{1}{2}$ feet asunder in the rows. No leaves are cut away from them the first year, but the space between the lines is planted with Lettuces or Coleworts. During the second season many stalks are not cut; but in the third year a fair crop is realised. As soon as time can be spared in winter, and before the leaves begin to grow, the ground between the rows is dug over roughly, and a large forkful of rank litter placed over each crown. It would be difficult to take the litter into the plantation on a wheelbarrow, owing to the softness of the newly-dug soil; therefore the workmen carry it in baskets, either on their heads, or, if the baskets are large, in the hand, two people being employed to each of the latter. As a rule, however, some people are employed to fill the round vegetable baskets used; others to carry them on their heads, and a few more to empty their contents over the crowns of the plants. Under the litter the stalks come up clean, tender, and crisp—very much more so than if none were used. The leaf-stalks are pulled for market as long as there is a demand for them, and even in late summer large waggon-loads are often disposed of to jam manufacturers. In bunching the Rhubarb for market, a piece of board, padded with a piece of an old bag, is nailed to the bench in the packing shed, and into it four nails or pegs are driven, two withies being laid crossways for tying. The finest leaves are placed in the bottom, the top and ends being alternate, and over them some small ones, making up the outside again with large stalks, so that the small ones are entirely hidden. Rhubarb-forcing is very simple, and is done in hotbeds covered with hoops and mats. In making young plantations, the sets are sometimes planted about 18 inches apart each way; and, at forcing-time, every other row, and the alternate plants in the row left, are lifted for forcing; old plantations, too, are cleared entirely for forcing. The leaves will be decayed enough to be raked off by the middle of

October, by which time the first portion is usually lifted for forcing. For this purpose trenches are cast out, about 4 feet wide and 2 feet deep, and filled with fermenting manure. Over this a thin layer of common soil is placed, and in it the crowns, after being trimmed of some of their rougher roots, are planted. Over the crowns some loose litter is strewed, and then the beds are hooped over and covered with mats, over which another layer of straw or litter is placed during winter. In the outside covering apertures are made at gathering time, and closed again when done. In February, if the weather be mild, the hoops and mats are commonly dispensed with. In the gardens of Mr. Bessent at Mortlake I have seen some excellent Rhubarb produced in pits, like deep Potato pits, with some heating material underneath, and some loose straw merely shaken loosely over them. D.

Endive.—This vegetable is grown to perfection in the London market gardens, and is ready for use from the middle of August till Christmas. Many growers keep up a supply during the winter and early spring by lifting the plants for winter use and planting them in a frame or amongst sand in a shed, and for spring use from late sowings planted out in dry and sheltered soil. As our markets, however, are so liberally and easily furnished with beautiful Endives from France during the winter, it would not pay the English grower to cultivate them for winter and early spring market. The green curled and the dwarf variety of the same are two sorts commonly grown; but a few of the broad-leaved kinds are sometimes grown in gardens. In the middle of May a sowing is made either in a cold frame or a bed of light soil in the open air, and covered with litter like Radishes. This early crop is commonly planted out on the Celery ridges about the middle or end of June, and becomes fit for use in August. Very early Endives are liable to "run" before they fill up; therefore, earlier sowings than that of May are not to be relied on, and much dependence cannot even be placed on that. A large sowing is made in the open air in June, and another smaller one in July. The plants in the seed bed are thinned out a little at an early stage if thick, and are transplanted permanently in rows about 15 inches apart, and a foot asunder in the rows, between Celery or between summer Cauliflowers, Lettuces, or Cabbages, or in an open field by themselves. Beyond hoeing, no further care is bestowed on them until they have grown enough for tying up, when their leaves are gathered up together and tied round their middle with withies or pieces of matting, like Lettuces. They are kept tied up for a fortnight or three weeks in order that they may be well blanched for market. In September and October the Endives are very fine and abundant in our markets. Mr. Poupart, Mortlake; Messrs. Evans, Dancer, Humphreys, and others, Fulham Fields, are amongst our largest Endive growers.—F.

Exporting the Colorado Potato Beetle.—I notice that the Governments of Switzerland, Austria, and Belgium have adopted stringent measures against the importation of American Potatoes infected with the Colorado Potato beetle. Now, if the wise men of Europe can tell us what they mean by the word "infected," as applied in this instance, I, for one, desire to have them give an explanation. Their entomologists, at least, should know that the beetle referred to does not infect, or in any manner attack, the tuber, but confines itself to the leaves in summer; and the chances of exporting this beetle with the Potatoes is about as likely to occur as sending a cotton planter's "Sambo" with a bale of cotton. Then, again, does not everybody know that this beetle is a native of Texas as well as of the plains to the northward, from whence cotton, buffalo hides, and various other articles have been shipped direct to Europe for the past century, all without once infecting the Potatoes of the Old World? But, for all this, the Colorado Potato pest may be carried to Europe, and become naturalised there; still, it is far more likely to be transported in some other material than among Potatoes, because it is not so stupid as to go to roost for the winter upon a Potato when it can find more comfortable quarters. If the European Governments desire to prevent the introduction and spread of this beetle, let them send over for a bushel preserved in alcohol, and have these mounted and distributed among the farmers, in order that they shall be known and recognised at the moment of their first appearance. Knowledge is power in these matters as well as others, and, had our farmers known the pest on its advent, and cared to destroy it, we should never have heard of Colorado Potato beetles east of the Mississippi River. When these beetles become abundant about our Atlantic seaports, they will no doubt be carried aboard of outgoing vessels, with fresh vegetables from gardens, or even upon the clothes or baggage of passengers; and it would be well for our transatlantic cousins to know them on arrival, in order to bestow a fitting reception. But this beetle neither infects by laying its eggs upon, or in the tubers; neither is it in the habit of crawling into barrels of

Potatoes for the purpose of obtaining a free ride by rail or water; consequently, the excluding of Potatoes from a country as a precautionary measure, as intended in this instance, shows ignorance on the part of the makers of such regulations.—Correspondent, "Moore's Rural."

Kitchen Garden Edgings.—Stevens' garden edging brick, which we recently saw in use in the kitchen garden at Trentham, is by far the best and neatest of any we have met with. Mr. Stevens is doing away with live edgings, such as Box and Ivy, which have been formerly used, and after two years' experience is preparing to replace them by this brick, a light stone-coloured brick of his own design, remarkable for its neatness and durability. Its form admits of its being laid so firmly as to be practically immovable; its colour gives it the appearance of stone edging; and its outline is so simple and neat as to be thoroughly unobtrusive, though perfectly efficient. With an edging of this sort the walks can be kept clean with the least possible trouble by adopting the system of dressing them with salt, which is always a risky experiment when live edgings are made use of. This edging brick is 18 inches long, 5 inches high, and 5 inches wide at the sole, $2\frac{1}{2}$ inches being set above ground. Its great merit is the combination of elegance with durability and efficiency which it presents. This durability, of course, is due to the particular material of which it is made.—"Florist."

Royal Horticultural Society.—The present Council came into office in the belief that their predecessors had exaggerated the difficulties of the society, and that they were sacrificing the Society's interest in arranging with Her Majesty's Commissioners, in consideration of relief from rent and debenture interest (estimated to amount in all to about £5,400 a year), to admit exhibition visitors free. They then adopted the opposite theory, that the difficulties of the Society had not been fully shown to them. My object now, however, is to urge a change which I believe would conciliate country horticulturists, and make them join and support the Society, and one that would not injure the recreation ground of the resident Fellows. This is, to let the resident fellows and those wanting the use of the gardens pay their present subscriptions, and admit country and other Fellow horticulturists to Chiswick at all times, but at South Kensington to shows and meetings only, charging them a guinea subscription. I believe that if this plan were properly worked by country committees, thousands of new Fellows would join, and then the Society would be a national one. Unless some means are taken for bringing about this result, immensely valuable land, bought with the peoples' money, cannot long be allowed by those who are responsible for its use for public objects to continue of the very small public utility the South Kensington Gardens now are.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath.*

THE LATE MR. BUCKLEY.

In your last week's "Obituary" you briefly alluded to the death of our old friend, Mr. Buckley, who, during a period of thirty-three years, was in the employ of Messrs. Rollisson & Sons, for the greater part of which time he held the responsible position of manager at their Tooting nurseries. So intimately was he connected with the botanical reputation of that establishment, that I think a more lengthened notice than that which appeared at p. 82 will be acceptable to many of your readers, not a few of whom must have been personally acquainted with the subject of your remarks. He was born and served his apprenticeship in Lancashire, whence he removed to Woburn, where, under Mr. Forbes, and surrounded by the botanical associations of that fine old place—then noted for its collections of Willows and Grasses—he found full scope for the development of his abilities. Having resided there for some four or five years, during the latter portion of which he acted in the capacity of foreman, he removed to the Tooting Nurseries, where he remained in active employment till seized by paralysis, about twelve months ago. Singularly enough, this seizure was almost simultaneous with that of his friend Mr. Gibson, whom he only survived a few weeks. Endowed with a wonderfully retentive memory and great powers of close observation, and having a thorough love for his profession, he was long admitted to be one of the most accomplished plantmen in the trade. He was invariably willing to impart his knowledge to others, as everyone who has had the pleasure of a walk round the nurseries under his guidance will be ready to admit. Unobtrusive and reticent to a degree on every other point, the mention of any botanical novelty at once touched a sympathetic chord, and the wealth of a well-stored mind was soon revealed. Further, he was a pretty frequent contributor to some of the horticultural periodicals. Mr. Buckley did not marry until late in life, and we regret to say that, owing to his protracted illness, he leaves a widow and three young children almost wholly unprovided for. I sincerely trust, therefore, that some of his London friends may be induced to act on their behalf, and commence a subscription, to which I, for one, shall be most happy to contribute.

Botanic Gardens, Hull.

J. C. NIVEN.

NOTES AND QUESTIONS.

[THE following notes and questions came to hand, or were answered too late for insertion in their several departments.]

Hardiness of *Dracæna indivisa*.—This has withstood uninjured the somewhat severe frost which we lately experienced in the County Wicklow.—T. P. T.

Scotch Fir Seeds.—Will some of your correspondents kindly give me a hint as to the best time for sowing these, and how they ought to be treated?—Hortus.

Wintering *Echeveria secunda glauca*.—Where space indoors is limited for the accommodation of plants of this succulent during winter, they can be wintered equally safe by planting them out on a sloping bank formed under a south wall. A little dry hay shaken over them will afford them ample protection.—T. P. T., *Wicklow.*

A Very Dwarf Mulberry.—The "Revue Horticole" describes a seedling Mulberry, raised by a M. Brun, which is remarkable for an extremely dwarf tufted habit. In three years the stem has not attained more than about 18 inches, while other seedlings of the same batch have in a like period attained a height of 9 or 10 feet.

Williams's Early Prolific Dwarf French Bean.—This is about a week earlier than Sir Joseph Paxton and the Dark Dun, grown under the same circumstances. Last season I used Williams's Bean for my two earliest sowings out of doors, and in each case it was a week in advance of all others.—R. M., *Cheadle.*

Red-skinned Flour-ball Potato.—This is, undoubtedly, the best late Potato in cultivation. It has produced with us this last season a sack of 150 lbs., or 3 bushels, to the square perch, and scarcely a bad one could be found among them. It must be borne in mind that it is a very late variety, and should not be used until the very last, when it will be found to be quite dry and of excellent flavour.—THOS. P. TURNER, *Killruddery, Bray, Wicklow.*

Twisting Pot Vines.—We grow here about a dozen pot Vines for table decoration. The trellis, a simple one, has four upright wires, and is surrounded at the top with a hoop. The Vines are tied round this; and, when they are started, I find the twist to be beneficial rather than otherwise, as every bud starts; whilst others, simply laid down, have not broken so regularly; thus showing that Vines can hardly be twisted too much.—R. GILBERT.

All the Year Round Lettuce.—This is a valuable winter Lettuce. Last January I saw two beds of it in excellent condition. These were about 4 feet wide and perhaps 20 yards long. A wider alley than usual ran between them, and they were raised higher than is usually the case. This, and the soil being a good deal mixed with ashes, gave the plants a naturally dry bed, and one unfavourable to the attacks of slugs.—M.

Geraniums for Indoor Winter Decoration.—Whatever may be said against "hideous miles of scarlet Geraniums," it must at least be granted that the scarlet Geranium fills a gap in the greenhouse at seasons of the year when few other decorative plants are in bloom. I hear from eye witnesses that Mr. Pearson's Geraniums have been a perfect sheet of bloom all through December. My seedlings were very lovely till an accident took place with the boiler, and the frost got into my little greenhouse. There are still some fine blooms out, and, as an artist, I may say that no flower has such a range of exquisite tones of colour as our Zonal Geranium.—F. M.

The Soap Plant (*Chlorogalum pomeridianum*).—This plant, though somewhat rare, can scarcely claim to be classed among the novelties of the current year. It is now six or more years since I saw it growing in the County Cork at Rhin Rhonan, the residence of J. P. Ronayne, Esq., M.P., where it had been established for a considerable time, and was growing freely on a piece of rock-work. When travelling in California some years previously Mr. Ronayne collected and, on his return, carried home with him several bulbs of this plant. I may add that the collection of rock and Alpine plants brought together at Rhin Rhonan is one of the most varied and interesting with which I am acquainted. In the Botanic Gardens here the *Chlorogalum* has been growing for some years, and in one of them, the College Botanic Garden, I had more than once the pleasure of seeing it in flower, so that in these parts, at all events, it is no novelty.—A. B., *Dublin.*

Hotbeds.—I have seen a good many of these; but never one to which it was easy to apply fresh fermenting material without disturbing the plant bed. Is there any easy way of getting the warm manure under the bed?—C. RICHARDSON. [Mr. Groom, Henham Hall, recommends hollow-bottomed beds, which, he says, are in every way superior to such as are solid. The plan which he adopts is to build up corner piers of brick to the required height, say about 18 inches in front and 24 inches at the back, and to lay strong bearers lengthways on these piers, and stout planks crosswise on the bearers to form a floor, leaving sufficient apertures for the heat to pass through. He then sets the frame on and puts into it about 3 inches of leaf mould to keep down the steam; a load of strong fresh dung is now put under the frame, and enclosed with a lining of any sort of litter or garden refuse that may be at hand. In this way the heat is up and the bed fit for planting in less than a week, thus effecting a great saving of time; and the heat may be regulated to a degree. Frames set up in this way are useful all the year round for forcing Asparagus, early Potatoes, propagating bedding plants, for Cucumbers and Melons, and for growing young stock of stove plants during the summer.]

The Large-flowered *Hepatica angulosa* Best.—Let me caution your correspondent Mr. Miles (see p. 82), who intends growing *Hepatica angulosa* in a pot, to be careful to get the large-flowered variety, for there are two. Some years ago, after Messrs. Backhouse had shown their splendid potful of *Hepatica angulosa* at South Kensington, I grew it, and, though hearing of flowers the size of a crown piece, could never produce them much larger than those of the old single blue, though my plants had the true *angulosa* leaves. At last I got some new plants, which, without any trouble, at once yielded very large flowers, and we have since had the two varieties blooming side by side. *Hepaticas* in our bed sow themselves, though we sometimes grow the seed in pans; most of them are single pink flowers, but some of the seedlings are of a deeper and brighter pink than the old single Pink. With us, spring flowers are just coming into beauty; the Christmas Rose and hardy Cyclamens of many colours came first; then *Jasminum nudiflorum*; then the Winter Aconite, then *Crocus Imperati*, and the first of the *Hepaticas*. Mr. Dean's beautiful *Primula auriculiflora* was one of the first of our Primroses; *Lonicera fragrantissima* is just coming into bloom, and *Chimonanthus fragrans*, and *Scilla sibirica*, have only, as yet, produced one or two blooms.—GEORGE WILSON, *Heatherbank, Weybridge.*

New Varieties of Potatoes.—First-class Certificates have lately been awarded by the Royal Horticultural Society to Snowflake and Alpha, the two newest Potatoes sent to England from the United States by Messrs. Bliss.

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

DO VARIETIES WEAR OUT?

DR. ASA GRAY has discussed this question with his usual ability. The point, be it noted, is not whether varieties change and break into other varieties that may possess additional vigour of constitution, and supersede existing varieties in the past or present, but whether they die of weakness or old age, and that without modification of form, size, colour, and constitution. Nor must we consider varieties exhibiting abnormal development of any particular part that may weaken them, notably such, for instance, as Wheat with ears of extraordinary length or weight; Mangolds with a preponderating size of root compared with the short tufts of scanty leaves—the types most sought after by cultivators; or Cauliflowers all heads, with little more than leaf enough to bend over and blanch those heads into greater tenderness and spotless whiteness—the form that delights the eyes of horticulturists; but whether varieties with perfectly well-developed constitutions, and all their parts so proportioned as to maintain a normal and healthy vitality, do in fact die out of old age. There are numberless forces tending to drive out the old and to bring in the new; consequently, many of the old varieties are constantly passing away. Take, for instance, garden Peas. Owing to the excitement caused by the present demand for new Peas, and by the many irreproachable kinds now catalogued, many of the old favourites are disappearing altogether or reappearing under new names. Either way the identity of the variety is lost. But will any one affirm that Knight's Dwarf or tall Marrow, or British Queen, or Scimitar, showed any signs of disease, or were touched with the weakness or imbecility of old age? No; these varieties are as good and as vigorous as ever; and such is the case with hundreds of other vegetables, plants, and flowers. Even the Golden Pippin Apple, which seemed at one time to have been given up as hopeless, has never been shown or grown in higher perfection than in the year 1874. It has no sign of decrepitude in leaf, branch, or fruit; and the same holds good of Nonpareils, Ribston Pippins, and other fruits handed down to us from ancient times. Indeed, we find, on looking carefully into the notion that varieties die a natural death, that the idea has been based on a fallacy, thus—individuals die, therefore so also must varieties. On asking for proof, the assumed fact is thus met; with the death of the individual the progeny of that individual perish also; or, in other words, when the parent dies, the children also die. Grant this, and the death of the individual is, as a matter of course, the death of the variety; but one can but marvel that an intellect, like that of the late Mr. Andrew Knight, could ever have found room for such a crotchet—the mere baseless fabric, not of a theory, but of a dream. And yet that he held this view is clear. Dr. Asa Gray quotes the fact from the "Philosophical Transaction" of 1810, in which Mr. Knight propounded the theory, not merely of a natural limit to varieties from grafts and cuttings, but even that they would not survive the natural term of the seedling tree from which they were originally taken. With such views it is no wonder that he proclaimed the sure and speedy decadence of varieties. It could not be otherwise, if his premises were true. The marvel is, that he or anyone could have promulgated a statement so opposed to all history and experience of vegetation. And yet we find Mr. Sisley, who seems to have caught the falling mantle of Mr. Knight in this matter, maintaining that varieties are subject to the same laws of life and death as individuals, inasmuch as they are individuals. If individuals, they are of such a type as to be endowed with the property of life and vigour in continuity. Doubtless individual plants die, though whether really from old age or not is doubtful. The majority of them perish of starvation. The soil is so thoroughly drained of food, their larder swept so clean by the spongioles or feeding points of the roots, that nothing is left to support the plant. Were it otherwise,

I think Dr. Lindley somewhere ventured the opinion that there was no reason, in the nature of the life or constitution of a tree, why it should not live for ever. Trees do live for many centuries, and some writers have expressed a belief that some of the Wellingtonias of California may have waved their proud heads over the far-reaching waters of the deluge. To admit the death of individual plants is one thing; but to base upon this fact the argument that other plants, raised from scions or cuttings of the same plant, die with it, is quite another and a different one. If, as it appears, the theory of the wearing out of varieties is based upon the death of individuals, it must, as a matter of course, be given up. The death of individuals runs parallel with the continuity of varieties, and, in fact, is an element in their stability and perpetuity. Dr. Asa Gray, while contesting the theory of the wearing out of varieties, draws a wide distinction between the stability of those raised from seeds and those propagated by buds, using the term in its widest sense as indicative of all means of increase other than by seed. Fortunately, too, he advances reasons for his conclusions—these are, that cross-fertilisation between the individuals of a species is Nature's mode of increase; that self-fertilised species degenerate; and, that old age brings on debility. Admitting the first, it is not obvious how cross-fertilisation can be a security of stability; for the different varieties of a species are thus apt to be intermingled, and change of type or form is the result of the cross. And, as far as we are aware, Nature has made no provision, physiological or otherwise, to ensure cross-breeding only between different plants of the same variety. As to old age, this argument could only have been started on the assumption that a variety is an individual, and subject to its laws and conditions of weakness, decay, and death—an assumption that Dr. Asa Gray has just disposed of, by showing that individuals, by division, gain an increase, not a loss, of life or vital force. In a word, plants raised from buds are, to all intents and purposes, new plants, characterised by all the energy and force of life that are inherent in those raised from seeds. Further, it is by no means proved that self-fertilised species or varieties degenerate. Analogous instances in the animal kingdom even are not conclusive. Where purity of strain is an object this has been the most frequent mode of perpetuating it; and it is by no means certain that the vigour and longevity of plants have been reduced in consequence. Even if it were so, another statement of Dr. Asa Gray's has assuredly not been proven, viz., that bud propagation is the closest possible kind of close breeding. This, which goes to the root of the matter, is by no means obvious. Propagation by buds is not breeding at all, in the ordinary sense of the word; it is multiplication. Each bud is a plant, as it were, in embryo; detach it from the parent and give it roots, and it is a plant in fact. It has undergone no degeneration, debility, or change of any kind; as it was in the parent, so it is now, with all the powers of the original plant regenerated and intensified by its altered conditions and its closer proximity to the earth. It is conceivable how propagation by seed may either reinforce or lower vital force in plants; but it is not conceivable how bud propagation can be called close breeding, or how similar effects can follow in its train. Dr. Asa Gray quotes Mr. Darwin's brilliant discoveries in proof of his theory that cross-fertilisation—being obviously Nature's favourite mode of increase, is a source of strength as well. The same author's hypothesis of parthenogenesis may be cited to prove that not only each bud of a plant, but each minute gemmule, has the entire potentialities of the plant within it, and may reproduce the whole with an equality of power, circumstances permitting. In the multiplication of varieties from seed, there may be a loss or a gain of vital force; in the multiplication by buds, that force remains constant, provided we propagate from healthy plants. Moreover, the disturbing effects of disease will be more potent in seedling plants than in buds, inasmuch as seedlings are moulded in character and strength by the plant as a whole; whereas buds are local centres of vitality, each with its own individuality, so that one bud may be strong, another weak—one healthy, and another diseased, when placed side by side. Hence, by the careful selection of buds, and the use of those of normal strength and vigour, the variety is perpetuated with such certainty and constancy that not only is there little, but no perceptible change at all, on this score from

"the mills of the gods that grind so exceedingly slow" within the limits of our human experience. Within range of horticultural history, varieties cannot be said to have died out from sheer lack of vital force, weakness, or age. As to changes following in the track of alterations of climatal conditions and geological development, that is another and quite a distinct question that hardly affects the present enquiry. D. T. FISH.

FORCING ROSES.

THOSE who have to lift their plants from open borders after this time of the year, must not expect many flowers, if any; but rather aim at getting a good early growth, that they may have a supply next winter. Had the plants been potted early in November, they might have been forced into flower in April, and would have been in good condition for starting in November following. Select good vigorous plants from the borders, take them up with all the roots possible, prune them down to one or two buds, and pot them in 10-inch or 12-inch pots, cleanly but not too deeply crooked, using a good friable loam and a little sand, and for Teas and tender-growing sorts generally, rich leaf mould may be added. After potting, the plants should be watered and stored in a cold pit or house, where it is only necessary to exclude frost, till about the beginning of March. At this date they may be started in a very gentle temperature of about 45° at night and from 50° to 60°, or 65°, by day, according as the weather is cold, dull, or sunny. The plants must be kept near the glass and well exposed to the light, taking care at the same time to admit air freely at all times, consistently with the proper temperature and the avoidance of draughts; in fact, they may be treated like late Peaches generally. Where the shoots are too thick, or crowded, they may be thinned out; greenfly must be kept down by frequent gentle smokings with tobacco-paper and syringing, and mildew by slight dustings of flowers of sulphur. Water must be liberally supplied to the roots as growth progresses—at no time should they be allowed to get parched; but liquid manure will not be required for plants so recently potted in fresh soil. The strongest shoots may be pinched to equalise the vigour; but, as a rule, pot Roses, grown for flowers and not for exhibition, require little attention other than watering and keeping clean. By the beginning of June they may be turned out of doors and plunged in ashes on a south or west border. Here they will require watering only, and any blooms they make, either before or after this date, should be pinched off. By September, though the points of the shoots may be green, the wood will be ripe enough at the base, and the plants should be pruned to one or two buds; and before frost sets in they must be moved into a cold house until they are wanted. Whether the plants have been bought or prepared at home, the directions for forcing are the same. Like most other plants grown for forcing everything depends on the preparatory treatment above described. Early ripened and early pruned Roses force easily into flower. Force gently, ventilate regularly, keep the plants clean, give them plenty of light, and make the most of sun heat; 45° by night, and from 50° to 55° by day, is a high enough temperature at first, till the buds are about an inch long, when 5° may be added to these figures. When the buds appear, the night temperature may be raised to 60°, and it may go up to 75° with sunheat, and these temperatures should not be exceeded during the winter and early spring months. Later in the season, when the days are longer and finer, and when more air can be given they will stand, and even be benefited by, a much higher temperature; but earlier batches should not be pushed too hard where a healthy growth and good foliage, upon which the next year's success depends, is desired. When the plants have done flowering, and have to be moved to make room for a succession, they must not be forgotten, as they often are, for it must be borne in mind, that on their treatment after this date the next year's supply of Roses depends. From this time they must be treated to an airy summer temperature, and carefully watered—occasionally with weak liquid manure—till about the beginning of summer, when they may be set out of doors and plunged in ashes as before; but this time behind a north wall, as plants forced early are only too disposed to come away before their time, and the object is to keep them back. The bottom buds will, however, not break till they are pruned, which should be delayed till September, and afterwards they may be treated as in the year previous, only that before forcing the surface soil should be removed from the pots and a rich top dressing given, consisting of good loam, well-rotted cowdung, and a little bone dust. When the plants get weak after a few years' forcing, they may be restored to the border again, and their place filled with fresh plants. By following this practice, and always forcing the earliest first, a continual succession of good plants may be kept up.

J. S.

NOTES OF THE WEEK.

— A BEAUTIFUL variety of *Narcissus Tazetta* has become naturalised in many parts of Cornwall, and is just now flowering profusely at St. Michael's Mount and elsewhere in that county. Through the kindness of Mr. Tyerman, who has sent us fresh specimens of it, we find that it is a variety often met with in gardens under the name of *Luna*. The scape bears from six to eight flowers, which are of snowy whiteness, with delicate pale lemon-coloured cups. If any of our readers who may be staying at Mentone or Nice would favour us with specimens of *Narcissi*, which will now be blooming freely at both places, we shall be greatly obliged.

— TREE FERNS are nearly all of elegant and pleasing habit, and one deserving these epithets in a high degree is *Cyathea insignis*, a native of Jamaica and other West Indian islands. A magnificent specimen of this species recently attracted admiration in the tropical conservatory at Kew. It has fronds upwards of 12 feet in length, the stipes or stalks of which are densely clothed with long glossy scales.

— M. VAN HULLE writes to us to say that some seeds of the *Victoria regia* and *Euryale* were kept in a dry place ready to show to visitors who might be curious to inspect seeds of these aquatic plants. These seeds had remained dry all the summer of 1874; but about a month since one of the workmen threw them into a glass of water, where the *Euryale* germinated, and has gone on since growing satisfactorily. Here, then, is an instance of *Euryale* seed preserving its germinating powers, without water, during an entire season.

— THE laying out of that portion of the Thames Embankment which lies between Outram's statue and Whitehall Gardens is being rapidly proceeded with. Within the last week or two, a large number of beds have been formed and heavily manured; the foundations of many of the paths have been put in, and a very considerable number of trees planted. The portion of land on the west side towards Whitehall, which was reserved by the Crown when the first arrangements with the Metropolitan Board of Works were made, has been partitioned off, and the Crown has undertaken to erect an ornamental wall at the western boundary of the garden, which, it is expected, will be opened in May next.

— MR. TYERMAN, of Penlee, Tregoney, Cornwall, has sent us some twenty or thirty species of outdoor flowers in beautiful condition. Among the most striking are *Narcissus minor* and *N. Tazetta*, two varieties of *Anemone coronaria*, *Iris stylosa*, and the rich purple and yellow *I. reticulata*; *Saxifraga crassifolia*, several kinds of Grape Hyacinths (*Muscari*), *Habrothamnus fasciculatus*, *Veronica Andersoni variegata*, *Cytisus fragrans*, *Triteleia uniflora*, *Grevillea rosmarinifolia*, New Holland Daisy, known in gardens as *Vittadinia trilobata*, and others, now flowering in the open air in that county.

— IN the current number of the "Botanical Magazine" is a coloured figure of *Senecio macroglossus*, a large flowered scandent species, closely resembling the common Wood Ivy in its habit of growth. The flowers, which are eight-rayed, are about 2 inches across, and of a clear yellow. Dr. Hooker states that it is the largest-flowered species of the extensive genus to which it belongs—a genus which contains nearly a thousand species, of which our common Groundsel (*S. vulgaris*) is a well-known example. In point of size, however, we are inclined to think that the beautiful purple-rayed, golden-eyed *S. pulcher* ("Bot. Mag." t. 5, 959), introduced to our gardens by Mr. J. Tyerman, of Penlee, Tregoney, is still larger, and certainly far more showy. *S. macroglossus* is similar in habit to *S. mikanioides* (German Ivy), a plant largely used in Germany, Russia, and America, as a pot plant, and for training around the cornices of apartments.

— A LECTURE on Fungi in relation to disease was delivered on Wednesday evening last by the Rev. M. J. Berkeley, in the council room of the Royal Horticultural Society at South Kensington. The lecturer explained the many theories advanced by medical men and Fungologists in relation to the cholera and other diseases, and pointed out that a national school of scientific research is much to be desired in this country, on the same plan as those in Germany and elsewhere. The reverend lecturer alluded to the fermentation which takes place in flesh wounds, and stated that in many cases this fermentation or decomposition is due to the agency of Fungoid spores, which are so minute as to be borne to any part of the globe by the slightest breeze; hence the use of cotton-wool or other covering to exclude these atoms, and the great care which is now taken by surgeons to disinfect their amputating implements with carbolic acid before performing any operation. In conclusion, Mr. Berkeley alluded to the baneful effects of the Ergot of the common Rye, which, if administered during failing health, has the singular property of causing the human body to become ulcerated in a very alarming manner, and cattle not unfrequently are injured in a similar way by eating Rye Grass affected by this Fungus.

THE FRUIT GARDEN.

MELON CULTURE.

(THE AFRICAN MELON.)

WE adopt the same routine of cultivation both in pits and houses, and all varieties are treated alike, with the exception of the African kind, which is distinguished from all others by the size of its fruit and foliage, and which requires rather more space than any of the others. Our Melon-house, from which we generally get our earliest and latest crops, is heated by means of a flow and return pipe on each side. It is a low, broad, span-roofed structure, in which there is a central bed 6 feet wide, and side beds 3 feet wide, each bed being furnished with a flow and return pipe for bottom heat when required. We only take one crop from each set of plants, as I never could see any advantage in keeping them longer. When preparing for the plants, we fill the beds, nearly level with their tops, with fermenting stable manure packed very firmly, in order that it may give a gentle lasting heat, which is supplemented by that from the hot-water pipes, whenever it falls below 85°. On the fermenting material we place a layer of turf from an old pasture, and on that about a foot in thickness of the same material roughly chopped up. This is rammed down as firmly as mallets and rammers can do it. As soon as the soil is thoroughly warmed, we plant one healthy young plant under

Sir S. Baker's African Melon contrasted with Scarlet Gem.

each rafter, and support it with a stake, until it reaches the trellis, which is about 15 inches from the glass. Under a brisk moist temperature, the plants quickly attain the desired height, when they are stopped, and the side shoots trained out horizontally. They soon afterwards show fruits on every shoot, about a dozen of which are allowed to set, care being taken to secure a somewhat dry atmosphere until they commence to swell, when five or six of the best should be selected and the rest removed. At this stage of their growth we always top dress the beds with loam and a little decayed pigeons' dung. While the crop is swelling we give tepid water in abundance, as, if Melons are once allowed to get dry, they are permanently injured; but as soon as they show signs of ripening, water is withheld and a dry cool atmosphere maintained. Green or white-fleshed kinds are the favourites here, Gilbert's Improved, Victory of Bath, and Green Fleshed being excellent varieties and heavy croppers. I may mention that the African variety produced fruits each weighing from 8 to 18½ lbs., and that the average weight of fruit produced by each plant of other sorts has been 24 lbs., or six fruits of 4 lbs. each. As we only grew the African kind as a curiosity, we limited the number of fruits on each plant to three, so as to see what size they would attain, and they hung on the plant quite a month after they were

fully ripe. The universal opinion of all good judges of Melons is, that this variety might successfully compete, both for size and flavour, with any other in existence—even in this exceptionally favourable season for Melons. JAMES GROOM.

Henham Gardens, Suffolk.

THE QUEEN PINE-APPLE.

IF the St. Michael Pines continue to arrive annually, and in increasing abundance during the autumn, winter, and spring months, it is quite evident that Pine-growing in England during that period may be discontinued, except where it is carried on for the pleasure of the thing, for the St. Michael Pines are much larger and better than the general sample of home-grown winter fruit, and they can be bought cheaper than the latter can be produced, or at least as cheap. Should this happen, our Pine-growing will be confined to the summer supply, and by preference we shall have to fall back upon the Queen, as this is now so well adapted for early forcing, and, as regards appearance and flavour, is undoubtedly one of the very best. Unfortunately the Queen has got a notorious reputation for being a shy fruiter, or, rather, missing to fruit just at the time it is wanted—a character which I am sure it does not deserve, for, according to my uniform experience it is one of the most certain in this respect. Where it behaves otherwise it must be due to the treatment, and is not the plant's fault. The Queen deserves a good character from me at least, for during the last nine years I have grown about thirty fruiterers annually (never more) of that variety for a special purpose in summer, and it has never failed to "show" at the desired time. Sometimes one or two plants miss, but, as a rule, nearly the whole fruit yearly at the same time. I have been a frequent exhibitor of Pines at the summer shows in different parts of the country, and I have always had Pines for the purpose while watching the supply for the table at the same time, and not unfrequently have had as many as from six to nine fruits out at once for exhibition. I merely mention this to show that my limited number of fruiting plants must have come up to time, or I could not have done as much. On several occasions I sold seven or eight of these fruits for 21s. each, after they had been some days exhibited, as they were not wanted at home. This season we started the half of our Queens in December, and not one in the row has missed, whilst the remaining few look as if they would bolt also when wanted. What can be accomplished with a dozen plants can also be done with a hundred. I attribute my success in getting the plants to throw up so surely to firm potting, and getting well-ripened plants by autumn in the first instance, but chiefly to starting them gradually, as regards bottom-heat. I am so confident that a sudden rise in the bottom-heat—say, from 65° or 70° to 90° at once—will cause a miss, that I would undertake to make the best batch of Queens I ever saw, or most of them, miss fruit by such treatment, unless the fruit-buds were almost in sight. Here, our Queens never experience a bottom-heat below 70° and it is only so low for one month. When started, it is raised very gradually to 75°, and this is never exceeded till the fruit is fairly up, when it is slowly pushed on to 82°, and this figure is never exceeded by fire-heat. It will be perceived that, in this practice, I am simply following the usual rule laid down with regard to Vines and other fruit. No one would think of starting Vines at a summer temperature at first. With Peaches such treatment would be considered madness, with forced Strawberries it would be ruin; and the same may be said of other plants. Why, therefore, Pines should be made an exception I cannot see; but it is so, for a jump of 20° of both top and bottom-heat at starting time is the general practice. Only lately I saw it recommended to start, at a bottom-heat of 90°, and a maximum top-heat of 85°, Queens that had been at rest the week before at a temperature 20° or more below these figures. The writer had much to say about Queens missing, and no wonder. Nature affords no parallel for such treatment, and both practice and theory prove it to be wrong. The theory practically inculcated by all good Pine growers is that the embryo fruit bud is perfected with the close of the summer's growth before the plant goes to rest, and that when the plants

are started the fruit shows itself with the first indications of growth. This, I apprehend, is the meaning of the oft-repeated advice, "get the plants well matured by autumn, and choose the best-ripened and thickest-necked plants for fruiting." If the fruit is not there we cannot get it there until growth is again checked by severe and unnatural means, to which gardeners never resort if they can help it. Now, assuming this theory to be correct, viz., that the embryo fruit bud is matured in autumn, what treatment is most likely to promote its healthy development when the plants are started—a sudden acceleration of temperature or the reverse? According to physiologists it requires a higher temperature to bring plants into leaf than into flower, and when they are hurried in the earlier stages of growth it is at the expense of the crop of fruit. This all gardeners know to be the truth in the case of fruit trees, as in the Peach and Strawberry already mentioned, and that the same law holds good with the Pine there can hardly be the least doubt. If it requires as high a temperature to start it as it does to swell its fruit, it is an exception to all other plants; but that it is not so I am satisfied from the experience above recorded. Some years ago I was in a garden where some hundreds of fruiting Pines were grown, and the gardener complained grievously of the number of "misses." Quite two-thirds of his plants had missed, and he believed in a "smart bottom-heat to begin with." His Queens, both the first and second lot, had been started some three or four months, and looked as if their fruiting would continue to be a matter of expectation for ever. It is a serious misfortune to a gardener when a batch of Pines is lost in this manner, and any explanation that can be thrown upon the subject will, no doubt, be welcome.

J. S. W.

SHANKING OF GRAPES.

THIS disease is very general amongst Grapes. It is the very worst of all the affections to which Vines are liable. If attacked with any kind of insect, even by the Phylloxera, mildew, or any other pest, the fruit can usually be made use of in some form or other, but when the disease is shanking it is utterly worthless. Some think their Grapes are shanked when they are not; others, who would fain escape the fell destroyer, think shanking has not set in when it has. I have often met with amateur Grape growers who could not understand how many of their Grape berries, when apparently ripe, were found to be quite sour; these were shanked. Shankd fruit is easily known; but that the disease may be the more readily detected, I will briefly describe the unmistakeable indications of it. The stalk of the berry first becomes yellow, then brown, and lastly quite black and wiry. This is seldom confined to a single berry—it begins at the point of the bunch which it ascends. Sometimes only a shoulder is affected, and in that case it can be cut away, leaving the remainder sound, but in general it affects the whole bunch; after the stalks blacken, the berries shrivel to a greater or less extent, when they undergo a fermenting process which makes them sour and more unpalatable than when quite green. It rarely shows itself until after the berries are stoned and have started to swell a second time; but after that it may appear at any moment, even when the fruit has hung for a long time quite ripe. The first crop on young Vines sometimes shanks, but the evil is more generally confined to old ones which have been planted out for many years. The future well-being of young Vines is very doubtful when shanking appears among their fruit, as, if once attacked, the disease usually returns afterwards, unless curative measures are at once taken. I have often observed that early and quickly-ripened Grapes do not shank so much as late ones that hang long before arriving at maturity. I have indeed rarely seen a shanked berry in Grapes ripe in May or June. This I consider to be owing to the warmth applied to the roots of early Vines, a fact which appears to afford proof that a cold state of the roots is the primary cause of shanking. It is about the month of October, or sometimes earlier if the season has previously been wet, that shanking begins to show itself, and this is the time, just before winter protection is put on, when the outside borders become excessively wet, and consequently cold. I venture to think that if Vine borders were protected earlier, and more generally, there would be fewer shanked Grapes. It is before the borders get saturated with autumn rains that coverings should be applied, i.e., when the soil is dry and warm. Cultivators are generally particular about having their early Vine borders not only protected above, but also supplied by heat from underneath, and this until the fruit is fully ripe. Why, therefore, should not the same care be taken in the case of autumn borders. I do not mean

that the soil should be heated artificially, but simply that it should have such protection as will keep the outside roots at the same temperature as that in which the stems are inside. Badly drained borders are in no way different from those exposed to cold rains in an unprotected state. Such borders are never dry, either in autumn or winter, even when covered early in the season. Some attribute shanking to over restriction in the way of foliage, but that I imagine is a mistake. Then again it is well known that shanking seldom affects Grapes produced early by Vines in pots. These are as much restricted in their growth as any Vines could possibly be. With such evidence before us, it is likely that a cold damp state of the soil about the roots is the cause of Grapes shanking. The preventive therefore is well-drained borders and early and thorough surface mulching.

J. M.

BOUGHT VINES BETTER THAN HOME-GROWN ONES.

I CAN assure Mr. Churchill that my statement (see p. 45), that many skilful Grape-growers fail to grow their own pot Vines successfully, is correct—a fact of which I have had ample proof. I can see nothing discreditable in gardeners buying pot Vines at establishments in which their culture has been made a speciality, and in which, on that account, they are able to grow them better than is generally done in private places. In speaking of cutting Grapes from pot Vines in April and May, and giving the total cost of two dozen fruiting pot Vines at £21, does Mr. Churchill imagine that he is proving the buying of pot Vines to be an expensive affair? He is correct about the cost; but, as he is silent about remuneration, perhaps you will allow me to supplement his calculations with reference to that matter. It is not the original cost to which I look for the value of an article, but to the actual worth of the produce. New Grapes are valuable in April and May. The poorest fruiting pot Vine will bear at least 10 lbs. of Grapes, which at the very lowest price are worth 10s. per pound. This brings the return for the £21 to £120; and, deducting the "trade" price (£99), a good sum is left to cover the sundry expenses. The principal expense in forcing winter Grapes is the fuel; but, as a rule, the pot Vines are grown in spare corners of structures heated for other subjects, which would generally otherwise be empty; therefore the cost of firing cannot be wholly charged to the pot Vines. The weights of the Elvaston Castle bunches are doubtless correct; but I may inform your correspondent that I know a trade grower who is in the habit of fruiting the weakest of his canes after his regular customers have had their pick, and yet he cuts bunches from them weighing 3½ lbs.

J. MUIR.

Mr. Muir is wrong in saying that gardeners in private establishments cannot grow pot Vines as well as nurserymen can. I have a quantity now of last year's growth from which I expect our earliest Grapes in April. Some of them only struck from eyes last spring are showing ten and twelve bunches each; others, two years old, have shown as many as twenty bunches. These canes, I was told in July last by a trade grower, were being kept too damp, a statement to which I replied, "come and see them in April," and I hope he will do so. I trust that Mr. Gilbert will give us his experience on this subject; and, as Mr. Muir has cast the first stone at us private growers, let us show him that we can produce as good pot Vines in our own quiet way, as the nurserymen can do in their mysterious fashion.

WM. IRVINE.

Glossop Place, Manchester.

FOREIGN AND ENGLISH GROWN PEARS.

THE large Channel Island dessert Pears shown at Kensington and other places have given rise to the question of the comparative quality of this fruit and that grown in England. This point is frequently mooted by those who see both at the exhibitions, and who read such conflicting statements respecting them in the gardening papers, and the question scarcely admits of a positive reply as regards all the varieties usually grown in England and France or the Channel Islands. Some of the largest varieties, such as Duchesse d'Angoulême, Beurré Diel, Chaumontel, and Van Mons Léon le Clerc, are better in texture and flavour when grown in France or the Channel Islands than when they are grown in England. But if we come to the smaller varieties—for instance, Marie Louise, Louise Bonne of Jersey, Seckle, Doyenné du Comice, Winter Nélis, Comte de Lamy, Joséphine de Malines, Thompson's, Brown Beurré, Knight's Monarch, and others, I make bold to assert that these, which may be taken as representatives of the best Pears in existence, are of better quality when grown in England than any produced abroad. This is not a hasty conclusion formed upon insufficient data, but upon extended practical experience,

close observation, and comparison, not of a single locality, but of the produce of many parts of the kingdom.

Judging Pears.

I would observe that, although we hear so much about the influences of climate upon hardy fruits in the different parts of England (and I am ready to admit that its effects are great), yet these climatic influences upon the quality of the fruit of the Pear are not nearly so great as that produced by the difference in soils; and it is to this difference that I attribute the superiority of the best English-grown Pears over any produced elsewhere. From the finer appearance on the one hand, and superior quality on the other, it becomes a somewhat difficult and unpleasant duty to judge between the home-grown and these foreign Pears on the exhibition table; and it would require a great deal of moral courage on the part of the judges to give the preference to quality over size and general appearance. I maintain, however, that these collections of large coarse Pears have no more right to take precedence of smaller fruit of finer texture and better flavour, than Trebbiano and Barbarossa Grapes would have in being placed before Muscats and black Hamburgs. It would, I am sure, be a positive infliction, even to an indiscriminate lover of fruit, to be compelled to eat these grand-looking, coarse-textured, flavourless examples of Beurré Clairgeau, and others which are little better, upon whose appearance alone the awards are made. The sooner the matter is looked at from a common-sense point of view the better; for it is difficult to see why one standard of excellence should be correct for all kinds of dessert fruit except the Pear, for which another and new one has to be adopted, unless fashion alone is leading us astray. When such things as these enormous cooking Pears, Uvedale's St. Germain, looking like Swede Turnips, are made to do duty on the occasion of large dinner parties, it is not easy to foresee the end. Fine-looking coarse fruit may be tolerated at exceptional times; but if a gardener were to send it on ordinary occasions to his employer's table, he would most likely have them consigned to the pigs, and the trees that produced them removed. From the day that appearance is preferred to quality at our fruit shows, these exhibitions will cease to promote the real advancement of fruit culture. No wonder that the complaints of exhibitors of the splendid collection of English grown Pears seen at South Kensington were loud at being compelled to show against the Channel-Island-grown fruit; they naturally felt that they were labouring under an insurmountable disadvantage in climate for producing fruit so fine in appearance, but were aware that their own were greatly superior in edible qualities, which unquestionably should command the preference. I looked through the exhibition in vain for that finest flavoured of all Pears, the Seckle, and could not meet with a single dish—the exhibitors evidently being under the impression that its small size would count against them; yet I well recollect the time when for single dishes this variety had a separate class made for it, no other sort being able to compete with it in flavour. With few exceptional varieties, Pears when grown large are not so highly flavoured according to their respective kinds as when they are small or moderate in size. This I have repeatedly proved in different soils and widely separated localities; in seasons when such sorts as Louise Bonne, Marie Louise, or others of fine quality bore only a thin crop, and were consequently much larger than when the trees were heavily laden, the fruit from the same trees bore no comparison for high flavour in the large as compared with their smaller state. The question has lately been asked as to the comparative flavour of fruit produced on walls and on standard trees. An answer to this requires to be somewhat qualified. In some parts of England, more especially in the north, a particular variety will succeed well on a wall; but not as a standard. For instance, the excellent Pear Passe Colmar does well in some situations on walls, but the fruit is poor, gritty, and liable to crack on a standard. In localities where varieties of the best quality will do well, both on walls and as standards, the fruit produced by the latter, although generally much smaller, is far better flavoured. This I have invariably found to be the case in different parts of the country.

Best Kinds of Pears.

In planting Pears, very great mistakes are generally made by trying too many varieties, especially of such kinds as ripen in the autumn. It is no uncommon occurrence to find, even in well managed gardens, four times the number of sorts necessary, all ripe during the latter part of October and November, and when Christmas comes there is a scarcity. Winter Nélis is one of the very best Pears in cultivation—tender, juicy, and finely flavoured, coming in when Pears begin to be scarce, about the beginning of the year—and with good management will afford a succession for six weeks. The tree has an excellent constitution, is a free and regular bearer (in this it has few equals), and will do well on a wall in almost any part of England,

where Pears can be fairly grown; and yet, with all its good qualities and the price it commands, it is seldom met with. It is one of the very first fruits I should recommend for planting on the cottagers' gable or the walls of a farmhouse; in fact, I know cottagers whose single tree goes a long way towards paying the rent. Where this Pear will succeed as a standard it should be largely grown for market purposes; and where Pears or any other fruit are grown for sale, the best course to follow is to confine oneself to a few kinds that possess the properties of a healthy constitution, a free disposition in bearing, good quality in the fruit, and if in season when the market is not overstocked with numerous varieties, it will be all the better. As I have repeatedly urged, if there be one thing more than another in rural economy that we lack, it is the extended culture of hardy-fruit. So far as the farmer and cottager are concerned, except in the principal Apple-growing districts, the south of the kingdom is far behind the north in the attention paid to this important branch of industry. Amongst the smaller and more numerous holdings in the northern counties, notwithstanding the disadvantages of climate, the orchard is looked upon as of more importance, and is less frequently absent than in the south. The six following kinds of Pears I should recommend for planting largely:—Williams's Bon Chrétien, a good Pear, and free bearer; Beurré de Capiaumont, a good melting sort, and an immense cropper; Marie Louise, a Pear that for general excellence is not surpassed, will grow and bear well over a wide range of the kingdom, doing well as a standard even in the northern counties; Louise Bonne, of Jersey, equally good in every way, but smaller fruit than the last; Winter Nélis, already described; Brown Beurré, one of the very best late Pears, a good grower and free bearer, but will not succeed as a standard in all parts of the country.

Apples.

The following are half-a-dozen Apples that for free bearing and general excellence cannot be surpassed: Lord Suffield, a large, good, early, and free-bearing kind for cooking, and one that will succeed in any soil or situation where Apples will grow at all; Blenheim Pippin, large bearer, and one that keeps well, and excellent alike for dessert or culinary purposes; Dumelow's Seedling, large-sized fruit, heavy bearer, good keeper, and one of the best cooking sorts in existence; Cox's Orange Pippin, a most excellent dessert Apple, a good keeper and free bearer; Yorkshire Greening, an excellent culinary Apple, free bearer, and fair keeper; Alfriston, one of the latest keeping culinary sorts, large, a good bearer, and excellent. The season for planting is fast drawing to a close. The situation selected should, if possible, be fairly sheltered, otherwise the bloom is more likely to suffer through spring frosts, as also the fruit by strong winds. The soil should be of fair depth and medium consistency—neither too heavy nor too light; of the two extremes the latter is the worst. There must be no stagnant water in the soil; consequently, if wet, it must be drained. A moderately open sub-soil is the best. If of fair quality, the ground should be trenched eighteen inches deep. The application of manure in the preparation of the land has been recommended by some writers; but no one who has had practical experience in the cultivation of these fruits is likely to advise such a process. Land that requires manure in the preparation for planting Apples and Pears is not fit for growing them, and consequently, should not be turned to such purpose; the greatest difficulty experienced in the cultivation of these fruits in private gardens where culinary vegetables grow is with the manure the latter receive, which induces over-luxuriance in the trees.

T. BAINES.

STRAWBERRIES IN LONDON MARKET GARDENS.

THE Strawberry is very largely cultivated around London, some hundred of acres being annually devoted to its growth. In the Fulham Fields but very few Strawberries are grown; indeed, Steel, Bagley, Humphrey, and other large growers in that fertile level, do not grow a single plant. The finest fields of this fruit that I have seen are at Isleworth, Twickenham, Acton, Deptford, and Chiswick; but, in addition to these, there are many small fields of the same all around the metropolis. Kent is famous for its Strawberries; and gardeners in that county, living several miles from London send heavy consignments of this fruit to the Borough and Covent Garden Markets. Unless the soil is suitable for this crop, market gardeners deem it more advantageous to devote their ground to other vegetables and fruits that are likely to be more remunerative. A good sandy loam, rich and moderately moist, is considered the best, as one that is high and dry is liable to become too parched by the summer's drought to ripen a good crop of fruit, and in a tenacious loam the plants are short-lived, and not very satisfactory. The varieties grown for market purposes are very numerous, every grower having his own chosen sorts; but the following are universal favourites:—British Queen and Myatt's variety of the same,

Myatt's Eliza, Mammoth, Eleanor, Keen's Seedling, Old Pine, Dr. Hogg, Double-bearing, Elton, Kitley's Goliath, President, Sir J. Paxton, Sir Harry, and Spring Grove. Many of the gardeners have kinds saved from their own plantations for a series of years, and these have local names; in fact, a good deal of confusion exists respecting the nomenclature of Strawberries in market gardens. One of the greatest recommendations that a punnet of Strawberries in a fruiterer's shop-window can possess is to have the prefix "Myatt's" attached to its name. As soon as the fruit is picked from a plantation, the best of the young plants on the runners are selected for forming a new field, the runners being severed from the parent plants with the spade, so as to make the young plant solely dependent upon itself, but permitting it to remain otherwise undisturbed till a fitting time arrives for its final transplanting; or the young plants may at once be taken up, planted permanently, or in nursery lines, to await a convenient season. This separation of the young offsets sometimes takes place in August, but more commonly in September, and, indeed, it is often delayed till October, when the spaces between the rows are about to be dug over and planted with Cabbage Lettuces. Having prepared the young plants, the ground for their reception—having been trenched and exceptionally well manured for the previous crops—is now dug; and, if need be, re-manured, or the ground is sometimes manured and trenched immediately before planting. The ground being level, lines are marked across its surface 18 inches or 2 feet apart, and the Strawberries planted 18 inches asunder in the rows. Two feet is, as a rule, the recognised distance, especially for strong growing sorts, such as the British Queen, and, in some instances, an additional 6 inches is added to the last distance. Mr. Myatt, of Deptford, in making some of his plantations, lines off his ground lengthwise and crosswise in rows 18 inches apart, inserting a plant at every crossing of the lines, thus leaving them all 18 inches apart each way. After taking a first year's crop, he lifts every fourth row, so as to make an alley for the convenience of gathering from those left; besides it affords the latter more light and room to grow, and the space is not lost, as he crops it with Lettuce or Colewort. Under the partial shade of fruit trees and between rows of fruit bushes the Strawberry is also much grown, although the most favourable situation for them is acknowledged to be an open one. When under fruit trees the distance apart of the plants varies, and depends on circumstances, but 20 inches or 24 inches is the average; one, or at most two rows only are grown between the bushes. For the first year after planting Lettuces, Turnips, or other dwarfed crops are grown between the rows, and even in the winter of after years that space is not unoccupied; although Mr. F. Dancer denounces intercropping Strawberries, still he practises it himself. No care is exercised in their culture beyond hoeing and mulching, the latter being performed in May or June, or early in spring, and consists of the common stable manure, which, after it is washed by a shower, is quite clean. A common way of mulching is to scatter the manure over all the field, covering the plants as well as the ground. This being done early in spring, the foliage rises up through the litter fresh and strong. Gathering is done chiefly by woman, and in dry weather. The fruits are carefully packed into punnets, which are packed in large baskets for the convenience of waggon transit. After the fruit has been gathered the runners are cut away on either side of the rows, and all dirt taken immediately to the centre of the alleys, which are then dug and cropped. A plantation lasts good for three years, bearing sometimes more or less according to the land and the dry or wet summers.—"Field."

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Oranges.—These are now raised in such quantities, and of such excellent quality, in the neighbourhood of Galveston, Texas, that the importation of the fruit, it is thought, will shortly cease at that port.

Cherry Trees Shedding their Fruit.—I have two Cherry trees (Governor Wood and Elton) on a south wall (in a cold wet climate) which blossom magnificently every year, but the fruit never ripens. I have tried all sorts of plans to induce it to do so, such as watering freely whilst stoning, root pruning (they are very vigorous), taking half the blossom off, but all to no purpose. Just as I think I really am going to have a crop they all fall. Can any of your readers help me in this matter?—J. P., York.

Raising Vines from Eyes in Turf.—In reference to Mr. Simpson's remarks on this subject (see p. 80), allow me to say that I have "discovered" nothing whatever to induce me to "retract" a single statement which I have made as regards raising Vine eyes in turf; notwithstanding Mr. Simpson's eight years' experience at Dalkeith, I am assured that the young Vines employed to plant the Lady Downes house there were raised from eyes in turf. Mr. Simpson admits that when he was at Dalkeith Mr. Thomson planted Vines on turves when they were about 18 inches high. Surely, therefore, he must have raised Vine eyes in the same material. But, be that as it may, I can assure Mr. Simpson that I was practically acquainted with raising young Vines in turf before ever I knew that a young Vine had been raised in that way about Wortley. Therefore the "plan which I now adopt" can scarcely be considered to have been borrowed from the system, "exactly as recommended" by him. —J. Muir.

THE KITCHEN GARDEN.

HOW EARLY POTATOES ARE GROWN IN LANCASHIRE.

I LIVE in a part of the country where nearly a whole parish, and portions of several others, are occupied in growing early Potatoes in a manner scarcely known, I think, elsewhere, and certainly worthy of imitation where this vegetable is largely required. Cottagers, large and small farmers, and nearly every occupier of land, have more or less to do with their production; and when I tell you that £70 was offered for the early Potatoes growing in a cottage-garden, on a piece of land that would not half support a cow, and that some of the growers have about a quarter of a mile, or upwards, of pits for the purpose (they are grown in pits), the affair must be considered important. So much so, that I have often wondered

Fig. 1.

that the custom is so local. Perhaps when I mention that the neighbourhood where these early Potatoes are grown closely adjoins the district where the Potato was first cultivated in England, the subject may be rendered more interesting. The early Potatoes are grown in turf pits, covered with straw screens that are made in a peculiar manner. To the making of these screens I shall first direct attention, and in order to render my description more intelligible, I have prepared a few sketches of the process. Let a carpenter make a strong frame, 6 feet by 4 feet, which shall, when shut, resemble a monster kind of book-cover in two parts, which are hinged together strongly at the back, and fastened with hooks and staples where the book-clasps would be (fig. 1). The pieces forming the back, where the hinges are placed, and the front, where the bolts are used, should be of Oak, 2½ inches thick, and 6 inches wide. A piece at each end, and two in the middle, also of Oak or Ash,

Fig. 2.

1 inch thick, are let into the pieces forming back and front, leaving between the "boards" a space 3 inches deep, which is intended to contain the material of the screen, or what would be the letter-press of a volume. Procure two tressels on which to place the frame—each tressel, when in position, having a post, or stout piece of wood, 6 feet high, let firmly into the ground at its end (as fig. 3). When the frame is laid on the tressels, one part is turned up and fastened to the posts (as at fig. 2). On the part of the screen that lies on the tressels, prepared pieces of tough branches of wood, such as Hazel, Oak, dead Spruce, Larch, or any durable young wood, are laid, and on the toughness of the brush employed, depends the durability of the screen. Such spray as that of Beech, Elder, &c., is of no use, as it only lasts one season, and when the wood is worn out the screen is comparatively useless. Now place on the wood long Wheat straw, to the thickness

of about an inch, equalising it over the whole frame, and making both ends full. More branches of a stronger kind are then laid on, keeping some of the straighter pieces for the outsides, and using three strong pieces cross-ways, to give strength. It is this middle enclosed brushwood that gives a firmness to the whole, and makes the screen as solid as a table-top. Add another layer of straw as before, on which place some of the flatter and lighter pieces of spray, as at first. Now bring down the turned-up part of the frame, and bolt together, as at fig. 1. Some amount of pressure will be required, owing to the mass of straw and wood employed, but this gives firm-

Fig. 3.

Fig. 4.

ness to the screen. Turn the whole of the screen up to the two posts (fig. 4), to which it is fastened at the top, the lower part still resting on the tressels. Tared twine must now be in readiness, with two needles made of hard Oak, a foot long (fig. 7), with perforated eyes, and a man on either side of the screen passes them through in three or five places, as at E (fig. 4), exchanging needles at every stitch thus forming a kind of brace-stitch (fig. 5). When this operation has been completed, twist off the ends of the brush and straw flush with the ends of the frame, and you have the screen represented in fig. 6. Although I have merely alluded to these

Fig. 5.

Fig. 6.

Fig. 7.

appliances as being largely used for early Potato growing, they are amongst the most useful articles in a garden. Placed at an angle of 45° over Celery rows, they would effectually protect them from wet and snow. Round early-made hotbeds they are also invaluable. Supported on bricks over Parsley-beds they afford protection in all weathers, and neither staking nor nailing down will be required. Early Vine borders may be thatched over with them, and three or more placed around shrubs will afford them a neat and efficient protection. Many other uses will suggest themselves. Temporary pits to any extent may be made with them; or, by laying them end

Fig. 8.

to end, tied to stakes, they furnish capital places for hardening-off bedding plants. They can be made by any labourer; and stowed away, when dry, under a shed, will last for years. Where used extensively by the Potato growers they are made into stacks and slightly thatched over till wanted. I will now proceed to explain the method of raising the Potatoes. These are grown in pits made of turf. The best and most sheltered situations adjacent to the dwellings of the growers are chosen; a good thick high hedge running east and west is a good site, or a sheltered piece of land is often wholly occupied by a series of pits running parallel to each

other; in short, naturally warm places are always chosen, and if they do not exist they are artificially made so. The pits are constructed of any required length from the sods on the place. The walls are 1 foot thick, 1 foot high at the back and front, and 4 feet high at the ends or gable; they are about 8 feet wide; a slight rail, answering to the ridge tile of a building, runs the whole length, supported, where necessary, by upright pieces, which, of course, run down the centre of the pit (fig. 8 A). A more slender rail, or even tar twine fastened to upright sticks, runs parallel with the ridge piece, midway between it and the walls, both at the back and front (as at B). Of course a slight rail is preferable to the twine, where obtainable. The use of the latter is to prevent the screen (one end, of course, resting on the wall and the other on the ridge piece) from swagging downwards with the weight of wet or snow. I will now suppose the pit to contain a sufficient quantity of highly manured soil, and to be ready for planting. The most important item, however, in the whole affair is the preparation of the sets, and this is peculiar and totally at variance with the directions usually given for the sprouting process of growing early Potatoes. The system generally advocated is to push the set into growth only for 2 or 3 inches, and then by exposure to green the sprout. In the method I am now endeavouring to describe the main point is to keep them white and tender, just as they would be when buried in the soil; and the theory is, that this is effected by keeping the

Fig. 9.

Fig. 10.

sprout continually growing from the first. Any greening or hardening is considered detrimental and a waste of time. On consideration, it will be evident that a Potato sprout that is greened and hardened before planting must become blanched and softened before it commences to grow. Laying down—that is, putting the Potatoes to sprout—commences about Christmas Day. A hay loft or barn floor, or any spare room, is used for this purpose. Selected medium-sized whole Potatoes are used, and placed as close together as they can be packed singly. Bricks or pieces of wood are placed at convenient distances as the Potatoes are laid down, serving as alleys. On these, slight slips of wood are placed over the sets, and the whole is covered over with stout paper, such as old newspapers, &c. This is done to exclude light and air, and acts as a kind of forcing process with the Potato. Hay or litter is placed over the paper in frosty weather. This method is a rather dangerous one in hard frost, especially in such a winter as we have just passed through. A modification of it, certainly to be preferred for general purposes, is to use light-made 9-inch-deep boxes, 4 feet long and 2 feet wide, with no tops (fig. 9). These are filled with Potatoes, as on the floors, and are piled one on the other in any convenient place. Being all of one size, the bottom of one serves as the top to the other. Old Orange boxes are well adapted for this purpose, and do well where they can be had. The sets, by this method, can easily be protected from frost, as, in extreme weather, they can be carried anywhere—they are sometimes put in rooms under beds. Planting time commences on Valentine's Day, the screens having been placed on the beds a few days previously to keep the soil dry, and the sets are uncovered on the floors or in the boxes for about three days, to give the sprouts a certain firmness. They are cut up as planted, each set having one good sprout about 6 inches long. Scrupulous care is taken to reject every sprout with a hard or black point. Holes are made all over the bed, 9 inches every way, with a kind of dibble shod with iron (fig. 10), which, owing to a cross piece (C), can only make the hole the required depth. One Potato is placed in each hole, and then the whole pit is raked carefully over with a wooden rake, or hay rake, which, as the sprouts are barely half an inch below the surface does not break the points. The

back screens are then put on from end to end, the ends on the ridge being kept true to each other, so that the front screens, when put on, form a good lap on the back ones. The work, as far as planting goes, is now done, and, as the Potatoes have had no check, they are up directly. The front screens are taken off every warm sunny day that comes, and put on early in the afternoon, always according to weather—and now the care begins. No sunny day must be lost, and a frosty hour would be fatal. It would be useless for anyone to attempt growing Potatoes largely on this plan, except they can afford to have some person nearly always with them. Small farmers or cottagers, with stout lads and lasses, generally follow it. A ton of screens to lift off in the morning, and put on again in the evening, is labour, and those who cannot afford cheap labour do not attempt it. The back screens are seldom taken off till the Potatoes are far advanced, or when rain would be beneficial, and the front ones, when taken off, are laid down sideways, tile fashion, but always below the level of the front wall, so that a single ray shall not be intercepted. The back screens being kept on, not only keeps the cold and the winds away, but prevents the heat entering on the unclosed or open side from being lost by radiation. It is a strange sight to see these Potato beds up and green in the open air in April. The Potatoes are ready early in May, and are packed in neat hampers, each containing 20 lbs., which sometimes realise 1s. per lb., which is thought a good price. They are bought up by dealers, who convey them to the manufacturing towns, Bolton, Barnsley, Blackburn, or Manchester, and quite an ovation is paid to the person who takes the first consignment to market. Innkeepers, shopkeepers, and others, present him with pieces of ribbon of every possible pattern and colour, which are pinned on every available portion of the dress, so that I have seen these men come back from the market thatched, as it were, with ribbons. Thus I have described at length, but I trust clearly, the practice followed to a very great extent by cottagers and small farmers. Gardeners will at once see the value of this system as the means of raising an intermediate crop between those grown under glass and warm borders in the open ground, and there is no doubt that these pits, in large gardens, could be utilised for other crops after the Potatoes. What a charming place for salading in parching summers, and what capital places to protect such plants as Lettuce or Cauliflower till the middle of February! No such use, however, is made of them by the Potato growers. When the Potatoes are off, the soil is thrown up into a high side, from end to end, and remains so till planting time comes round again.

THOS. WILLIAMS.

Bath Lodge, Ormskirk.

Mushroom Culture in Tan.—It may be of interest to some of your readers to know that Mushrooms can be grown in tan. I have grown them with great success, for three successive years, in tan which had been used for hunters to trample on through the summer, and of course there is some of their manure incorporated with the tan. The genial heat that the tan gives renders it one of the best materials that can be used for the growth of Mushrooms. When well beaten together with the horse-dung, and in sufficient quantity, I find the mixture more productive and lasting than horse-dung alone. The beds are, in fact, masses of clumps with as many as from twenty to fifty in each, which could be and were often taken up whole. Some may ask, Does not tan produce unwholesome fungi? With me, and used as stated, there need be no fear of this; I have not found one spurious one. As to flavour, they were pronounced by those who partook of them to be very savoury and delicate. It must not be inferred that I recommend tan alone, but let a quantity be put in a loose box, or any other suitable place where a horse is shut up for a time, so that its manure is well incorporated with the tan, and use it when in a good friable state, neither wet nor dry; if too wet the spawn will not run so well, and if too dry the beds will not keep in bearing so long. My experience leads me to think that tan will be much sought after when its qualities are more known to Mushroom growers, for I believe it to be superior to all droppings. —CHARLES PENFORD, *Meynell Langley, Derby*, in "Gardeners' Chronicle."

GEORGE II. having ordered his gardens at Kew and Richmond to be opened to the public during part of the summer, his gardener, finding it troublesome to him, complained to the King that the people gathered the flowers. "What," said the monarch, "are my People fond of flowers? Then plant some more."

THE FLOWER GARDEN.

PEONIES.

MR. BARRY, in a paper lately read before the Rochester Horticultural Society, made some remarks on these fine hardy plants, which are worthy the attention of all interested in hardy flowers. At the present time no class of plants of equal value is receiving less attention than Peonies? Is it because they are too well known, and therefore common? We cannot concur in any such opinion; and if we can do something towards awakening and reviving interest in this, one of the most striking and valuable floral productions of China and Europe, we shall be pleased. Peonies are commonly divided into two classes, Tree and Herbaceous, the latter being again divided into sub-classes. The Tree or Moutan Peonies are natives of China, and were first noticed in the year 1656, on the return to Europe of the first embassy of the Dutch East India Company. The attendants of this embassy having had freer access to that country than had been granted to any previous embassies, visited all the country from Canton to Peking, even the gardens of the emperor, and as the result of this visit, published a work describing among other things the Pine-apple, the Tea plant, as well as the magnificent flower of the Moutan. This volume, however, received little attention, being considered only as a collection of traveller's tales. The description of the Peony therein given was very full and complete, but the plant remained unknown in Europe until the late Sir Joseph Banks gave instructions to several merchants trading at Canton to inquire for the Moutan, and numerous plants were imported in the year 1794. It is said to have been cultivated in China for upwards of 1,400 years, and some of the Chinese authors say was first discovered growing among the mountains in northern China, whence it was brought into the southern provinces and there cultivated with the same enthusiasm as Tulips have been in Europe, some choice varieties of the Moutan having been sold in China for 100 ounces of gold. The Tree Peony sold at high prices when it first came into the hands of nurserymen in Europe, Monsieur Jositer, in Paris, receiving for plants of it more than 300 dollars each. This Moutan is the parent of most of the beautiful varieties of Tree Peonies now cultivated. Tree Peonies fill up a blank between deciduous flowering trees and flowering shrubs. In mixed borders they are invaluable, as well as single specimens on the lawn. They are quite hardy, but slight protection greatly improves them. They thrive in any good garden soil enriched with well decayed manure. September and October are the months best suited for their planting, but if in pots they may be put out in spring, when all danger of frost is over. Good plants set in autumn produce quantities of flowers the second or third year after planting. Each year the plants increase in size and beauty, and soon become the most showy and attractive features of the garden. They are the first of any of the varieties of Peonies to flower, and put forth their blooms early in May. Being naturally of what is termed slow growth, they are not propagated by division to any great extent, but chiefly by grafting upon the roots of the herbaceous varieties, which is done in August. The grafts are placed in frames, where they unite, and are transplanted the succeeding year into many rows.

To assist those who desire to form a collection we name the following choice sorts. Any description, however complete, would fail to do them justice; so we give only the distinguishing colours.

Moutans.

Alba variegata—One of the most striking double varieties. The outside petals are pure white and the centre pure flesh-red.

Arethusa—Light rose, shaded with purple; this is a very large and fragrant variety—and a vigorous grower.

Banksii (Chinese double blush).—Flowers pale rose-coloured, from 4 to 6 inches in diameter.

Gumperii—One of the finest kinds, producing bright rosy-pink flowers of great size and perfection.

Incarinata (double).—A fine white variety; flowers large and fragrant.

Rochlerii—A choice dark rose-coloured variety. Blossom large and plant vigorous.

Le Fevreiana—A very large and showy variety; flowers bright pink, with rosy centre.

Pride of Hong Kong—A striking variety; flowers of great size, light cherry-red with purple centre.

Queen Elizabeth—Blooms of immense size; rosy-crimson in centre, shading off to a light rose toward the margin.

Rosea odorata—Rose tinged with lilac, very large and flat.

Schultzi—A beautiful and fragrant kind; flowers carmine coloured, deeply shaded with rosy-lilac.

Zenobia—A large fine white variety.

Herbaceous Peonies.

Some beautiful varieties distributed a few years ago by the Royal Horticultural Society may also be found in English gardens. These are usually classified as officinalis, paradoxa and the Chinese varieties—the two first being European and the third Chinese sorts. These flower in succession, the first being the officinalis varieties, then the paradox, and the Chinese last. The Chinese varieties are particularly fine, and we regret not being able to give such a description of them as would induce every person who is the fortunate possessor of a garden to plant the entire collection. Herbaceous Peonies increase rapidly in size, and soon form a large clump, and thus, like all herbaceous plants, they should be divided occasionally, and the thriftiness of the plants will thus be greatly promoted. The most gorgeous floral exhibition we have ever seen was an acre of Peonies in full flower. Will you therefore allow me to furnish you with some notes made on the ground?

Ambroise Verschaffelt.—This is one of the newer kinds, and up to the present time one of the best dark varieties known. The flowers are purplish and full.

Carnea Striata.—Flesh colour striped with red; very fine.

Charles Verdier.—Another new and superb variety producing light lilac-rose flowers of great size and perfect form.

Delachii.—A striking and beautiful dark variety; flowers, purplish-crimson.

Festiva.—This is a sort which cannot be too highly praised. Imagine a plant 3 feet high, with beautiful dark green glossy foliage, and peering above it from ten to fifteen large heads of bloom, each from 6 to 9 inches in diameter, pure white, marked here and there with bright streaks of carmine, just enough to show how pure the white is, and how beautifully the carmine contrasts with it. Match this with an Ambroise Verschaffelt or a Delachii, and you have a picture, or a pair of them, fit for the greatest amongst us to admire, but within the reach of the humblest to possess.

Grandiflora carnea plena.—A variety of extraordinary size. A nursery row of this, with hundreds of enormous white blooms edged with blush, is a sight worth travelling miles to see.

Humeri is another kind which has large and showy purplish-rose flowers of great beauty.

Jules Lebon.—This has brilliant and distinct carmine-red flowers.

Louis Van Houtte.—One of the dark crimson sorts, which produces a marked contrast among the fancy-coloured varieties.

Louis Van Houtte (Caleb's).—Bright purplish-cherry, and a charming sort.

Marechal Vaillant.—A new kind, of a dazzling purplish-violet colour.

Madame Victor Verdier.—Crimson-rose, with light violet, very large and full.

But we have now given enough, we hope, to induce cultivators to turn their attention to these showy and really interesting plants.

Variegated Bedding Tropæolum Minnie Warren.—I am quite at a loss to understand why this extremely beautiful, easily cultivated, and in every way most thoroughly satisfactory foliage bedding plant, is so very seldom seen in our gardens, where, were its beauty and great merits but once known, I cannot but think it would soon become a universal favourite. This charming plant was raised as far back as 1869, by Mr. Cattell, of Westerham, and, when shown the following year at South Kensington, was most deservedly awarded a first-class certificate by the floral committee of the Royal Horticultural Society. It is accurately figured in Vol. IX. of the "Floral Magazine," plate 506, and is there described by the Rev. H. H. Dombrain in the following terms:—"It is, as will be seen by our plate, exceedingly dwarf in character—in fact, of a regular Tom Thumb habit of growth; the ground colour is green, blotched and broadly margined with pale cream, which bleaches to pure white as the leaves reach maturity. It is perfectly constant in its variegation, and very seldom produces blossoms—another great merit in a foliage bedding plant." When, however, it does bloom, and is allowed to seed, the seedlings come quite true to the beautifully variegated character of the parent plant. When bedded out in a scroll or pattern bed with a line of Iresine Lindeni, on either side the contrast produced between the two plants has a most striking and pleasing effect.—W. E. G.

Primula altaica.—The plant referred to as *Primula altaica* (syn. *grandiflora*), at p. 90 of your last number, is not *P. altaica*, but a variety of *P. vulgaris*. *P. altaica* is closely allied to *P. farinosa*, and has very narrow leaves (not half an inch wide), and umbels of numerous small flowers in the style of *P. farinosa* and *P. sibirica*. It is probably not yet introduced into Europe. The variety of *P. vulgaris* referred to has long been erroneously called "altaica" by horticulturists. Why? Probably "no one" can tell.—JAS. BACKHOUSE, York.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Forcing Early Potatoes and Carrots.—Look to the seed Potatoes that were advised some time back to be placed in shallow boxes for sprouting and planting next month; they should now be pushing strong sprouts hard and green, that is if they are in a place in which they can receive sufficient light. They will generally get enough if the boxes are placed under a greenhouse stage or on the floor of a cold Vinery, or in a shed or empty room of any sort where there is enough light to prevent their drawing up weakly. Some stable manure and leaves in equal quantities, if the latter are at hand, should be got ready to make up slight hot-beds for early Potatoes and Carrots. Let these fermenting materials be well shaken together and allowed to lay for ten days or so, turning them over once during that time to sweeten, then make up the beds about 2 feet thick, and at once apply the frame, in which put about 10 inches of soil in a moderately dry state, and plant about 4 inches deep any early Kidney varieties. These are the most suitable for forcing, as they do not make such large tops as some others; place the tubers 10 inches asunder in the rows, which should be 14 inches apart; room will thus be left for a thin crop of Radishes, which should be sown at once over the surface, raking in the seed. There is not much danger of a bed of this kind getting too hot, yet overheating does sometimes occur, thereby injuring the Potato plants that are in the centre. When the bed is made and soiled insert a trial stick right down in the middle of it; this can be drawn out daily for a week or two, and felt so as to ascertain the heat, which should not rise above 70°. If there is any doubt about the temperature, plunge a thermometer in the bed, and if it indicates more than the heat just named, get a stout stake and drive it right into the sides of the bed to the centre in several places, leaving the holes so made open for a few days so as to allow the heat to escape. A bed for Carrots (Early French Horn is the best for forcing) may be made, and soiled to the same depth as for the Potatoes. Let the seed be sown at once in rows 8 inches apart, covering it with half an inch or so of soil. If a good body of warm leaves is at hand, the dung may be dispensed with altogether, or not more than a fourth of it need be used, in which case the beds may be made up at once without further preparation of the materials, as leaves are not liable to get too hot. Give air every day as soon as the crop appears above ground. If there happens to be a deficiency of autumn-sown Cauliflower or Lettuce plants, a few seeds of these may be sown in pans or boxes, and placed in beds such as the above, where they will soon vegetate, and when large enough to handle they should be pricked out in a frame or under hand-lights, from which they should be afterwards transferred to the open ground.

Cucumber Beds.—Where there is no other convenience for growing Cucumbers except in ordinary garden frames, stable manure should at once be prepared, as advised for the preceding beds, using, if available, half leaves mixed with it, and the heap should be turned over once or twice until it is in proper condition for making up into a bed. If the plants have to be raised from seeds in this way, it is best to make up a bed for a single light frame, in which to raise them, and when the plants are large enough, as this bed becomes cold, to have a larger one in readiness in which to grow them. The bed in which they are raised should not be less than 4 feet in thickness and 1 foot larger than the frame on all sides; by this means it will keep hot longer than it otherwise would do. As soon as the internal heat of the frame subsides to 80°, sow the seeds in small pots, two or three in each; keep the plants when up near the glass, and give a little air on mild days, covering the glass with double mats at night. Where such a bed as this exists, quantities of cuttings of summer bedding plants may be struck in it and then hardened off.

Walks and Weeds.—By this time most of the winter manure and soil-wheeling on the garden walks should be over; and, where the gravel has got black and unsightly, 3 or 4 inches of the surface should be turned, and, if deficient in gravel, some should be added to the top, giving the whole a thorough rolling as the work proceeds. The walks in a kitchen garden, where anything approaching an orderly system of gardening is attempted, should be as well drained and constructed as those in the pleasure ground. Now is the best time to go over walks generally, and hand-pick all weeds, whilst the surface is soft. Market gardeners who grow for profit, and who, no doubt, calculate the return they expect to get for every shilling they expend in labour, set an example in respect to weeds that amateurs and others would do well to follow. With them it would be a difficult matter at any season to find a bushel of weeds on an acre; their system is to destroy every weed as soon as it vegetates, by frequently running the hoe over the ground.

Fruit Buds and Birds; Pruning and Training.—During this month birds often greatly damage the bloom buds of

bush fruits. See that the trees that were threaded over some time since, or syringed with lime and soot-water, are effectually protected; if the thread has become black, or been removed by the wind, run a few more strands round each bush, or apply more of the lime mixture with the syringe. Such appliances cost little in labour or material compared with the loss of a crop of fruit, and permanent injury to the trees by the bloom spurs being destroyed. Standard Apples or Pears that have been planted through the autumn and winter, even if staked at the time, should be examined to see that it has been done effectually before the March winds begin to blow, for they will be injured if not well secured. Peaches, Nectarines, and Apricots, on open walls, will require immediate attention in the way of pruning and nailing, for if these operations are deferred too long the buds get so prominent as to be knocked off in quantity during the progress of the work. Apricots, bearing, as they do, a good deal on spurs, do not require so free a use of the knife as the others. On the contrary, as much of the wood should be nailed in close to the wall as possible, as on a frosty night the bloom thus situated will frequently escape, where such as is further from the wall gets destroyed. Do not leave the shoots of Peaches and Nectarines too crowded, and, in pruning, reduce the shoots to something like two-thirds their original length, as near as may be, always cutting to wood buds, which are easily discernable from their long pointed shape as compared with the round blossom buds. If the shoots are strong, they will contain numbers of double bloom buds, with a wood bud in the middle, this centre bud will form a leader to the shoot, without which the fruit will not swell freely. Sufficient foresight should always be exercised in pruning Peaches and Nectarines, to see that provision is made to supply the trees in all parts with young wood for the coming year, that is, by cutting a sufficient number of the last season's shoots out to near the point from which they spring, and where there usually exists several wood-buds, the best placed of which should be grown on to form a shoot for tying in the following year, in place of older wood, which it may be advisable to remove. For the same reason, in pruning at the present time, it is well to cut out any long straggling branches that have no bearing wood upon them, except near or at their extreme points. In pruning these trees, obviously, the first consideration must be the current season's crop, but at the same time, by a little forethought, the operator will easily see where it is advisable to encourage a shoot for next year's bearing. It is the want of this kind of attention that reduces numbers of these trees to nothing but strong bare wood, unfruitful except at the points of the shoots. Young trees are in the same way often spoiled by leaving the strong shoots too long, instead of shortening them well back. It should always be borne in mind that at whatever point the shoots of such trees are cut back to from that point, several young shoots will usually push, but not lower down nearer the base; consequently it will readily be seen where next year's shoots should be induced to spring from, so as to properly furnish the future tree. As soon as a tree is pruned, nail it at once. The right way to proceed in this is to begin in the centre of the tree, taking a branch straight upwards, selecting for this, as near as the eye can decide, the one that will leave an equal portion of the tree on each side, and nail this in regularly over the allotted space. This applies, in pruning and nailing, to both dwarf and standard trees of these fruits. There is another matter to which the amateur should always attend, and that is, never to nail the shoots too tightly. Every shoot ought to have double its thickness of room allowed in the shreds, so as to admit of its thickening. It is also most essential not to bruise the bark, as there are no trees so liable to gum, if the bark is bruised, as Peaches and Nectarines.

Shrubbery Borders.—In the shrubbery, the removal or planting of any deciduous trees or shrubs should at once be completed, otherwise the season's growth will not only be sacrificed, but the health of the trees endangered so much as to make it advisable to defer such work until the autumn. In any place that is well kept, and no weeds allowed to grow amongst the shrubs, there is no necessity for digging between them, which, except with the object of burying weeds, is much better left undone, effecting, as it does, nothing but destroying a large quantity of the best surface-roots; however, where weeds have been permitted to get ahead, there is no resource except digging, for to hoe and remove them robs the land, and much soil is unavoidably carried away in the operation; consequently, where shrubberies are very weedy, they should at once be dug, going no deeper, however, than sufficient to bury the weeds and not mutilate the roots.

Glasshouses.—In the stove, greenhouse, and pits the work will consist principally of watering and in giving air, which, if the weather is mild, may be admitted in greater quantities than hitherto; side-lights should not, however, be opened when the wind is strong, so as to admit a chilling current amongst the plants.

BAGATELLE—BOIS DE BOULOGNE.

THE picturesque style of gardening as seen round Paris is mainly distinguished by its tempestuous undulations. In the Champs Elysées every patch of turf is waved up and down in the most violent manner. The adjacent level lines of roadway, footway, or buildings, contrasting abruptly as they do with all this, show its artificial character at once. When valleys are traced through bits of turf not much larger than a dining-room floor, and surrounded by wide level walks, we get the puerile instead of the picturesque. One might as well attempt to diversify the surface of a dinner table. In addition, the undulations are stiffly and badly carried out—scarcely an easy, natural gradation is seen. Sir Richard Wallace's garden, in the Bois (a view in which we now publish), offers, in this respect, a pleasing contrast to the many places in which the above-named blemish is conspicuous. Here we have broad easy glades, so gently, though artificially, hollowed, that they never even suggest the artificial or the incongruous. Here, too, may be seen most artistic and successful attempts to open up long and charming views, both in the garden, and from it into the surrounding country. Happiest of the features, however, is the way these glades and vistas are planted. Instead of the usual plum-pudding-like mixture everywhere, we have the small groves of distinct trees, with the turf spreading beneath them; beautiful natural-looking groups of various choice trees, and sometimes a small group of one kind, only there is not a trace of the dot-a-tree-everywhere system, by which so many garden-landscapes are spoiled. The consequence is that open breezy turf carpets abound, and afford a foreground from which the various beauties of trees or shrubs may be seen to advantage at hand or at a distance. Groups of Yuccas are effective here; also groups in threes of various tree Peonies and other fine hardy plants. Many of the older trees, with high stems, are clad with a mantle of Irish Ivy, which, however, is confined to the bole only. This, when planted against well-grown trees, does not seem to do any harm to the health of the tree. Where a number of tall trees thus covered occur, one may sometimes fancy (seeing only Ivy-clad boles) that it is an evergreen grove, the heads of the deciduous trees being high overhead. This is one of the many effective uses made of the common Ivy here. By the way, tree Ivies worked high as standards, are now seen here and there in Paris gardens. Two large groups of artificial rock here are the most successful we have seen in France; one is a very old group, the other new, both so gracefully embellished with suitable plants, and so well supplied with masses of trees and shrubs that they have a picturesque and, in every way, satisfactory effect in the grounds. Here, however, as in other places, no attempt is made to grow the true Alpine plants in or near these inviting positions; that is work for the future. Where there is so much to praise, we venture to point out that the artificial water here, as in too many gardens, is rather too much after the duck-pond pattern—too abrupt in its margins, and too near the house. With a graceful bend of the Seine glistening through one of the vistas, it would have been wiser to have dispensed with artificial water. Such contrasts remind us of the full moon and stars calmly shining down on a poor mundane illumination.

Gas Heating.—I am about to erect a greenhouse 20 feet by 15 feet, and am anxious to know if it can be safely heated by means of a gas stove. A friend of mine has heated a smaller one in that way, but, as it has not yet stood the test of experience, I am desirous of knowing what you think of the plan. His stove is about 3 feet high and 15 inches in diameter, with two sets of burners at the bottom, and a 3-inch zinc pipe from the top goes round three sides of the house and out at the roof; there is a small pipe to let air in at the bottom of the stove, and the orifice is protected by a little wickerwork to prevent too strong a current of air from blowing out the gas. The advantages of the plan are obvious, as there is nothing to be done except light the gas, and in a few minutes the temperature rises to any required degree, according to the number of jets turned on; and, as gas is cheap here, say 3s. 6d. per 1,000 feet, I presume it would be much more economical than coal. I may add that the cost of the stove and piping, complete and fixed, was £5 10s.—EDGBASTON. [A similar system of heating has been in operation in a small house, near London, for several years, and is found to answer satisfactorily.]

Amadou.—This frequently goes by the name of German tinder, and is employed in procuring light speedily. It ignites immediately with a feeble spark from the flint and steel, or by condensation of atmospheric air, and burns with slow and smouldering heat for a considerable time. It is formed of a spongy excrescence or Fungus found on old trees, particularly Oak, Ash, and Fir. This is washed and boiled in water, and afterwards beaten with a mallet, until it resembles very spongy leather; it is then soaked in a saturated solution of saltpetre, and dried in an oven.

VIEW IN SIR RICHARD WALLACE'S GARDEN IN THE BOIS DE BULOGNE.

THE INDOOR GARDEN.

HARDY PLANTS UNDER GLASS.

HARDY plants, to me, are quite as interesting as the gorgeous Orchids for which my more wealthy neighbours give fabulous prices. They are inexpensive, and I can grow them myself in my own way. In my greenhouse—or, rather, in my hardy house, for I have neither hot-water pipes or air flue to heat it—I am in no concern for my plants should severe frost prevail, for a few sharp pinches at night will not injure them. When a change comes, and the sun now and then peeps out and warms the air, a reaction takes place, and the bulbs burst rapidly into life, the blooms expand, and from that moment until the heat of summer compels me to transfer them to cooler quarters, I enjoy their beauty. In early spring especially, whilst, as yet, flowers are scarce in the open ground, they fill a void for which other plants are not available. My hardy plant-house is not an ordinary building, with the usual fittings of shelves and stages. It is merely a span roof, rather low than otherwise, with a door at either end. The inside is composed of earthwork and a rugged stone formation, having a semicircular border on either side, and a raised mound in the centre. On this I have permanent patches or dressings of the evergreen Sedums intermixed with a few hardy Ferns, and then in every possible, and almost impossible, place are planted out or plunged in pots all conceivable kinds of hardy spring flowers, but all are so placed that they can be liberally supplied with water and kept growing as vigorously as in cool borders. As I have a good water supply with a fair pressure, I have a stopcock placed in an unostentatious fashion in one corner of the house, and, when it is necessary, merely affix my gutta-percha hose, I turn on the water, and give all my plants a generous soaking in a short time. Remembering that if these plants were growing in the open borders the soil about them would, all the winter, be full of moisture, I keep the soil of my house moderately moist, and when the plants spring into activity they get a more liberal supply, especially when the days increase, as they do now, in length and the atmosphere becomes drier. I have the roof of my house constructed of light rafters and with moveable glazed lights. When the hot weather comes the latter are removed, light frames covered with tiffany take their places, the side sashes are removed, and the ends of the house shaded. I thus secure a cool and pleasant place in the summer months, plenty of air, whatever rain happens to fall, and a grateful shade. My glazed lights are placed on a temporary framework and under these I grow Cucumbers, Melons, and Tomatoes, besides raising seeds of choice hardy plants that thrive better under the shelter of glass when in their youthful state than when exposed either to heavy rains or the scorching sunshine. My house is now gradually developing its beauties. Patches of the blue Scilla and white Snowdrops are bursting through in humble rivalry, with Primroses of varied colours, white, yellow, mauve, red, lilac, purple, and crimson; and Polyanthus equally varied in hue. Double Primroses are also throwing up their numerous flower buds; the crimson, pink, and white-flowered variegated Daisies I specially admire for their foliage. Then there are already in bloom some half-dozen kinds of the lovely *Anemone hepatica*, and the *Myosotis dissitiflora* is bursting its buds of cerulean blue in all directions, before long its small brilliant bunches of flower will have appeared. Strong plants of the trailing *Lithospermum*, that have shown a few of its deep rich blue blossoms all through the winter, are here, and patches of the hardy white *Polygala*, besides the creeping *Daphne*. Then are seen Violets, single and double, Violas, and Pansies of different hues, and hardy Primulas in great variety. Just showing the bud are *Cortusoides amœna*, *C. lilacina*, *C. grandiflora*, and *C. alba*; and *C. nivalis*, *C. intermedia*, and *C. alpina* somewhat more advanced. Then I have *Arabis albida præcox*, which is in full bloom—the variegated kinds pleasing in their foliage—and rosea giving promise of good heads of flower at a later date. The white and pink Christmas Roses have thrown up fine and showy blossoms, and the *Aubrietias* are following suit—*Aubrietia variegata purpurea* is at all times a gem, but is especially so under glass. Then early dwarf kinds of the *Iris*, *Saxifrages*, and creeping

Campanulas afford plenty of groundwork for the choicer kinds of *Crocus*. Lastly I have Tulips, with *Narcissus*, Grape Hyacinths and the *Triteleia uniflora*, but even these do not constitute all the inmates of my hardy plant-house. I labour to fill it as much as possible with early-flowering plants, for these at the commencement of spring are much rarer than in the month of June, besides which they are not so lightly heated by the elements as during these later months. Then I can be ever changing, for it is needful each autumn that there should be a re-arrangement of many plants, some requiring dividing, some re-placing, and others must be laid aside altogether in favour of new comers that I may have been fortunate enough to add to my collection. I find it is well to have a reserve in the open ground of small stocks of most of the choicer plants, as some may die or need removal into the open ground for a year to enable them to recruit their crowns; but, as a rule, they all thrive well, and I attribute their general health not a little to a constant supply of water, cool shade in the summer, and liberal top-dressings of rich soil and cocoanut fibre, which is one of the most valuable mulching agents for flowers that can be found. Being somewhat of an enthusiast for spring flowers, and, indeed, for hardy plants of all kinds, I am often not a little vexed when I see my friends throwing away their yearly allotted garden money on tender soft-wooded stocks that the first frost will decimate. I would, if I knew how, endow them with some of my love for these hardy gems. Perhaps my present work may tend some day to accomplish this, and I should seek my reward in the knowledge that I had contributed in no small degree to an enhancement of their own pleasures.

D.

EURYA JAPONICA VARIEGATA.

THIS finely variegated Japanese plant should be as generally grown for the decoration of cool conservatories as the different varieties of *Croton* are for that of the stove; it is easily propagated by means of cuttings made from the points of the shoots, struck in sand in heat, and then potted on in either sandy peat or good loam. It will succeed in either, being, like almost all Japanese plants, not at all over-particular as to the soil it requires; but with this, as with other plants, there is a vast difference betwixt the progress it will make if well attended to and pushed on by re-potting as required, and the comparative slowness which plants show that only get a periodical shift once a year, as is too often the case with hard-wooded subjects, be they slow or fast growers. When the cuttings are rooted, which they will be in a few weeks if put in at the commencement of the year, at once move them into 3-inch or 4-inch pots, according to their strength and the amount of roots they have made; replace them in the stove, and encourage growth by the use of the syringe in the afternoons, pinching out the points of the shoots so far as is necessary to lay the foundation for the future specimen, the shape of which should now be determined on. For decorative purposes, under almost all circumstances, a pyramidal form looks the best, and is the most useful; but it should not be too regular in the outline. This can be secured by allowing a reasonable amount of freedom to the lateral branches, and in not stopping them all one length, which will give them the intolerably formal appearance so objectionable in a plant grown for the effect produced by beauty of leaf and habit of growth in place of flowers. The centre shoot should be tied up to a neat stick, and stopped only so far as to prevent its running away with too much of the sap, the certain consequence of which is to leave the plant deficient of branches near the base. In this the grower must be left to judge of the requirements of each individual plant—some, as in the case of those of similar habit, having a greater disposition than others to grow upright or spread horizontally, as the case may be. By mid-summer, if all goes well, the pots will be full of roots, and another shift should be given into pots 3 inches larger, again returning them to the stove, or any house or pit where they will receive a moderate amount of heat and moisture. They will also be benefited by a little shade in bright weather. Syringe, as hitherto, once a day, which will not only assist growth, but tend to preserve them clear from insects. Keep them growing through the autumn, and if, before the end of the year, they require additional root-room, they should have it, as the object is to get the plants on in size as quickly as possible. There is no necessity to give rest during the winter; if growth were stopped in that way there would be considerable loss of time. With some plants, rest, even in the first year of their separate existence after being struck from a cutting, is more or less necessary; with others like that now under consideration it is not required, con-

tinued growth not having the slightest tendency to weaken the constitution if not pushed too far; consequently, if the pots they are in are full of roots, move them into others 4 inches or 6 inches larger, according to the strength of the plants, and keep them growing through the winter. Attend regularly, as they increase in size, to keeping the leading shoot in an upright position, and stop any lateral shoots that threaten to make more than their share of growth. The points of the shoots should also be so far pinched out generally as to cause the plants to form sufficiently close full growth; again shade slightly when bright weather comes. By midsummer examine the pots to see if they are becoming filled with roots, which, by this time, they ought to have in plenty, and, if it is required, move them on into larger; whichever is used, peat or loam, all through the several pottings, see that it contains plenty of fibre. Soil that is of a close heavy nature, even when a quantity of sand is added, is not fit for any plant intended to have its roots always kept in a confined space, neither will plants that are placed in such make near the progress that they will in fibrous soils. By the middle of September the plants may be hardened off a little by keeping them cooler, and dispensing with shade; and through the autumn do not keep them in a night temperature of more than 50°, nor less than 45°; for it must be borne in mind that, although the plant is all but hardy—if not ultimately found to be quite so—the growth has all been made in heat, and that the plants would not bear the first comparatively low temperature to which they were submitted immediately after a summer's growth in heat. It is a plant that naturally requires a great deal of water, and is in no way injured by receiving it in abundance at the root when in active growth and if the soil be filled with roots; but through the winter, when at rest, it will neither require nor bear to have much. On the other hand, like all evergreens, the soil in which it grows must not be allowed to get too dry, or the leaves will fall, and an injury to the plants be inflicted which a season's growth can alone repair; whilst, at the same time, the strength of the roots will be correspondingly exhausted. It should now be considered what size the plants are required—whether for moderate-sized or large specimens; and whether it is desirable, in the latter case, to develop them as quickly as possible; if so, they should, after a couple or three months' rest, be again placed where they will receive more heat, and be potted and grown on as before; or a portion of them may be so treated, and the rest put under a slower treatment by allowing them greenhouse room throughout the summer, giving them also such additional root-space as they need. They will make very beautiful, neat-sized conservatory decorative plants, for mixing with other fine-foliage subjects or flowering plants. In the conservatory it will be thoroughly at home, merely requiring to have its wants supplied with water, and additional root-room as the pots get too small. If it ever gets thin of leaves, and the branches look bare, they may be shortened back moderately in the spring before it begins to grow; and, if kept for a time in a little closer atmosphere, and growth be encouraged by syringing overhead, it will break freely, and soon form good fresh foliage. It is not subject to insects, but green fly will live on the points of the shoots; and if the insect is allowed to establish itself on the young leaves, it will cripple and disfigure them. Red spider will also live upon it, but, from the nature of its leaves, it is well able to bear the constant use of the syringe in the summer season, and this pest can have little chance of gaining a footing. Scale, both brown and white, will live on it. The former can be kept down by the use of the sponge; but, as regards the white species of this insect, prevention is much better than cure, and this can be managed by never allowing them to come in contact with anything affected with the pest. If once the plants get infested with it, there would be no chance of its complete destruction except cutting back into the bare hard wood, and dressing with insecticide sufficiently strong to destroy the insect, which would take a stronger application to kill it than the leaves of the Eurya will bear. This plant might be grown as a standard in the manner and for the purpose that the Sweet Bay is used. The immense demand for plants of this description, for standing out in the summer season on terraces and similar places, may be easily understood by the prices they fetch. No plant with which I am acquainted is so likely to make a fitting companion as a standard for the Bay as this Eurya; its handsome glossy foliage, still further increased in beauty by being variegated, could not fail to render it attractive so grown. Undoubtedly it would take time to get it up to the required size; but so it does with the Bay or even Portugal Laurel when grown for this purpose. The plants would require to be so treated as to form a clear stem of the requisite height by removing all side shoots until the desired height was attained; after which the plants would simply need keeping in shape by pinching out the points of any shoots that were overgrowing the rest, so as to regulate the formation of a head, and removing any side breaks

that might make their appearance; but with these I should not apprehend much trouble. The treatment in other respects as to general cultivation would be the same as above advised when they were intended for indoor decoration; and in the winter season the plants could be placed in a Vinery at rest, or any similar place where room was available. The plant is benefited when making active growth by the use of manure-water; as the pots or tubs it would ultimately occupy got filled with roots, it could for many years be kept in a growing condition by assisting it in such manner during the summer season.

T. BAINES.

SUB-TROPICAL PLANTS IN WINTER.

MUCH as these have assisted in relieving the monotony of the bedding-out system, I believe they have not as yet reached the summit of their popularity; for the majority of them are of very easy culture, and possess the great merit of being readily increased from seed; and, being of very rapid growth, they only require the protection of glass for a short period before they are fit to rank with the most beautiful objects in the garden. But it is not so much their effect during the summer as their value after their outdoor season is over that induces me to plead for their extended cultivation. One of the uses that I have found them eminently fitted for is the decoration of ball-rooms, saloons, and entrance-halls, or wherever a mass of foliage may be desired. *Acanthus latifolius* produces an excellent effect under these circumstances, its freshness of colour and bold outline making it a formidable antagonist to many of our permanent stove-plants. *Abutilons*, both plain-leaved and variegated, are also thoroughly adapted to such purposes, as well as *Ricinus*, *Solanums*, and *Wigandias*; and, as a graceful rival to the Ferns, *Acacia lophantha* is exquisite by daylight, but is scarcely so effective by night, as its leaves close up; whilst the *Centaureas*, as silvery edging plants in contrast with *Echeverias*, show out to perfection. For furnishing single vases or as table plants *Chamaepeuce Cassabonæ* and *diacantha* can scarcely be excelled in beauty of appearance under strong artificial light by the choicest of stove inmates, and they have the great advantage of not being so susceptible to injury from the great variations of temperature that often occur in crowded assemblies. Where plants of a more permanent character are employed, as Palms, tree Ferns, *Phormiums*, &c., the varieties suitable for the purpose are unlimited; the only additional care required being that the plants should be plunged in pots during summer, and lifted before any injury occurs to foliage from frost or storms. A cool Vinery suits them admirably, as the partial shade of the Vines is beneficial at first, for they will lose some roots in removal. A liberal allowance of water and a slight syringing overhead will quickly and thoroughly establish them, and they will well repay any labour bestowed on them as a surplus stock of foliage ready for any sudden emergency, besides often doing duty as substitutes for plants that the owners would not like to risk out of their regular quarters during the season when decorative plants are most in request in many country mansions.

J. GROOM.

SOWING AND GROWING AMARYLLIDS.

IN reply to your correspondent's query (see p. 82) as to the best time for sowing *Amaryllis* seed, I have to state that I have been successful in rearing seedlings sown at various periods of the season. Generally speaking, the seed is ripe in August, and may be sown at once. If this be done, the seedlings will come up very freely in the course of eight weeks, and only require to be kept growing during winter in mild heat. What the grower has to guard against is thrips and red spider, both dangerous enemies to the health of *Amaryllids*. It is better to keep the plants in a mild than in a heated atmosphere, as it is well known that an over-heated atmosphere generates quantities of these marauders, and they are not very easily kept down. The shortest time I have been able to get bulbs from seed capable of flowering is three years and a few months. In four years' time from sowing, the bulbs ought to be strong enough to produce flower scapes. To accomplish this, however, there must be no time lost in quickening growth. It is better to give the seedlings a run of root growth in a bed rather than cramp them in pots. Pot culture of seedlings is slow work, too slow for the eager cultivator; hence I would strongly recommend them to be planted out after the fashion of nursery rows in some low heated pit. The heat does not require to be great, only a degree or two in advance of greenhouse temperature. This attended to, and the seedlings kept growing, they will soon come away and swell up to bulbs of fair size. Then they must have their period of rest like all bulbs—I ought to say, like all herbaceous bulbs. The evergreen bulbs, such as *Vallota*, for instance, require constant attention with the watering-pot. Bulbs of the *Amaryllis* or *Hippeastrum* proper require a good drying from

September to January, as a rule, although there are exceptions. I find, for instance, that the beautiful white *A. marginata grandiflora* flowers best in autumn and grows in winter, something after the fashion of those charming and brilliant Cape bulbs, the *Nerines*, whereas *Marginata venusta* and *Marginata conspicua* take after the ordinary run of the breed. Beautiful as some of these well-known sorts are, they are now completely eclipsed by some of the gorgeous seedlings of more recent times. I hope to be able to show a collection of them in the course of a few months at South Kensington or some such place, where the public at large may have an opportunity of seeing them.

JAMES ANDERSON.

Meadowbank Nursery, Uddingston.

SPOTTED TRUMPET-LEAF INSECTS.

At a meeting of the American Association for the Advancement of Science, held at Hartford in August last, the following paper, "On the Insects associated with the Spotted Trumpet-leaf (*Sarracenia variolaris*)," was read by Mr. Chas. V. Riley, of St. Louis, Missouri. The insect-catching powers of those curious plants, the Flytraps (*Dionæa*), the Sun-dews (*Drosera*), and the Trumpet-leaves (*Sarracenia*), have always attracted the attention of the curious; but renewed interest has been awakened in them on account of the interesting experiments and observations on their structure, habit, and function, that have lately been recorded, and especially by the summing-up of these observations in some charming papers by Professor Asa Gray, which recently appeared in "The Nation" and the "New York Tribune" under the title of "Insectivorous Plants." Through the courtesy of Dr. J. H. Mellichamp, of Bluffton, and of H. W. Ravenel, of Aiken, South Carolina, who have sent me abundant material, I am able to submit the following notes of an entomological nature on the Spotted Trumpet-leaf (*Sarracenia variolaris*), which must henceforth rank with the plants of the other genera mentioned as a consummate insect-catcher and devourer. The leaf of *Sarracenia* is, briefly, a trumpet-shaped tube, with an arched lid, covering, more or less completely, the mouth. The inner surface, from the mouth to about mid-way down the funnel, is covered with a compact decurved pubescence, which is perfectly smooth and velvety to the touch, especially as the finger passes downward. From mid-way it is beset with retrorse bristles, which gradually increase in size till within a short distance of the bottom, where they suddenly cease, and the surface is smooth. There are also similar bristles under the lid. Running up the front or ventral side of the trumpet is a broad wing with a hardened border, parting at the top, and extending around the rim. Along this border, as Dr. Mellichamp discovered, but especially for a short distance inside the mouth, and less conspicuously inside the lid, there exude drops of a sweetened viscid fluid, which, as the leaf matures, is replaced by a white, papery, tasteless, or but slightly sweetened sediment or efflorescence; while, at the smooth bottom of the pitcher, is secreted a limpid fluid possessing toxic or inebriating qualities. The insects which meet their death in this fluid are numerous, and of all orders. Ants are the principal victims, and the acidulous properties which their decomposing bodies give to the liquid doubtless render it all the more potent as a solvent. Scarcely any other Hymenoptera are found in the rotting mass; and it is an interesting fact that Dr. Mellichamp never found the little nectar-loving bee or other Mellifera about the plants. On one occasion only have I found in the pitcher the recognisable remains of a *Bombus*, and on one occasion only has he found the honey-bee captured. Species belonging to all the other orders are captured; and among the larger species that I have most commonly met with, which, from the toughness of their chitinous integument, resist disorganisation and remain recognisable, may be mentioned *Asaphes memnonius* and *Euryomia melancholica* among Coleoptera, *Pentatoma lugens* and *Orsilochus variabilis* var. *complicatus* among Heteroptera; while katydids, locusts, crickets, cockroaches, flies, moths, and even butterflies, and some Arachnida and Myriopoda, in a more or less irreconisable condition, frequently help to swell the unsavoury mass. But while these insects are decoyed and macerated, in order, as we may naturally infer, to help support the destroyer, there are, nevertheless, two species which are proof against its siren influences, and which, in turn, oblige it, either directly or indirectly, to support them.

The *Sarracenia* Moth.

The first is *Xanthoptera semicrocea* (Guen.) a little glossy moth, which may be popularly called the *Sarracenia* moth. It is strikingly marked with grey-black and straw-yellow, the colours being sharply separated across the shoulders and the middle of the front wings. This little moth walks with perfect impunity over the inner surface of the pitcher, which proves so treacherous to so many other insects. It is frequently found in pairs within the pitchers soon after these

open, in the early part of the season or about the end of April. The female lays her eggs singly, near the mouth of the pitcher, and the young larva, from the moment of hatching, spins for itself a carpet of silk and very soon closes up the mouth by drawing the rims together and covering them with a delicate, gossamer-like web, which effectually debars all small outside intruders. It then frets the leaf within, commencing under the hood and feeding downwards on the cellular tissue, leaving only the epidermis. As it proceeds, the lower part of the pitcher above the putrescent insect collection becomes packed with ochreous excrementitious droppings, and by the time the worm has attained its full size the pitcher above these droppings generally collapses. This worm when fully grown is beautifully banded transversely with white and purple or lake-red, which Dr. Mellichamp poetically likens in brightness to the Tyrian dye. It is

XANTHOPTERA SEMICROCEA.—a, egg, enlarged, the natural size indicated at side; b, c, larva, back and side views; d, chrysalis; e, moth, normal form, with wings expanded; f, pale variety, with wings closed.

furthermore characterised by rows of tubercles, which are especially prominent on the four larger legless joints. It is a half-looper, having but six prolegs, and keeps up, in travelling, a constant restless, wavering motion of the head and thoracic joints, recalling paralysis agitans. The chrysalis is formed in a very slight cocoon, usually just above or within the packed excrement. The species, kindly determined by Mr. A. R. Grote, was many years ago figured by Abbot, who found it feeding on *Sarracenia variolaris*, in Georgia. Guenée's descriptions were made from these figures, for which reason I have made some descriptive notes from the living material. The species feeds alike on *S. variolaris* and *S. flava*, and there are at least two broods each year, the first brood of larvæ being found during the early part of May, the second towards the end of June, and disappearing with the dying of the leaves.

The *Sarracenia* Flesh Fly.

The second species is a still more invariable living accompaniment of both kinds of *Sarracenia* mentioned. By the time the whitish efflorescence shows around the mouth of the pitcher, the moist and macerated insect remains at the bottom will be found to contain almost invariably a single whitish, legless grub or "gentle," about as large round as a goosequill, tapering to the retractile head, which is furnished with two curved, black, sharp hooks; truncated and concave at the posterior end of the body. This worm riots in the putrid insect remains, and when fed upon them to repletion bores through the leaf just above the petiole and burrows into the ground. Here it contracts to the pupa state, and in a few days

SARCOPHAGA SARRACENIÆ.—a, larva; b, pupa; c, fly, the hair-lines showing average natural lengths; d, enlarged head and first joint of larva, showing curved hooks, lower lip (g), and prothoracic spiracles; e, end of body of same, showing stigmata (f) and prolegs and vent; h, tarsal claws of fly with protecting pads; i, antenna of same. All enlarged.

issues as a large two-winged fly, which I have described (*loc. cit.*) as *Sarcophaga sarraceniae*—the *Sarracenia* flesh-fly. The immense prolificacy of the flesh-flies, and the fact that the young are hatched in the ovaries of the parent before they are deposited by her on tainted meat and other decomposing or strong-smelling substances have long been known to entomologists, as has also the rapid development of the species.

The viviparous habit among the Muscidae is far more common than is generally supposed, and I have even known it to occur with the common house-fly which normally lays eggs. It is also possessed by some Cestrinæ, as I have shown in treating of *Cestrus ovis*, the sheep bot-fly. But the propensity of the larvæ for killing one another, and their ability to adapt themselves to different conditions of food-supply are not sufficiently appreciated. I have long since known, from extensive rearing of parasitic Tachinadæ, that when, as is often the case, a half dozen or more eggs are fastened to some caterpillar victim only large enough to nourish one to maturity, they all hatch and commence upon their common prey, but that the weaker eventually succumb to the strongest and oldest one which finds the juices of his less fortunate brethren as much to his taste as those of the victimised caterpillar. Or, again,

that where the food supply is limited in quantity, as it often is, and must be with insects whose larvæ are parasitic or sarcophagous, such larvæ have a far greater power of adapting themselves to the conditions in which they find themselves placed, than have herbivorous species under like circumstances. Both these characteristics are strongly illustrated in *Sarcophaga sarraceniarum*. Several larvæ, and often upwards of a dozen, are generally dropped by the parent fly, within the pitcher: yet a fratricidal warfare is waged until usually but one matures, even where there appears macerated food enough for several. And if the *Xanthoptera* larva closes up the mouth of the pitcher ere a sufficient supply of insects has been captured to nourish it properly, this *Sarcophaga* larva will nevertheless undergo its transformation though it sometimes has not strength enough to bore its way out, and the diminutive fly escapes from the puparium, only to find itself a prisoner unless deliverance comes in the rupture or perforation of the pitcher by the moth larva or by other means. This rupturing of the pitcher does not unfrequently take place, for Dr. Mellichamp writes under date of June 27, as follows: "Most old leaves now examined—I might almost say all—instead of being bored, seem ripped or torn, as if by violence, apparently from without. You see occasionally shreds of the leaf hanging. Surely the legless larva of *Sarcophaga* cannot do this!" What then—the toads, frogs, or crawfish abounding in these moist pine lands? or rather is not the fat maggot the occasion of the visits of the quail which lately I have observed here? These two insects are the only species of any size that can invade the death-dealing trap with impunity while the leaf is in full vigour, and the only other species which seem at home in the leaf is a minute pale mite belonging, apparently, to *Holothyrus* in the *Gamasidæ*, and which may quite commonly be found crawling within the pitcher; and a small *Lepidopterous* leaf-miner, which I have not succeeded in rearing. There must, however, be a fifth species, which effectually braves the dangers of the bottom of the pit, for the pupa of *Sarcophaga* is sometimes crowded with a little *Chalcid* parasite, the parent of which must have sought her victim while it was rioting there as larva. No other insect, so far as we now know, can crawl up the slippery belt—all tumble into the tube and there meet their death.

Means of Escape.

Certain questions very naturally present themselves here:—First, What gives the flesh-fly more secure foothold on the slippery pubescence than the common house-fly exhibits? Second, What enables the larva of the flesh-fly to withstand the solvent property of the fluid which destroys so many other insects? Third, What gives the *Sarracenia* moth and its larva security? I can only offer in answer the following suggestions:—The last joint of the tarsus of the common house-fly has two moveable sharp-pointed claws and a pair of pads or pulvilli. These pads were formerly supposed to operate as suckers, and all sorts of sensational accounts of this wonderful sucker have been given by popular writers, who forgot that there are any number of minute insects having no such tarsal apparatus, which are equally indifferent to the laws of gravitation so far as walking on smooth upright surfaces, or on the ceiling, is concerned. In reality, these pads are thickly beset on the lower surface with short hairs, most of which terminate in a minute expansion kept continually moist by an exuding fluid—a sort of perspiration. Take the soft human hand, moistened by perspiration or other means, and draw it, with slight pressure, first over a piece of glass or other highly-polished surface, and then over something that has a rougher surface, such as a planed board, a papered wall, or a velvety fabric, and you will experience much greater adhesion to the smoother objects, and may understand the important part which these moist pads play in the locomotion of the fly. They also act, in part, like the cushions of a cat's paw in protecting and preventing abrasion of the claws, which are very useful on the rougher surfaces, where the pads are less serviceable. Now, compared with *Musca domestica*, the claws of *Sarcophaga sarraceniarum* are much the longer and stronger, and the pads much the larger, presenting three or four times the surface. These differences are, I think, sufficient to explain the fact that while the common fly walks with slippery and unsteady gait on the smooth pubescence (the retrorse nature of this pubescence sufficiently explaining the downward tendency of the movement), its sarcophagous congener manages to get a more secure footing; for not only does the latter present a larger adhesive surface, but the longer claws are more likely to reach beyond the pubescence and the bristles, and fasten to the cellular tissue of the leaf beyond. Moreover, *Sarcophaga* is more thickly beset with stiff spinous bristles than *Musca*, and Dr. Mellichamp says that when disturbed it buzzes violently about, just as if an animated sheep-bur had fallen into the tube—not apt to go down, because it will hitch and stick, and finally, by main force, it generally emerges, but sometimes also succumbs. In answer to the second question, I can only say that there is nothing exceptional in the power of the larva to withstand the solvent quality

of the fluid; it is, on the contrary, in accordance with the facts known of many species of *Muscidæ* and *Estridæ*, some of which, like the well-known horse-bot, revel in a bath of chyme, while others are at ease in the intestinal heat of other warm-blooded animals. It is also well known that they will often live for hours in strong liquids, such as alcohol and turpentine. In answer to the third question, the moth is doubtless assisted in walking within the tube by the spine and spurs on the legs which it, in common with most other moths possesses; the tarsi in *Xanthoptera* being armed with spines, and the spurs being quite long, and in *semicrocea* usually shod at tip with a corneous point. Its larva overcomes the treacherous surface by either carpeting it with silk, or destroying it. To one accustomed to seek the why and wherefore of things, the enquiry very naturally arises as to whether *Xanthoptera* and *Sarcophaga* play any necessary or important rôle in the economy of *Sarracenia*. Speaking of the *Sarcophaga larvæ*, Mr. Ravenel asks, "May he not do some service to *Sarracenia* as *Pronuba* does to *Yucca*?" And if so, may not all this structure for the destruction of insects be primarily for his benefit? Can he be merely an intruder, sharing the store of provision which the plant, by ingenious contrivance, has secured for itself, or is he a welcome inmate and profitable tenant? Self-fertilisation does not take place in *Sarracenia*, and the possibility that the bristly flesh-fly aids in the important act of pollination, lends interest to the facts. No one has witnessed with greater pleasure than myself the impulse which Darwin has of late years given to such enquiries; but we should be cautious lest the speculative spirit impair our judgments, or our ability to read the simple lesson of the facts. My own conclusions summed up are:—1. There is no reason to doubt, but every reason to believe, since the observations of Dr. Mellichamp, that *Sarracenia* is a truly insectivorous plant, and that by its secretions and structure it is eminently fitted to capture its prey. 2. That those insects most easily digested (if I may use the term) and most useful to the plant are principally ants and small flies, which are lured to their graves by the honeyed path, and that most of the larger insects, which are not attracted by sweets, get in by accident, and fall victims to the peculiar mechanical structure of the leaf. 3. That the only benefit to the plant is from the liquid manure resulting from the putrescent captured insects. [Mr. Ravenel, in making a transverse section near the base of the young leaf, noticed large tubular cells passing down through the petiole into the root, and much of the liquid manure may possibly pass through these into the root stalk.] 4. That *Sarcophaga* is a mere intruder, the larva existing on and sharing the food obtained by the plant, and the fly attracted thither by the strong odour, as it is to all putrescent animal matter or to other plants, like *Stapelia variegata*, which give forth a similar odour. There is nothing to prove that it has anything to do with pollination, and the only insect that Dr. Mellichamp has observed about the flowers with any frequency is a *Cetoniid* beetle—the *Euryomia melancholica*—which, with other species of its genus, is commonly found on many different flowers. 5. That *Xanthoptera* has no other connection with the plant than that of a destroyer, though its great injury is done after the leaf has performed its most important functions. Almost every plant has its peculiar insect enemy, and *Sarracenia*, with all its dangers to insect life generally, is no exception to the rule. 6. That neither the moth nor the fly has any structure peculiar to them that enables them to brave the dangers of the plant, beyond what many other allied species possess.

Russian Bast Mats.—About 400,000 mats are annually exported from the port of Archangel alone, and large quantities also reach us by way of the Baltic and Black Sea. The exportation in this way amounts to about a million and a half of mats a-year. The home consumption cannot be given in exact figures, but there is no doubt that it greatly exceeds the quantity exported. The manufacture of mats is mainly a domestic industry. The peasants employ their spare time in the maceration and separation of the liber of the Lime tree into slips, and in plaiting the latter into mats, which are purchased wholesale by commissionaires. Lime trees from twenty-five years of age are fit for decortication for the manufacture of mats, and in localities where the Lime is not sufficiently plentiful to supply the wants of the inhabitants in the way of mats and shoes it is replaced by the bark of the Willow and Birch. Indeed, in the Government of Kostroma, one of the principal centres of this industry, the Lime forests are already all destroyed, so that the materials to carry it on have to be procured from other districts, for the inhabitants are loth to give up an occupation which has been continued for centuries. The bark is removed in spring or early in summer, about three weeks being devoted to this part of the work. The value of the mats exported to Europe in 1871 amounted to nearly £50,000.

TREES AND SHRUBS.

THE SCOTTISH PINE.

A WRITER in a weekly contemporary says:—"The Scottish Pine appears to thrive in deep valleys, and to grow equally well on the mountain side. Finer examples of these trees may be found on almost any English estate than their native woods affords." The writer of this paragraph can only be very imperfectly acquainted with the Scottish Pine in its native habitats. He cannot have traversed Glenmore, and looked upon the remnant of the noble trees that once occupied that celebrated glen. Their glory has departed; but a feeling of awe and regret passes through the mind as one looks upon the skeletons of the mighty dead which have been torn and worn by the tempests of centuries. Where are their equals to be seen, living or dead, on any estate in England? I would advise the writer referred to go to Badenoch, and see "the giants," "whose statures reach the sky," to use the words of the late Professor Wilson, who had seen more of Highland scenery than most men of his day. I am sure that his opinions will undergo some modification. A resident on the banks of the Spey in olden times, who had the opportunity of seeing the timber rafts floated down that rapid river to the sea, would have smiled at seeing such absurd statements made. The mighty tenants of Abernethy had reached the sea before my days, but I have often stood on the banks and watched the remnant of those noble trees that were floated down the river from time to time. Sixteen square miles of the forest Rothmurchus has gone to the ground. The axe has been busy in many a magnificent Scottish forest, but a mass of timber still remains, as anyone may see who traverses the course of the Dee, the Spey, and the Findhorn, besides many a strath and glen whose dark recesses are made still more sombre by the trees of the native Pine. Pure air and drainage it must have to bring it to that perfection in which it may yet be seen while clinging to the almost naked rocks in many of the highland glens. In the valleys where the air is moist, the bole of the trees are sometimes grey with lichens; but higher up, where the air is more rarified, their smooth trunks are often of that deep flesh colour that gives them such a striking appearance at a distance. That there are many fine specimens of the Scotch Fir in the parks and plantations of England, and in the Lowlands of Scotland, I do not deny; "but people who have seen it in its native climate and soil, and who judge of it from the wretched specimens which are suffocated in English plantations, with their roots in heavy and eternally wet clays, may well call it a wretched tree, but when amongst its own Highland Heather, and standing freely in its native knoll of dry gravel, or thinly-covered rock, over which it spreads its network of roots, its appearance is far different." It is astonishing how rapidly the Pine shoots up to the size of a tree in many parts of Scotland, but it requires generations to bring it to perfection, and it will require time to solve the problem whether the immense planted Pine woods in Scotland will ever equal in size of timber and quality the ancient forests of that country. The writer referred to remarks that "It would be a prudent and proper course for the Government to insist on the preservation of a few acres of the best trees in each district as seed parents for future forests;" but he does not say whether naturally-planted trees ought to be preferred to artificially-planted trees. He does, however, refer to miniature and decrepid specimens, left on account of their inferiority, which, he says, are prone to produce cones more abundantly, and become the parent stocks of future forests, thus perpetuating degeneracy. I am not in a position to say whether the nurserymen in the north of Scotland, that raise such enormous numbers of seedling Pines, gather their seeds from such trees or not; but should this be really the case, it would be well for planters and for those nurserymen that purchase quantities of one-year-old seedlings from northern growers to enquire into the matter. That stunted Pine trees bear cones freely cannot be questioned; but that they are more prolific than fine old full-grown trees, no one really acquainted with the Pine would maintain. This is not a question for Government intervention, but for landed proprietors and those interested in the commercial value of timber trees. A rather singular thing regarding the propagation of the Pine by seed came under my own observation some years back. I noticed a number of rocks carrying what appeared to be Potatoes in their bills to a bare rocky knoll, then carefully burying them in the earth. On examination, instead of Potatoes, I found them to be Fir cones. For what purpose the rocks buried them there I am unable to say, but only conjecture that they placed them there as a provision for winter use during heavy snows. The spot became, in a short time, covered with fine young Firs, and is now densely covered with trees. In traversing the highland glens and extensive woodlands of the north of Scotland my own impression was that a great natural renovation was taking place. I have noticed, on some of the highest mountains,

Fir trees embedded in the peat. How many ages have passed away since those trees reared their heads aloft I am unable to say, but ever since they were laid low by fire or some great convulsion of Nature, the soil where they grew has been undergoing a natural preparation to receive their successors. The rapid growth of the Fir, where it has been extensively planted in the north, is a proof of what I state. It is impossible to conceive the extent of the ancient Scotch forests until one carefully examines the mountains and hills now bare and treeless. Where the relics of the trees that once flourished upon them lies concealed in the soil or peat, and it is very evident that if these extensive wastes are to be clothed with verdure, the hand of man must do it. "Be aye sticking in a tree, Jock?" was the Laird of Dumbiedyke's advice to his son, and the advice should not be lost upon the present generation of Scotchmen, who, by adding to the Fir woods of their country, enhance the value of the cultivated land, and add also to the beauty of the district. J. T.

SPINDLE TREES.

A large proportion of these species are hardy enough for cultivation in Britain, and are now frequently met with either in the open shrubbery or on walls, for which some of the more tender of the evergreen sorts, from their free growth and beautiful foliage, are admirably adapted. All the species have small and inconspicuous flowers, with little beauty to commend them to the attention of cultivators; but this defect is amply compensated for by their fine foliage, handsome habits of growth, and the bright showy fruit which some of the sorts produce in abundance in autumn and winter. They grow well in almost every variety of soil, but are most luxuriant in such as are rich in vegetable matter, such as peat or decayed leaves, and, as a rule, they prefer open sunny situations to exposed ones, particularly the evergreen sorts. They all thrive well in the vicinity of the sea, particularly the deciduous sorts. The following are among the most distinct and desirable of the species and varieties at present in cultivation:

Euonymus europæus (the common Spindle tree).—This is indigenous to England, as well as to a wide area on the Continent of Europe, and is a deciduous bushy tree, varying in height from 10 to 25 feet. The leaves are of a warm green colour, changing as they decay to a reddish tint. When bruised they have a disagreeable odour. Its small greenish-white flowers expand in May, and are followed almost always by an abundant crop of fruit, produced in bright pink capsules, which opening up in the autumn, reveal the orange-coloured sac which envelops the seeds, producing a strikingly beautiful effect. This tree is deservedly popular in shrubbery borders and in ornamental plantations. It always looks best when trained up for a few feet from the ground to a single stem, the upper branches being allowed free scope, or at least only pruned sufficiently to give it a trim tidy appearance. It is scarcely necessary to add that it is one of the hardiest of the group, and that it succeeds well near the sea. Of several varieties, the most interesting are the white fruited kind, which differs from the species in producing white instead of pink capsules; the variety with scarlet leaves; and *nanus* or *pumilis*, a neat little plant, very bushy, and one which never grows higher than about 2 feet, and it is admirably suited for a rock-garden, or any situation where a compact dwarf-plant is desirable.

E. latifolius (the Broad-leaved Spindle tree).—This is another European species, found wild in the south of France and in some parts of Germany, and is a deciduous tree of from 10 to 20 feet high. The bark on the young wood is of a reddish-green colour. The leaves are bright shining green, and much larger than those of the common *Euonymus*. The flowers, which expand in June, are of a purplish-white; the capsules large, and deep red, contrasting, as they open, most effectively with the bright orange sacs or arils, with which the seed is enveloped. It is quite hardy, but thrives best in moderate shelter, and forms an exceedingly ornamental tree, well fitted for a lawn or small park, as well as for associating with evergreens in the mixed shrubbery border.

E. americanus (the American Spindle tree).—This is a small deciduous, or, in mild winters and sheltered situations, sub-evergreen shrub, of about 6 feet in height, found wild over a wide area in Canada and the United States. It has an erect habit of growth, with numerous long slender branches covered with a smooth light green bark. The leaves are of a deep shining green. The flowers expand in June, and are succeeded by rough warted brilliant crimson capsules, which, in its native habitats are so showy and abundant that it is popularly called the Burning Bush. In this country it is generally cultivated as a wall plant, and as such it is very ornamental. It succeeds best on the shady side, and prefers a moist rather than a dry porous soil.

E. angustifolius (the Narrow-leaved Spindle tree).—This is also indigenous to North America, and is found in similar localities as

the preceding. It is a recumbent twiggy evergreen or sub-evergreen shrub of about 4 feet in height. It has long wiry branches, abundantly clothed with remarkably narrow oblong leaves, of a deep green colour in summer, changing in autumn to a dull red tint. The flowers are very small, of a greenish-white colour, followed by red fruit capsules, which are, however, neither produced in sufficient quantity here, nor conspicuous enough individually, to give the plant a feature. It is, nevertheless, a very distinct and interesting shrub for a low wall, and has a pretty effect on a rockery, growing freely in shady sheltered aspects, and in damp heavy soils.

E. japonicus (the Japan Spindle tree).—This is an evergreen species of from 4 to 6 feet in height. It has an erect bushy habit of growth, the branches being long and slender, and clothed with numerous ovate-formed leaves of a dark glossy-green colour. Though hardy, and of free growth, in sheltered districts it seldom or never produces flowers in this country—a defect, however, which is amply compensated for by its very attractive foliage. Few evergreens thrive better near the sea than this does; and either it, or some of its varieties, are frequently met with on the west and south coasts of England, and west coast of Scotland, growing in the greatest luxuriance, and forming handsome specimen shrubs on lawns and shrubberies. In the inland districts it is liable to suffer from very severe frosts, and can only be depended upon when enjoying the shelter of a wall or in favoured situations in the open ground. During recent years a considerable number of distinct varieties have been sent home from time to time from gardens in Japan; several of these, and particularly the following variegated forms, are already established favourites. All the sorts thrive best in warm sunny exposures, and in rich well-drained soils. The kind called *argenteus variegatus* has leaves clothed with silver; *aureus variegatus*, leaves blotched with bright gold; *ovatus aureus*, leaves margined with deep golden-yellow; *latifolius argenteus* and *latifolius aureus*, leaves with white and yellow variegations respectively; and *radicans variegatus*, a creeping-stemmed variety, seldom extending to a greater length than 2 feet; its leaves are freely variegated with white; it is very hardy, and useful for planting as an edging to flower-beds or front of shrubbery borders. On rockeries or low walls it has a pretty effect; and as it forms adventitious roots on the young shoots, similar to those of the Ivy, it requires little trouble in the way of tying or nailing to keep it to the wall or other support.—“The Gardener.”

Bad Writing and Illegible Signatures.—As the Parliamentary Session is approaching will you permit a suffering M.P. to make known a real grievance in which I feel sure that you will sympathise with me? I allude to the increasing illegibility of handwriting and the extraordinary pains that are taken by some people to disguise their signatures. I happen to have a large correspondence, and in other respects am not an idle man; but, if I were, I should still find occupation in the daily attempt to decipher some of the letters I receive. If the writers only knew what an irresistible temptation there is to throw their hieroglyphics into the waste-paper basket unread, they would be a little more careful to make their handwriting decently plain and legible. How can they expect that in the pressure of business, and with perhaps a dozen letters to read which are brought by a single post, a member of Parliament can find time to sit down and puzzle out the meaning of his correspondent as patiently as if he were trying to decipher the inscription on the Moabitish stone, or some new variation of the cuneiform character. But it is chiefly with the signature that fantastic tricks are played. Often do I gaze hopelessly at the cabalistic sign which does duty for that office, and try every ingenious device to enable me to divine who it is that addresses me. I take my family into council and submit the curious symbol to my wife and daughters, who sometimes are able to solve the riddle and rescue me from my dilemma, but who are often as helpless as myself. I cannot always have Mr. Netherclift or Mr. Chabot at my elbow, and I have been driven to the expedient of cutting off the signature and posting it on the envelope which contains my reply. I thus throw upon my noble friend, the Postmaster-General, the responsibility of finding out the name of my correspondent. There is one secretary of a company in London—yes, a secretary—who signs his name in a way which is unintelligible and ridiculous. Now, why should this be? It has been said that language was given to conceal our thoughts, and some people seem to think that signatures are meant to hide our names. A drunken spider crawling out of an ink-bottle would really give as much information as the flourishes and dashes and rigmarole caricatures which they intend to stand for letters. I wish I could except the fair sex altogether from the charge of caprice in signatures, but I cannot, although in this respect they do not sin so much as men. Pray, Sir, say something to induce people to write plainly, clearly, and legibly, and you will confer a boon upon others besides an M.P.—“Times.”

GARDENING FOR THE WEEK.

Flower Garden and Pleasure Grounds.

LAWNS seldom look fresher or more beautiful than at present, and for some time to come all that will be necessary in order to keep them in good condition will be an occasional sweeping and rolling. Mossy lawns are sometimes objected to, and where such is the case the present is a favourable time for endeavouring to eradicate the Moss, an operation which may be accomplished by means of a sharp-toothed iron rake; with this drag the Moss to the surface, when it should be cleared carefully off, and a portion of lawn Grass-seed (which may be procured ready mixed from any seedsman) should be sown carefully over the cleared surface. After that a slight surface dressing of any finely-sifted rich soil should be applied, and well stirred in with an iron rake, and the whole should then be repeatedly rolled. Under trees, however, or in any other situations where Grass does not grow well, the Moss should not be disturbed; on the contrary, it should rather be encouraged. Continue to frequently roll gravel walks and drives in order to keep them in good condition, and occasionally refresh the surfaces of beds of spring-flowering plants, which will now begin to be attractive. Prepare beds in which to plant *Ranunculuses* and *Double Anemones*, and push on as rapidly as possible the propagation of summer bedding plants, keeping store pots containing *Ageratums*, *Bouvardias*, *Verbenas*, *Lobelias*, *Petunias*, *Coleuses*, *Iresines*, and similar plants in a gentle bottom-heat, in order to induce them to furnish abundance of strong healthy cuttings. When sufficient of the latter have been secured, the autumn-struck cuttings may be thrown away, as those struck in spring are generally to be preferred, unless it be in the case of such plants as the various kinds of bedding *Pelargoniums* and *Calceolarias*. A very brisk heat is necessary to induce the *Alternantheras*, more particularly *A. amoena*, to furnish cuttings at an early period in the spring. But unless it be in cases where a very large stock of these plants is required, a high temperature need not as yet be applied to them, as when growth, in their case, does commence, they quickly produce abundance of cuttings which will strike root in the course of a few days; and in their case, as in that of *Verbenas* and similar bedding plants, potting-off is unnecessary, as they may with advantage be allowed to remain in the cutting pots until required for planting out in the beds; and thus a very considerable amount of labour, as well as of pots and space, may be saved. In adopting this plan, however, it is advisable to use pots about 8 inches in diameter, and to let them be well drained, say to about one-fourth or fifth of their depth. Over this spread a thin layer of chopped moss or fibre, in order to prevent the soil from mixing with the drainage, and then pass some moderately rich light soil through a half-inch sieve, and with a sieve of, say, one-quarter inch mesh, sift from this the finer particles, and with the portion which will not pass through the meshes fill the pots to within two inches of the rim. Then with a compost, consisting of about equal parts well-decayed leaf soil finely sifted, and sharp river or silver sand, fill up the remaining 2 inches, and into this insert the cuttings, not too deeply. Each pot will contain from two to three dozen cuttings, more or less, according to their size. Place them in a mild bottom-heat, in a somewhat close moist atmosphere, and frequently sprinkle them until they are fairly rooted, when they may be removed to cooler quarters. Plants thus prepared must be shaken out of their pots at planting time, when their roots will be found to have laid firm hold of the portion of rough soil which was placed under the sandy compost, and this ought to be allowed to adhere to them as much as possible. They should then be planted at once somewhat thickly in the prepared soil of the beds, with a small setting-stick; and, should the weather prove dry, a little extra care as regards watering may be necessary. Plants, thus treated, will generally be found to succeed equally well, or better, than the same sorts turned out of small pots.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Orchids.

A rise of 5° in Orchid-houses this month will be beneficial to all re-potted plants. We must now pot and top-dress such plants as require that attention, and as a great deal depends on the freshness of the soil in securing a healthy growth, they must not be over potted. We seldom see healthy plants of *Epidendrum vitellinum*; yet, when it is well grown, this is one of the most useful of Orchids. It lasts many weeks in bloom, and its colour is so distinct as to contrast strikingly with that of its associates. It should have a temperature in the autumn and winter months from 50° to 55°, and should never be allowed to get dry at the root. On bright days its growths should be syringed. *Oncidium macranthum* will be growing freely this month, and great care will be required in watering to prevent the water coming in contact with the young growth, otherwise the flower-spike will be injured. This kind will grow in a temperature as low as 40° or 45°. *Odontoglossum Hallii* does well

in the same temperature, and will produce flower-spikes 3 to 4 feet in length, with twenty flowers on a spike. When seen like this, it is one of the most noble of our cool Orchids, and if it be possible to get it, should be sought after by importers. The same degree of temperature suits *O. nebulosum*, which should never be allowed to get dry at the root. When well grown and flowered this kind is very useful to arrange with others. *Calanthe Veitchii* and *C. vestita* should not be potted till they have made sufficient growth to render the young roots discernible. Two parts of strong loam, one part of old cow-manure, and one part of coarse sand and charcoal should then be used, and the pots placed in a temperature of 65° to 70°. Pot the favourite *Masdevallias* in equal parts of peat and Sphagnum Moss and a double quantity of coarse sand and charcoal. Always keep it well supplied with water, and maintain a temperature of 45° to 55°. *Pleiones* will require watering more freely this month, and must be syringed on bright days. *Dendrobiums* and *Cypripediums* that are making growth should have the warmest part of the house they are placed in, and must be syringed on bright days. Water should be used sparingly till they have established plenty of roots. Continue to keep *Disa grandiflora* plentifully supplied with water. *Coelogyne cristata* will now be in its beauty, as will also the section of *Cattleyas* to which *Trianae* belongs, as well as *Lycaste Skinneri* and its white variety, *Pilumna fragrans*, *Oncidium bicallosum*, *Dendrobium nobile*, *D. infundibulum*, *Laelia superbiens*, *Cypripedium villosum*, *Odontoglossum Bluntii*, *O. pulchellum*, *O. Hallii*, *Vanda suava*, *Phalænopsis grandiflora*, &c.—E. CULLEY.

Fern-house.

The first or second week in this month is a good time to go over Ferns, re-potting such as require it and top-dressing others, using good peat with a liberal admixture of coal cinders broken to the size of acorns; these are more effectual in keeping the soil open than potshreds. All tree Ferns grow quickest when their stems are syringed once or twice a day during their season of growth, but if they are required for the decoration of halls or for exhibition at times, it is better not to syringe, as the roots that are encouraged by syringing receive a check, in which case they are likely to be ruined. Large *Gleichenias* may be divided, but not into small pieces; plants, say in 18 or 20-inch pots, may be divided into two or four. Of all Ferns for mixing with flowers, either in vases or in bouquets, *Gleichenia Speluncæ* stands pre-eminent. It will last for a week in water. It is not advisable to cut small plants; but, when well managed, all the varieties are quick growers, and when the plants get large they will bear cutting in moderation with impunity. In large Ferneries, where most things are planted out, the selection and planting require judgment, in order that suitable varieties may occupy the positions for which they are best adapted, studying well what proportions each individual plant is likely to attain, quite as much as present effect, otherwise, instead of a satisfactory arrangement of these most elegant of vegetable forms, a confused jumble will be the result. Another important consideration is to have the plants free from insects, such as mealy bug or scale, otherwise endless labour will be entailed. Such kinds as *Adiantum Farleyense* and the *Gymnogrammas* require more heat during the winter than the majority of the occupants of the Fern-house, and it is better to remove such kinds for the winter to a slightly warmer house. The Fern-house during winter ought not to be kept at more than 50° night temperature, with a rise of 5° during the day. It is a mistake to use too much heat in the Fern-house, as it makes its inmates so tender that such as are required for cutting flag so as to be almost useless, and if the plants are required for decoration elsewhere they suffer as well as become unsightly. As soon as growth commences supply them liberally with water.

Hard-wooded Plants.

Bring all tying and training to a close as soon as possible, and prepare for potting all plants that require a shift towards the end of the month. Commence first with hard-wooded Heaths; half specimens and full-grown plants that require more root-room ought to be moved into pots 4 inches larger than those they at present occupy, for it is not desirable to re-pot these plants oftener than can be helped. See that the ball in all cases is sufficiently moistened before re-potting, so that watering may be avoided as long as possible after the operation. All newly-potted plants should be set at one end of the house, and do not admit more air at the end than can be avoided for three weeks or a month, keeping, at the same time, the stage damped with the syringe. Where there is not the convenience of separate houses for Heaths and for other kinds of hard-wooded plants, but where all have to be grown together, the Heaths ought, as far as possible, to be kept at one end, at which, except after recent potting, admit more air. After the potting of the Heaths is finished, commence with the other hard-wooded stock, using peat a little more

fibrous, or what is known among plant-growers as softer, than that which is used for the Heaths; but operating, in other respects, as recommended for those plants. Any additions that are intended to be made to the young stock of hard-wooded plants ought to be made forthwith, and all that require it potted on, giving to them pots 2 or 3 inches larger, according to the condition of the roots of each individual plant. All the plants, young and old, ought to have the potting completed as expeditiously as possible after it is once commenced, as then the whole can have what extra attention they require.

Indoor Fruit Department.

Vines.—Wireworms often prove destructive to the young Vines, as they devour the tender rootlets as soon as they are emitted, and frequently also any young shoots that are on the eyes at the time. It is difficult to trap them, but in the case of small pots, when the soil gets heated to 80° they generally come to the surface, when they may be removed and destroyed. If the soil used is in the shape of turves, or in boxes or beds, slices of Carrots placed here and there underneath the surface will be found to form good traps for them. The Carrots should be examined every morning and replaced until the whole are caught. If a small stake is pushed into every slice, it will form a handle by which the Carrot slices may be raised and examined. Wireworms will not remain long in company with ants, which attack and kill them. Keep the surface soil about young Vines free from weeds, and do not allow the surface to become pasty—on the contrary, keep it constantly free and open. If not already done, remove the weakest shoot from such “cut backs” as have pushed two shoots. As soon as the one left has reached a height of 18 inches, lift the pot out of the plunging material and set it on a dry surface in the Vinery, or in some pit in which a temperature of 70° is maintained. If retained in bottom-heat after this stage has been reached, they receive more harm than good. Although I do not approve of the system where any house of young Vines is intended to be an early one from the first, they should be planted about the second or third week in February, in order that they may be started into growth in time to be early ripened for a corresponding start the next and following seasons. I need hardly say that only Vines belonging to the Hamburg section should be chosen for such a purpose.

Pines.—Such plants in the first started batch of Queens as did not fruit well have been kept somewhat drier than the others during the last few weeks. A good watering should, therefore, now be given them; and, in all probability, they will show fruit in a short time. If not, do not neglect them, as they may be of good service in autumn. Other varieties may fruit while growing freely, but Queens do so reluctantly. A check to their growth is always necessary, in order to induce them to fruit, which appears before growth in the foliage begins. Admit fresh air to young plants on all favourable occasions, as it is very desirable to have their foliage partly hardened when the shortest days are past, and before lifting them into other pots has taken place. If it is necessary to make preparations for giving the young plants more room, old stumps from which the fruit has been cut may be removed. Suckers should, however, be carefully taken off valuable kinds, securing along with them as many as possible of such young roots as will be found clinging round the old stem. Such suckers will not suffer in the least if laid in by the heels amongst the plunging material until the Pines generally are shifted when they may be potted and plunged along with the others.—J. MUIR.

The Early Peach-house.—The fruit will now be set in the earliest house, and syringings morning and evening will be required in favourable weather. Attention should likewise be bestowed on the thinning of the fruit where they are set thickly, but this rarely happens when forcing commences so early. The disbudding of the shoots is a process best performed by taking off only a few of the strongest at different times, so as not to give a check to the roots. The temperature at night may be maintained at about 60°, with a rise to 70° by day, and by sunheat 6° or 8° higher. Green fly will begin to make its appearance, and the infected shoots must be picked off; but fumigation with tobacco will have to be resorted to at the last. The old system of fumigating hot-houses with the operator inside the house is now obsolete, and it was a cruel infliction on young gardeners and others who could not stand tobacco smoke. Some of the new patented fumigators are very efficient for the purpose; for, by making a hole in each door of the house for introducing their nozzles from the outside, the house can be soon quite filled with smoke, and kept so for any required time.

Fig-house.—Figs should be kept well watered and syringed with the night temperature at about 60°. When the young shoots have grown to the length of four or five joints, the terminal buds must be picked out to encourage the formation of a second crop.

Cherry-house.—The temperature must be kept low, from 40° to 50°, with plenty of air given on favourable occasions, until the fruit is set. After that they will bear more heat, with frequent syringings overhead, till the fruit colours.

Strawberries.—Occasional batches will want to be introduced into the pits or forcing-houses according to the consumption required. When sufficient fruit has been set on a truss, the rest of the blossoms should be picked off to strengthen the fruit left on. Liquid manure, if used twice a week, will help the fruit to swell, but it must be discontinued before the fruit begins to colour.

Cucumber and Melon-house or Pit.—The sun will now be more powerful, and, therefore, more favourable for forcing Cucumbers and Melons. A night temperature of from 60° to 65° is not too much, and the day temperature, by sunheat, may range to 80°. Maintain plenty of moisture on the pathways and plants, but beware of scalding draughts of steam by dashing water on the pipes or flues. Another sowing of seed may be made to supply the general stock of plants, for gardeners always find a good many friends begging Cucumber plants in March and April to plant in their frames.

Tomatoes.—This excellent fruit, if sown in the beginning of February and pushed on in heat, will ripen good crops in pots as early as May or June. The dwarf Orangefield is the best for this purpose. The Trophy and General Grant do not fruit so freely, and are later in bearing.

Kitchen Garden.

Sow a few seeds of Red Cabbage to succeed those sown in autumn. In some establishments Red Cabbages are used for other purposes besides pickling, and, therefore, it may be advisable to have a few coming in at various times to meet any demand that may arise. Plant early Potatoes on a warm dry border, where there is a good depth of rich soil. If they were placed in shallow trays as advised some time back, they will now be in good condition for planting; all growths, except one strong shoot, should be removed. In planting, either open trenches with the spade or draw rather deep drills with a long bladed hoe shaped like a carpenter's adze (a very useful tool for heavy soils), scatter a little thoroughly decayed manure along the bottom of the drills, place the Potato sets on it, and cover about 4 inches deep. Early Potatoes may be planted much closer to each other than later crops, and some pains should be taken to limit the growth so as to allow only one shoot to spring from each tuber; this alone will make a week's difference in the period of ripening, and make the crop more uniform in size. No crop pays better for liberal treatment, and where there is a scarcity of other manure, superphosphates may be profitably used for pushing on the growth and increasing the yield; about 7 or 8 lbs. per rod may be applied, sown in the drills with the Potatoes at planting time. Plant out now the main crop of Shallots and Garlic; only a small quantity of the latter is required in English establishments, but Shallots are largely used. Select a light dry situation on one of the quarters that have been laid up rough during the winter; burnt earth or charred refuse makes a good top-dressing to be mixed with the surface. Plant the bulbs in rows at a distance from each other of 1 foot, and 6 inches apart in the rows. In heavy land, avoid deep planting; simply press the base of the bulbs into the earth, and have ready a few bushels of light rich soil, in which burnt earth predominates, and place a handful in a small mound over each bulb. This will tend to secure them in the earth, and, being of an elastic nature, will offer no obstacle to their swelling to a good size, as the light coverings will crumble down to the natural level as the season advances. Make a further sowing of Peas; Dickson's First and Best is a very prolific kind, coming in a few days later than Ringleader. Huntingdonian may be sown at the same time for succession; this is the best of the Champion of England type I have yet seen. Long-pod and Green Windsor Beans may also be planted; the latter variety is generally the most esteemed, on account of its beautiful green colour, for the main crop. Beans sown last month in boxes under glass must be thoroughly hardened off by removing the lights whenever the weather is favourable. The same remark also applies to Peas that are now waiting in cold frames; transplanting Peas and Beans in this way has a tendency to induce early maturity, which, with the earliest crop, is of more importance than heavy and continuous bearings, as in most places the second sowing follows so closely on the heels of the first as to render that unnecessary. Sow the round-leaved Spinach between the rows of Peas every two or three weeks, and frequently stir the soil amongst the autumn-sown crop to encourage its growth, as there is usually in most places a large demand for this wholesome vegetable. Parsley may be sown any time this month, either in beds or as an edging to borders; sow in shallow drills thinly, and cover with light rich soil. In covering small seeds any little trouble incurred in this way will be amply repaid by a plentiful crop.—E. HOBDAV.

THE ELEPHANT HAWK MOTH.

THIS moth (*Chœrocampa elpenor*) is tolerably common throughout England. The larvæ feed naturally on Willow Herb (*Epilobium*) and on Bedstraw (*Galium*), but in gardens it confines itself chiefly to plants belonging to the natural order *Onagraceæ*, which are probably its proper food plants; for though Bedstraw is said to be one of them, and though I am aware, from personal observation, that it will feed and do well on this kind of plant, still it is usually found upon those of the same order as Willow Herb. It is very frequently met with on the *Fuchsia gracilis*. These caterpillars were discovered in this neighbourhood (South Wales) last year, in some numbers, on Fraser's Evening Primrose (*Oenothera Fraseri*), a plant brought here from North America in 1811, and no doubt it may be found on the common Evening Primrose (*Oenothera biennis*), and on plants of the same order, such as Enchanter's Nightshade (*Circæa Lutetiana*). The Elephant Hawk moth is a very remarkable caterpillar in appearance; it is 3 inches long, or more, the anterior segments being much smaller than the posterior ones, and the head smaller than the second segment. The colour is either brown or green, and is variously mottled and marked with black, the marks along the back forming an almost uninterrupted dorsal line; on each side of the fore part of the body are two dark round marks, in the upper part of each of which is a white kidney-shaped mark. From its large size and strange appearance it is sure to attract the eye of the most casual observer. It occurs in such very limited numbers that it is not likely to do much damage to our gardens, unless it attacks some choice plants of the *Oenothera* or *Fuchsia* tribe. The moth flies in June, and is a very beautiful object; the fore wings are much pointed, their colour is olive-green, tinted and shaded with pink; the hind wings are black at the base, shading off to the same delicate pink at the hind margin, which is edged with white; the body is of the same olive-green colour as the fore wings, and is tinged and marked with pink. OWEN WILSON.

ACREAGE OF ORCHARDS, MARKET GARDENS, &c.

ACCORDING to a Blue Book return, just published, the following is the acreage under orchards, market gardens, nursery grounds, and woods in each county in England, Scotland, and Wales, in 1874:

COUNTIES.	ORCHARDS, &c. Acreage of arable or Grass lands, but used also for fruit trees of any kind.	MARKET GARDENS. Land used by market gardeners for growth of vegetables and other garden produce.	NURSERY GROUNDS. Land used by nurserymen for growing trees, shrubs, &c.	WOODS. Coppices, or plantations, excepting gorse land and garden shrubberies.

THE FERNS OF BRISBANE.*

By Mr. ROBERT GRIEVE.

EVERY riverside within twenty miles of Brisbane is skirted with Ferns to a breadth varying from a few yards to a few miles. Dense, moist, gloomy, the nocturnal mosquito here hums its war-song at noonday. Here around us, closely packed, are many fantastic forms of plant life—the large parasitic Fig-trees of various kinds, the Red Cedar (*Cedrela Toona*), the gigantic Nettle (*Urtica gigas*), and the Seaforthia Palm. At our feet are various growths analogous to the Maranta and the Caladium. Above our heads are festoons of creepers, while at every step our progress is impeded by some Wait-a-bit Thorn, or the Vines or Lianes that bind the whole together. Such are the localities which produce some of our finest Ferns. First of all is the tree Fern (*Alsophila*), which rises to the height of 30 or 40 feet. I only know of one species, although hardly at the skirts of the wood is its congener, the *Dicksonia dubia*. Of the *Pteris* genus we have four species. Around us is the *Pteris tremula* with its polished ebony shafts. Then comes the still larger and most graceful plant, the *Pteris vespertilionis*, rising to a height of 10 feet, and delicate in the texture of its leaflets as a sensitive plant. The two other *Pteris* are not found in the same locality; we find them in the open country and elsewhere. They are the inevitable *aquilina*, and the more rare *Pteris longifolia*. As we painfully force our way through the forest, we tread on the two interesting little Ferns, the *Pellaea-paradoxa* and *falcata*. On that rotting tree-stump hard by twine in brotherly love the two small *Niphoboli*—

* Read before the Edinburgh Botanical Society.

confluens and rupestris. We next come upon a plant, the only one of its genus with us, the *Atlantodia australis*. Proceeding on over the rich loose leaf mould that we unsettle with our feet as we walk along, we come upon a most graceful Fern, well calculated to be an ornament to every conservatory, the *Nephrolepis exaltata*. Another *Nephrolepis*, the *obliterata*, may be seen adhering to some rocks outside the forest, and insinuating its polished roots here and there among the loose stones, pure of any soil. Outside the forest, and close beside it on its stony habitat, is that very curious plant, the *Drynaria diversifolia*. These are withered Oak leaves adhering to that Fern, one would say in passing. But they are not. They are the first produced pinnatifid unfertile fronds, always desiccated, of that tall feathery *Polypodium*, to which they adhere. Try to drag the plant from its rocky matrix. Impossible. To obtain it, you must take the rock with it. But let us return to the forest. Every here and there, in a moist hollow of a dead tree, may be seen the *Nephrodium molle*, like an immense Prince of Wales's feather; and, still more common, and of a darker green, is the *Nephrodium decompositum*, of which there are several varieties. We have, besides, two other swamp-growing kinds of this plant, viz., *Nephrodiums*—*unetum* and *propinquum*. These, however, do not seek the shade. Allied to this genus, I may mention here the *Lastrea coriacea*. In the depth of the scrub, often growing in solid masses of many yards' extent, we find the dark green *Asplenium attenuatum*, conspicuous for its proliferous reproduction. There are several varieties of this Fern, some of them, perhaps, sufficiently distinct to deserve a separate name at some future time. In the meantime, I take leave to show the Society a Fern I myself discovered, which bears some superficial resemblance to the *Asplenium*, but is, perhaps, more closely related to the *Doodias*. I have shown specimens of each for comparison. A very much finer and larger species of *Asplenium* than the last, and one of our choicest Ferns, is the *fulcatum*. High over our heads, it grows in the hollows of the surrounding trees, from which it throws out its bunches of long dark green crescents; and it is generally obtained with some difficulty. So also is that other beautiful epiphyte, an *Asplenium* also, as it is sometimes called, the *Neottopteris australis*, a grand Fern, very much like what I believe is called the Bird-nest Fern by gardeners. It attains a size at which each leaf may measure 8 feet. Talking of epiphytes brings me to the *Davallia pyxidata*, the Hare's-foot Fern, a beautiful species that is common enough in our British conservatories. All these epiphytes grow in similar situations, mostly high up in the ragged branch hollows of the largest trees, sometimes at 20 feet, sometimes at 200 feet; and even at that distance such Ferns as the *Neottopteris* and the *Platyneria* loom out grandly through the gloom. The most beautiful of them all is, without doubt, the *Platynerium alciorne grande*. I was privileged at a late meeting of your Society to hear read a letter from Moulmein, in which this Fern was described as, I think, extending to 15 feet in breadth. I am glad to be able to some extent to corroborate this statement, having frequently seen it covering as much as 100 square feet, or about 12 feet by 8. Its general appearance is too well known to require description. We have also another species of *Platynerium*, which may not be so familiar to British botanists, viz., the *Alciorne longifolium*. It is a much smaller plant than its magnificent neighbour, and has a perfectly distinct fructification. In the grande, the fructification crosses the whole of the broad disc-like fronds devoted to that purpose, whereas the *longifolium* only bears seed upon the tips of its comparatively attenuated leaves. The *Polypodium tenellum* is a creeping Fern, it makes its way like the Ivy or the *Convolvulus* up the trunks of the trees, and adheres to its support by numerous fibres in the manner of the Ivy. It is the last of the forest Ferns that I shall name, and in doing so generally, I would have it to be understood that the nomenclature is given with diffidence. Passing out from the shade of the forest, we cross the broad meadows. Every here and there a gigantic Gum tree or Iron-bark (both *Eucalypti*) intercepts the vertical rays of the sun. We see around us the ubiquitous *Pteris aquilina*, and mixed with it is the similar but fairer Fern, the *Polypodium rugulosum*. The *Dicksonia dubia* also grows in compact and tall masses hard by. We also find the *Doodia aspera* on the stony ground. We have three *Doodias*, the *aspera*, *media*, and *caudata*, the latter two species seeking a moister habitat. By the shade of these rocks grow two pretty little Ferns, light in form but dark in colour, resembling one another, and yet distinct, the *Cheilanthes Sieberi* and the *Notholaena distans*. But let us get out of the sun over the broken banks of that streamlet not far off, and see what we can find. There, in all its beauty is the lightest, airiest, most herbaceous of all Ferns, the *Lindsaea microphylla*, not in single stalks, but in great bunches of transparent vegetation. In the shape of its leaf it recalls the *Sphenopteris affinis* of the coal measures. The other *Lindsæas* are growing near, in all five species, specimens of which are on the table

—*Lindsæa microphylla*, *L. Fraseri*, *L. linearis*, *L. trifida*, *L. heterophylla*. They form altogether a group matchless for grace and delicacy. In connection with this family, and true of all Ferns, the remark occurs to me of how unchangeably exact in soil, moisture, and exposure are the natural habitats of all Ferns. Thus, those *Lindsæas* grow all on poor, sandy soil, yet each requires its own particular degree of poverty, and each insists on its own proper quantum of moisture; so that, given the locality, the exact plant to be found there can at once be predicated. Talking of the pure sandy soil, reminds me of two very unique Ferns, which love the inhospitable sand, *Schizæa dichotoma* and *Schizæa bifida*. Their resemblance to the Grasses causes them frequently to be passed over almost unnoticed. By the shelving banks of this stream, or among its undergrowths, may be found all our three *Adianta*—fair, fairer, fairest—*Adiantum formosum*, *A. hispidulum*, and *A. assimile* (so called from its close proximity to the Maiden-hair of Europe). The Maiden-hair is partly shaded from the light by another Fern, the *Blechnum cartilagineum*, and nearly in the stream itself is the other *Blechnum*, *B. striatum*. This is a swamp Fern. It only remains for me now to name three or four other swamp Ferns, and I have done. Conspicuous among them for size and beauty is the magnificent *Todia barbata*. It has a large central crown of veneration enclosed in fifty fronds, each standing 8 or 10 feet high, and rich in its solid masses of purple seed. Then, not inferior in size, if somewhat in grace, is the large *Chrysodium anreum*, which only grows on the banks of tidal streams. A Fern that we must not forget is the *Lygodium microphyllum*. It is a creeper, and a plant of it may be seen trailing through the reeds and water plants for many yards, leaving everywhere a gay festoon as it moves along. A specimen of it is on the table. It superficially resembles the *Tropæolum canariense*, but is still more light and delicate. Lastly, we have our three *Gleichenias*, with their simple rudimentary seeds at the back of each frond, ready to drop off at a touch—*Gleichenia dicarpa*, *G. microphylla*, and *G. flabellata*. They are wiry and incompressible, but eminently graceful and light. With these I shall conclude this list of our Brisbane Ferns.

ECONOMISING CUT FLOWERS.

FLOWERS are so scarce at present that it may seem useless to talk of saving them and time enough to begin in spring; but, on the other hand, there ought to be no waste of flowers when they are so valuable, and forced flowers are very suitable for the use I wish to recommend them for. I observe a great waste of cut flowers—after being worn they are thrown away. Now, if those worn in the evening were cast into the bath or jugs of water, they would be refreshed, and many of them fit for use by morning again; and those worn in the early part of the day would be revived for evening. Many flowers and scented foliage give off much perfume when floated thus in water, and the result is a morning or evening bath of "sweet waters," more pleasant than any scented soap concocted by the perfumer. Living in a garden, and surrounded with flowers, the plan I recommend is daily practised. Because one can have any quantity or variety of flowers, it is no reason at all why they should be wasted, and the fresh perfume of the water is a cheap and pleasant luxury. Try the following next spring:—*Daphne Cneorum* and Sweet Briar; Yellow Azalea and Sweet Briar; forced Roses and Gardenias; Jonquils, Lily of the Valley, and Mignonette (forced); sweet-scented Geraniums, of sorts, and Pinks; Lilac and Narcissus poeticus; Syringa (Philadelphus); all Tea, summer (Cabbage and Portland), and Scotch Roses. No Attar of Roses comes up to these last double varieties; Heliotrope and Clove Carnations; Lavender, Aloysia citriodora, and other sweet smelling herbs; Jessamine and Lemon Thyme. Orchids would be delicious, I am sure, and one flower of certain varieties would perfume a large bath, but I have no experience of these. Stocks, Wallflowers, Honeysuckles, Lily of the Valley, and Mignonette, do not give off so much perfume as one would expect; why, I do not know. When forced, the two last are more powerful than when flowering in their natural state. Perhaps for true invigorating refreshment marine plants and sea water is the most delightful bath, but one may not always live by the sea, or on a rocky coast essential for the growth of sea weeds.

Wardie Lodge, Edinburgh.

F. J. HOPE.

Alonsoa myrtifolia (Roetzl).—The height of this plant is from 2 to 2½ feet; it is of a very vigorous growth, and exceedingly floriferous. The individual flowers are larger far than in any other species of this genus, and of a more intense scarlet than those of *Alonsoa linifolia*. It makes a very good pot plant, but, by reason of its strong growing character, it is principally adapted for large beds in the open ground, for which, on account of the showiness of its flowers, it will be of great service.—W. THOMPSON, Ipswich.

NOTES AND QUESTIONS.

[THE following notes and questions came to hand, or were answered too late for insertion in their several departments.]

Trichomanes radicans.—This, though frozen into a mass of ice which encrusted and buried it many inches deep for many weeks, thawed out as fresh and fine as anyone could desire.—J. BACKHOUSE, York.

The Virginian Creeper in Shrubberies.—In various nooks in the pleasure ground here we have the small-leaved variety of this plant festooned from tree to tree with wire. It has a pleasing effect in autumn when the leaves are changing colour.—T. P. T., Wicklow.

Mistletoe on Mistletoe.—Dr. Masters showed recently, at the Scientific Committee of the Royal Horticultural Society, specimens from Mr. Corderoy, of Didcot, in which young seedling Mistletoes had grown upon the parent plant.

Varnish for White Woods.—Dissolve three pounds of bleached shellac in one gallon of spirits of wine; strain, and add a gallon and a half more of spirit. If the shellac is pure and white, this will make a beautifully clear covering for white wooden articles.

Josephine de Malines Pear.—I have this fine late Pear now in excellent condition from a bush tree. It is one of the best Pears with which I am acquainted, and is especially valuable now, when other dessert fruits are getting scarce.—J. C. T. W.

Hardiness of *Sarracenia purpurea* and *Darlingtonia californica*.—These have stood the late severe frost here without any artificial protection, and only partially covered with snow, even when the thermometer registered under 2° at no great distance off.—J. BACKHOUSE, York.

Cotoneaster microphylla at Killruddery.—This answers admirably when planted and trained as a covering for old pollard and broken down trunks of trees. There is one here that is draping a fine old stump of an Oak some 30 feet high which is just made to form one of the most picturesque objects on the grounds.—T. P. T.

Large Conifers at Dropmore.—The largest Deodar at Dropmore (planted in 1834) is said now to be 65 feet high and 52 feet through; the trunk, at 3 feet from the ground, girthing 9 feet 7 inches. The finest specimen of the Douglas Fir (raised from seed sown about 1827 or 1828) is now 106 feet high, and the height of the famous Dropmore *Araucaria imbricata* is now 69 feet.

Trees and Shrubs at Killruddery.—Some time since a fine old upright Cedar blew down. I had occasion to remove the bottom part of it, and, measuring it 30 feet from the ground, found it to be 2 feet 9 inches in diameter. I did not pass the tape round the root or buttress, but it was of enormous dimensions. Bay and Common Laurel are of immense size in stem, the latter in some places forming quite a forest of timber.—T. P. T.

Orchids Without Orchid-houses.—I have a large plant of *Phajus grandifolius* growing here amongst a mixed collection, which, though it only receives ordinary attention, is bearing ten splendid spikes of bloom. It has been subjected to a temperature during the winter of only 50°, and will now be removed to the cooler air of the statue gallery, where last year it sustained no apparent injury.—T. P. T.

Home-raised Pot Vines.—Your correspondent "Vitis" (see p. 74) is fortunate in being able to supply not only his own establishment with such excellent home-raised pot Vines as those he describes, but also the trade. I have seen many an attempt made to grow pot Vines in large establishments, and that under the superintendence of efficient gardeners, too, but in every case the result has been anything but satisfactory. If failures were brought to light as successes are, they would, I apprehend, be greatly in excess of the latter, and I am confident that bought Vines are, in the end, not only the cheapest, but the most satisfactory.—W. LAURIE, Alva.

Lilium Thunbergianum Wilsoni.—This was figured in the "Florist" from a plant in the possession of G. F. Wilson, Esq. It is very distinct from all the Japanese Lilies known in England. The ground colour of the flower is of a reddish-orange colour, the central portion of each segment being of a golden-yellow, and the whole surface nearly to the edge marked over with dark coloured dots, similar to those of the Tiger Lily. The flower indeed may be described as having the general form and character of *L. bulbiferum*, the colour and spotting of *tigrinum*, and the golden band of *auratum*. It is one of the most beautiful hardy Lilies we have seen.

Spring Flowering Bulbs.—The following Crocuses, and other bulbs, are now in flower in Mr. Barr's grounds at Tooting, viz., *Crocus aureus*, rich golden-yellow, the flowers preceding the foliage; *C. susianus* (reticulatus) golden-yellow, exterior brownish-black; *C. Oliverii* (Aucherii, Chripanthus), rich orange-yellow; *C. stellaris*, rich golden-yellow, exterior striped blackish-brown; *C. luteus*, the large yellow of the garden; *C. sulphureus striatus*, sulphur-yellow, exterior striped black; *C. Imperati*, violet, exterior fawn, striped black; *C. Sieberii*, violet-purple; *C. versicolor* var. *Albertini*, pale purple with deeper stripes; *C. hadriaticus*, white, base of flower blue; *C. biflorus* of Parkinson, white, exterior striped purple; *Leucojum vernum*, white, tipped green; *Scilla sibirica*, intense blue; *Galanthus nivalis*, white; *G. plicatus*, the Crimean Snowdrop, white; *G. Imperati*, white; *Anemone blanda*, blue; *Eranthis hyemalis*, the Winter Aconite, yellow; *Triteleia uniflora* var. *conspicua*, white tinged porcelain; *T. uniflora*, var. *lilacea*, lilac-porcelain.—P.

Sowing Primrose Seed.—Mr. Frank Miles advises the sowing of Primrose seed as soon as it is ripe, but intimates that in his experience Primrose seed germinates in a very irregular manner, some of the seed starting very late indeed. This, I think, is the inevitable result of sowing the seed as soon as gathered, as some of it is then matured whilst a portion may be very imperfectly so, and if sown at once it is probable that a part may start soon enough to produce plants that will entirely stifle seeds that germinate later. I prefer to hold the seed over until the spring, keeping it thoroughly dry, and then sowing it about the month of February in shallow pans or boxes placed in a cool house. Under these conditions the seed germinates with more certainty, and the seedling plants soon get strong enough to be transplanted into the open air where they make good blooming crowns through the summer, and will assuredly flower in the ensuing spring. They would not accomplish more if the seed were sown the previous summer, whilst much trouble is avoided. I am pleased to find that Mr. Miles is largely cultivating the Primrose. It will prove to him a source of great pleasure. I have a large bed of strong seedlings just coming into bloom, and there is a promise of many very beautiful plants amongst them.—A. D., Bedford.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ON THE GEOLOGICAL ASPECTS OF ROCK-WORK.

WHEN rock-work has to be erected for horticultural purposes it will always be found that success will be attained just in the proportion in which some broad principles, based on a study of Nature's own work of that kind, have been followed. Every lover of Nature must have envied her power of adorning rough stony nooks by means of a few of the commonest plants; a Fern or two and a little Moss convert a few weather-beaten rocks into objects of beauty which it has often been attempted to imitate—usually without success. Yet success is attainable in almost every case if sufficient attention be only paid to the rules which, it will be seen, are as sacred to the physical agents which model our scenery as they ought to be to every landscape gardener. It is a trite observation to say that what pleases us in Nature is the perfect fitness of things which pervades all her belongings. The most rugged, abrupt, and even grotesque rock-masses, when untouched by man, never repel us by a sense of incongruity; they may be pleasing or awful as the case may be, but we feel no hint of their being out of place. Who, on the other hand, has not seen a lovely view marred by some unintelligent human hand, whether its work took the form of a quarry, a statue, or a vase? The secret of the difference lies in the word "weather-beaten:" rain, the chief rock-sculptor, working uniformly, slowly, and gently, leaves to each stone, which it is fashioning, its proper character, models it according to its peculiarities of composition and structure—in short, uses it fitly; while men with the most artistic pretensions, and armed with ruthless tools, too often misuse their materials, engaged, as they are in their ignorance, in the hopeless task of making "silk purses out of sows' ears." The first great rule which it behoves constructors of rock-work to look to is one very easily followed and constantly broken, it is, that "your rockery should be characteristic of the part of the country in which it stands." That is to say, use chalk at Brighton and sandstone at Tunbridge, granite on Dartmoor, and trap near Edinburgh. This seems obvious enough, but the experience of every one must include cases where the reverse rule appears to have been acted on. Some "artists" have even carried their Philistinism in this respect so far, that the more they have succeeded in giving to their rock-work the appearance of a miscellaneous collection of mineralogical specimens from all parts of the world the better have they been pleased. The familiar burnt brick of the South of England and the slag and painted coke of the northern coal districts are better than these. It is needless to point out what are the rocks suitable for rock-work in the different parts of Britain; a walk in the country will show you the rocks, and a glance at any geological map will tell you their names. The second rule, not to be departed from, is one not so easy to adhere to as the last, but quite as important, viz.:—"The form of your rockery should be that which in Nature is assumed by the particular kind of rock of which it is composed." In order to appreciate the amount of careful observation which this rule renders necessary, we must consider what are the various agencies which, together, bring about on rocks the result which geologists know by the name of "weathering." Nature's mode of making her rocks weather-beaten requires such an amount of time, that we cannot attempt to imitate her in that respect; but, if we cannot use her means, we can copy her results. Now, the weathering of a rock depends, before all things, on the structure of that rock, on its composition, and on the manner in which it is exposed to rain, frost, wind, and the atmosphere itself, which are the great weathering and rock-carving agents. On many rocks water acts mechanically only; or, to be more accurate, its power of dissolving some rocks, such as quartz, is so limited, even when, as is almost always the case, it is charged with carbonic acid, that it is inappreciable, and may, for practical purposes, be left out of the reckoning. On a great mass of quartzite rock, for instance, the effect of rain would be of this kind. It could scarcely

dissolve any of it away; but it would insinuate itself in every crevice and fissure and crack with which such hard rock abound near the surface, and thence, by the help of frost, blasts to shivers, winter after winter, layer after layer of the tough rock, just in the same manner as it blasts the water-pipes of our houses. By observation it is found that every rock affects a more or less peculiar kind of fracture, so that, bursting splinters from them, as has just been shown, the lines of fissure are not arbitrary or accidental. They, like everything else in Nature, form part of a plan. Hence, a particular class of form is the result for each rock of the purely mechanical action of the weathering agent. In the case of quartzite, for instance, the fracture is "conchoidal," shell-shaped, concave and wavy; this, on a large scale, gives rise to peaks with somewhat hollow sides, ridged with sharp surrounded edges. It may serve as an example of simple weathering on a homogeneous, hard, and practically insoluble rock. Let us see what takes place with more complex rocks of which granite may serve as a representative. This rock is made up essentially of three minerals—quartz, felspar, and mica in various proportions. Now, here, the water, with its carbonic acid, will act not only mechanically, as in the case of quartzite, but as a powerful solvent and disintegrator. The fissures in granite are large and continuous, taking the form of immense joints, which cross and re-cross each other often but not always, in a regular manner; but, besides these large lines of weakness, which affect the whole rock, there are the minute lines which separate the constituent minerals from one another. Into all these the water trickles, decomposing the granite along the joints and cracks, "widening them, and rounding off the angles of their intersections, and, ultimately, only the harder masses, or the hearts of the blocks defined by the joints, remain as solid crystalline granite; some, though a little, of the quartz is dissolved away by the water; the iron which is usually present in small quantities in granite "becomes oxidized, and weakens the rock; but it is chiefly the felspar that is decomposed by the action of carbonic acid, the alkalis are removed, and its residue is washed away in the form of fine china clay. . . . The quartz crystals remain as sand; the mica remains, but is less observable, and is partially decomposed." (Professor Rupert Jones.) It is by processes such as that just described that the many fantastic shapes assumed by granite rocks have been arrived at, whether they be those of the curious balanced "Logging stones" of Cornwall or Brittany, the bare rounded tors of Devon, or the grey sterile mountain tops of Aberdeenshire. All felspathic rocks of eruptive origin, such as porphyries, are moulded into the shapes which they now exhibit in the same way as granite, and such also is the case with those sedimentary rocks which consist, to a considerable extent, of felspar, such as many of our gritstones. In these, however, a greater uniformity of weathering is caused by the regular lines of bedding which take the place of the horizontal joints of the former class of rocks. The vertical joints are similar in both. In igneous rocks, such as basalt and greenstone, the jointing and fissuring is often of such a kind as to give rise to very striking effects, very various in their appearance, though probably closely allied in their origin. Thus, from the simple dark brown, or black trap, without apparent structure, forming shapeless masses of a rounded, somewhat unpicturesque outline, there is but one step to the bold semi-columnar escaliments of trap, which are so conspicuous in Northumberland and in many parts of Scotland; thence to the wonderful assemblages of rigid pillars of Staffa and the Giant's Causeway, with all their suggestiveness to rock-builders, the transition is shorter still; while, in many parts of the three countries, we have examples of trap weathering into a mass of many coated spheres of every size, decomposing layer by layer, with only a small core of the untouched rock in the centre of each ball. It is a noteworthy fact that basalt in this spheroidal condition weathers and decomposes much more rapidly than it does in the prismatic or columnar state. Rocks such as these, we have been considering (with the exception of the grits) have also been thrown up in a molten or pasty condition, which precluded their being subject to many of the rules which water-deposited rocks are bound by. Their structure is a great measure the result of cooling; and, although the

frequently have a bedded appearance, they are not under the rigid sway of dip and strike which in all other rocks is all-powerful in producing, or rather in preparing, the structure of a country. Indeed, in the great majority of cases, it is the advent of the eruptive rocks which has given to the sedimentary deposits their present positions, or what is technically called the "lie." Few of the latter, whether sandstones, limestones, shales, clays, or sands, are now lying in the horizontal position in which they were formed, especially in much-disturbed and dislocated Britain. Great geological operations have taken place since then, and have squeezed, tilted up, and broken these beds of rock into every shape. And it will be obvious to all that, had it not been for these great changes, the edges of these rocks could never have been brought under the influence of rivers to carve them on a large scale into hill and dale, and of rain more delicately to "weather" and ornament them. It is, therefore, very necessary to observe the dips, or general mode of lying of the beds, of any district which it is desired to make use of for rock-work purposes. The writer has seen a large rock-garden in the north of England which was laid out with great care and at vast expense, and which is spoilt by one apparently small, but fatal oversight—the dip of the beautifully-arranged rockery-blocks is westerly and strongly marked, while the dip of the real "live" rock immediately beneath is due east. Now this seems a small thing to find fault with; and it is true than an uneducated eye might be well pleased, in ignorance of the defect. But consider that to the easterly dip in that part of the country is to be attributed the shape of the hills and valleys which make its beauty; without it the fine slope on which this garden stands would not be in existence—the entire district would be altered, to say nothing of the fact that, were it not for this dip, and the vast industries which it fosters, the wealth which built the rock-garden would have been elsewhere. "Follow Nature in all things," is the only safe motto for the landscape gardener. It would be tedious, and perhaps not very useful to enumerate the different kinds of water-bedded rock which can in Britain be used for rock-work. A glance at the chief members will suffice.

Of the grits we have already spoken, and their mode of weathering is that of the entire class of sandstones, coarse and fine grained, massive and flaggy. With regard to the latter, it may be allowable to point out, for special reprobation, a mode of rock-building which seems to be gaining favour in many districts. It consists in placing a number of broken flagstones on end, and in every position relatively to one another; the result is peculiarly hideous, and resembles no possible combination of Nature's art, since the flags, at whatever angle they may be dipping, are always parallel among themselves, except in the case of the arrangement known as "false bedding," which is one not likely to be successfully imitated. Sandstones are, as a rule, peculiarly adapted for rock-work from the forms assumed by them on weathering, from their great frequency, and from the great variety of their colours. From dark brown to bright red, from red to yellow, from yellow to white, thence through every tint of grey to blue and purple, the choice of colouring is great indeed in these rocks. They are found everywhere—as hard grits in the old silurian and Cambrian districts, as great rugged crags throughout the carboniferous regions, forming the well-known old red and new red sandstones, more sparsely distributed among the oolites, but forming occasional bands of striking character among the sands and clays of the Wealdon (witness the "greys" of the Lover's Seat and other marked natural rockeries in the neighbourhood of Hastings and Tunbridge Wells), and, in the much more recent tertiaries, appearing occasionally, as in the sands of Brussels, as lines of grotesque fistulous masses running through incumbent sand, very much as flints lie in our upper chalk.

Many sandstones and grits pass gradually into more or less coarse conglomerates, that is to say, rocks formed of rolled pebbles and blocks of stones derived from other pre-existing formations. Of such conglomerations there are many examples in Britain, and they are often very suitable for rock-work, owing to the uneven weathered surface, which is the result of the different sizes of the pebbles, and occasionally of their different hardness, which causes them to be dislodged

unequally. The permian conglomerates, in many places of central England, are great additions to the natural beauty of the scenery, and have been frequently taken advantage of for the ornamentation of grounds. Under the name of limestone must be included a very large number of rocks different in texture, hardness, and general aspect, but having this in common—that they are chiefly composed of carbonate of lime. The result of this composition is that more than any other rocks are they liable to the solvent, as distinguished from the disintegrating action of water charged, as rain-water always is to some extent, with carbonic acid. This action we see displayed on a large scale in the great stalactite-lined caverns in the carboniferous limestone of the north of England, or in the sand-pipes running deep into the chalk of the south country. On a smaller scale, the effects of this dissolving power are marked on every exposed face of limestone of every age, and help to make them everywhere worthy of the attention of the rock-gardener. In some instances thin beds of hard limestone are weathered into a curious honey-combed state, the exposed parts being of a lighter colour than the inner stone; in others the face of the beds present the appearance of a clumsy balustrade of the Louis XIV. style, the interstices having been gradually eaten away by the water running down the original lines of upright joints. Sometimes the most peculiar forms are assumed in this manner by limestones, and each kind has its own special characteristic shape, to be known only by constant observation; but perhaps no rock equals the great magnesian limestone of Durham in the eccentricity or in the multiplicity of its disguises. This limestone is of a yellowish colour, and its structure is wonderfully diversified, sometimes hard and compact, sometimes friable, often concretionary and botryoidal, occurring as a mass of radiated concentric spheres of all sizes, generally crystalline, often as a distinct breccia or agglomeration of angular fragments held together by a cement of similar material. A walk along the coast of Durham, from South Shields to Roker, will show to what vagaries of weathering and denudation this extraordinary variety of conformation has given rise. The high cliffs are in places worn into deep caves; in others slender pillars of rough rock have been separated from the main mass, and stand solitary on the beach, while larger islands of rock stand out at sea, through which arches of every size and shape have been excavated. No rock can be better suited for rock-work if used judiciously, and it is moreover known that its chemical composition is such as to be very beneficial to rock-plants. These magnesian limestones are called Dolomites, and it is notable that their fantastic shapes are by no means confined to England, since no mountain-range is so remarkable for abruptness and startling variety of configuration as that in the Italian Tyrol, known as the Great Dolomites. Besides the hard old stony limestones, of which we have spoken, there are in England a number of other kinds, from the oolitic stones to the chalk, which can occasionally serve the landscape-gardener's purpose. Their appearance is too well known to need description here. In newer geological series there are frequently beds of a light porous limestone, very similar in appearance to the sinter, which is deposited by petrifying springs. In many places this is called "ragstone," and it is extremely well adapted for our purpose; this distribution is, however, very local in Britain; so that, according to our theory as to the æsthetics of rockery, they cannot be very widely used. Abroad, in tertiary districts, they are far more common, especially on the shores of the Mediterranean, both on the European and on the African side. Schists and shales may, for the purposes of rock-building, be considered together; the former being simply the hardened and altered form of the latter. Their weathered appearance, where exposed, varies very much with the angle of their dip and with the degree of crystallisation to which they have attained. Some schists are quite as crystalline as granite, and they then weather in the same manner, with this proviso, that the lines of foliation, or lamination, direct the operation. Where such beds are highly inclined, as on the south-west coast, or in Brittany, a curious appearance is often seen, which may be called the "Artichoke form," as it exactly resembles the mode of arrangement of the Artichoke leaves. At lower inclinations, schists and the harder shales do not form striking features; but, by

offering slight rocky elevations, above a more or less level ground, with distinct "craig and tail shapes" they can be made highly effective in rock-gardening where they occur naturally. This has been done with the greatest success in the Central Park, New York. The softer shales may be dismissed as rockery materials, except for the purpose of forming the lower of the two beds of rock necessary for the construction of a good waterfall or of an overhanging crag. While on the subject of waterfalls, it may be as well to remind the landscape-gardener that, with very few exceptions, the rocks forming waterfalls in Nature dip up-stream, and this holds good for great and small falls alike. The clays and sands need not detain us; where these "unrocky" materials prevail, the rock-maker is clearly entitled to do the best he can to try and imitate the rock-masses of more favoured districts. But even then he should be bound by what we will call our third rule, which flows naturally from the other two laid down above. In no case should your rockery be constructed in a manner contrary to the broad geological laws to which all rocks are subject in their natural state.

In this brief survey of a large and interesting subject, it has only been intended to suggest some points for the consideration of rock-builders, and to show that success in their art, as in every other, is to be attained only by strict and careful observation and study of Nature's own models. G. A. L.

SUNKEN BOILERS.

WHEN it is found that a stokehole that is 5 feet deep has 4 feet of water in it, which can only be kept under by constant pumping or bailing, one is naturally tempted to ask whether sunken stokeholes are absolutely necessary. As long as the weather remains very sharp and dry, the springs will be at a low ebb; but when, as has been the case during the past month, we have an immense and continuous rainfall, it changes the aspect of affairs; for, wherever water can force itself in, it will do so, to the partial extinction of fires and the discomfort of stokers. We are here on the margin of the Thames valley, and in a country that is flat and with a very sluggish fall; when, therefore, the water, as is the case now, is found within 18 inches of the surface, it is evident that something more than ordinary precautions are needed to keep it within bounds. My stokehole, when first constructed, was protected all round with a considerable thickness of clay-plugging, but it has never proved efficient; and now, for the second time in four years, I have been subjected to this annoyance, although, thanks to the comparative absence of frost, and my growing-stuff being chiefly half-hardy, no damage has yet been done. If, however, it was necessary to force, or to maintain a moderate heat, it would, under present circumstances, be almost impossible. Of course I shall be told that the stokehole ought to be properly drained. This is quite true; but, if this can only be done at great cost, it is evident that it is easier to give the advice than to put it in practice, and I therefore wish to know whether our hot-water engineers cannot devise some means which will enable us to dispense with these stokeholes altogether? Cannot boilers be constructed more horizontal in shape, rather than perpendicular, and the piping be fixed higher in the houses than is now commonly the case? It is, I believe, a fact that a 3-inch pipe, fixed near the sides of a house, is more powerful in its effects than a 4-inch pipe placed on the ground line, and, by having the heat near the wood-work and glass, both would be kept drier and more enduring. The cold air that penetrated through interstices in the building would thus be more quickly warmed than is now the case. There has been a mania of late for large boilers, or those of novel shape, but little has been done in the way of improving their construction, especially as regards setting, when required for a small quantity of glass. Now-a-days the cost of a large boiler, which is heavy in itself, is almost doubled by the cost of fixing it. Nothing less than an enormous well appears to answer for this purpose. Thus, where a large extent of glass is used, a leakage in the boiler may in a moment produce a complete collapse of the entire heating power. Mr. Fish (page 58) makes some remarks on this subject, and I am pleased to see that he discountenances the practice of setting boilers under their work; but I fear that in the case of very large boilers it is almost a positive necessity. It would be a matter of great interest to all who have glass houses under their charge if the question were taken up and decided once and for all. If it could be proved satisfactorily that a sunken boiler is unnecessary, the discovery would be hailed with some satisfaction, and would almost revolutionise our present heating arrangements. A. DEAN.

Bedfont.

THE HERBACEOUS ROSE MALLOW.

IN most of the brackish marshes in the Eastern States a beautiful species of the Rose Mallow grows quite abundantly. Its botanical name is *Hibiscus moscheutos*, and it belongs to the great Mallow family of plants, which includes the Cotton okra or gumbo, Hollyhock, Rose of Sharon, and many other well known, useful and ornamental, herbaceous and shrubby plants. Of the Rose Mallow there are also quite a number of distinct species found growing wild in various parts of America. They are rather coarse-growing herbaceous plants, with stems varying from $\frac{1}{2}$ inch to 1 inch or more in diameter, and from 2 to 8 feet high. The most common species in the Atlantic States is the one named above. Its flowers are very large, being from 4 to 6 inches broad, varying in colour from a pure white to a deep rose, some having a dark centre, others being without it. The salt marshes in the vicinity of New York, as well as elsewhere along the coast, are dotted with clumps of these plants, which bloom through the early autumn. According to the correspondent of the "Daily Rural Life," who writes so charmingly in "Moore's Rural New Yorker," these Mallows make the extensive salt meadows, as they are termed, quite attractive flower gardens. In fact, there are few more showy or beautiful plants at this season, and it is often wondered why it is not more frequently seen in cultivation. The wild or cultivated plants produce seed in abundance, and they grow as readily as the most careless gardener could desire. When raised from seed, the plants "sport" very widely, and many shades of colour are frequently produced from those taken from a single pod. Many hundreds have been raised with the hope of obtaining a double variety, but without success; yet, as we have double Hollyhocks and double Rose of Sharon, there would appear to be no natural obstacle in the way of obtaining a double Rose Mallow. We write this with the hope of prompting others to take a hand in experimenting with seedlings of this showy and in every way desirable American plant. It will thrive in high dry ground as well as in the low and wet.

Xerophyllum asphodeloides.—I saw this rare and beautiful hardy plant, which grows in Grass-like tufts, flowering freely in the York Nurseries last summer. Its leaves are from 4 to 20 inches in length, and not more than the eighth of an inch in width; their upper surface is flat, the under sides convex and furrowed, and the edges are furnished with minute teeth, resembling those of a miniature saw. The longer leaves are gracefully recurved, while the shorter ones, which are in the centre, are more or less erect, forming altogether a graceful circular plume. The flowers, which are white, are produced in an erect spike from 12 to 18 inches high; and, although the individual flowers are not large, yet, owing to the abundant way in which they are produced, the general effect is most beautiful, the erect stem contrasting, in a striking manner, with the tufts of graceful recurving leaves at its base. When this plant comes to be better known, it will doubtless be extensively used for table and other decorative purposes, for which it is admirably adapted, as the leaves are of such a texture as to withstand the effects of dry air and gas. This I have proved, having had a plant of it in a room during the past three weeks. The pot in which it grows is placed on the stand of a moderator lamp, the base of which is surrounded with Ivy-leaves, interspersed with a few flowers; while the longer leaves of the *Xerophyllum* gracefully recurve and fall over and conceal the upper portion of the stand, thus forming a very ornamental and pleasing object, and one which has been greatly admired. Although this plant will grow and thrive tolerably well in ordinary garden soil, yet it succeeds best when planted in a compost consisting of equal parts of peat, loam, and white sand. It forms a handsome object planted on rock-work. It is a common plant in the Pine barrens of North America, from New Jersey and Oregon southward.—R. P.

Alonsoa linifolia (Roezl.).—This *Alonsoa* is said to grow from 1 to 1½ feet in height, and to be bushy and compact. The centre branch, as well as the surrounding ones, are so displayed as to form a symmetrical and graceful specimen, the component parts of which are covered from almost the base to the summit with innumerable glowing light scarlet blossoms. This species surpasses in every respect the few sorts of the genus *Alonsoa* at present known. An uncommonly free-flowering nature and dwarf graceful habit, combined with an exceedingly pretty dark green Flax-like foliage, agreeably contrasting with gay-coloured flowers, are characteristics possessed by this novelty, which cannot fail to procure for it rapid and universal cultivation. It is easily grown, and is susceptible of both pot and open ground culture. Employed either for large or small masses, or as isolated specimens, the *Alonsoa linifolia*, bearing as it does a striking resemblance to certain of the elegant foliaged New Holland plants, will produce a surprisingly beautiful effect. Sown in March, this annual will flower early in July.—W. THOMPSON.

NOTES OF THE WEEK.

— WE have just seen a beautiful photographic representation of a specimen Orchid, *Angræcum sesquipedale*, which has recently borne twenty-three fine flowers in Mr. Wilkin's collection at Leyton. It represents, we believe, the finest specimen of this singular species hitherto produced in this country.

— MR. ROBERT BROADWATER, Master of the Fruiterers' Company, will, we are informed, preside at the thirty-second anniversary festival of the Gardeners' Royal Benevolent Institution, to be held at the London Tavern on the 2nd of July next.

— MR. W. THOMSON has brought under our notice forced flowers of a kind of Bladder-nut (*Staphylea escallonioides*), which is now being used in bouquets and "button-holes" in Covent Garden. The flowers are borne in clusters, and are of a snowy whiteness with a satin-like lustre. The perfume is of a peculiar but very agreeable character. As these flowers combine the lustrous whiteness of the Tuberose with the elegance of the Jasmine, it is singular that their value for decorative purposes has been so long overlooked.

— THE "Journal de la Société d'Horticulture" has an article on indiarubber-producing plants. This paper is a collection of well-known facts relating to these valuable plants, the only point of interest being in connection with the Central American Caoutchouc tree (*Castilloa elastica*, Cerv.), which, we are told, in the district of St. John, in Nicaragua, furnishes employment to from 600 to 800 persons, in drawing off the juice. In the neighbourhood of Parma about 2,000 persons are so employed.

— IN the present crisis of the Royal Horticultural Society's affairs (writes Dr. Denny), the policy of the Fellows is to request the council to open at once communication with Her Majesty's Commissioners, with the view of transferring the gardens to them, under satisfactory arrangements for the debenture holders and the life and local Fellows, and with a *locus standi* there for shows and meetings. The Fellows, he adds, have but to be united and act with vigour and determination, and the thing is done.

— THE last number of the "Florist" contains a coloured plate of two beautiful new show Pelargoniums, raised by Mr. Foster. One of them, named Constance, is a fine round rosy flower, suffused with bright vermilion, and has a dark feathered blotch on the upper segments. The other, Crown Prince, is a rich rosy-crimson flower, the upper segments of which are nearly entirely black. It is said to possess a dwarf habit, and to be a profuse bloomer. The second plate represents a new French Pear, raised by M. Morel, and named Souvenir du Congrès, a variety which closely resembles a large specimen of Williams's Bon Chrétien. It ripens in August and September, and comes in just after the last-named variety. It is grown by Mr. Dancer, at Chiswick, and also by Mr. Rivers.

— AN important discussion took place the other day, at a meeting of the Society of Agriculturists of France, on the best means of "stamping out" the Phylloxera in French Vineyards. M. Blaise disputed the legality of the acts of certain prefects, in uprooting all the Vines attacked. Baron Thenard thought otherwise, and justified the adoption of vigorous radical measures for the extirpation of the pest which threatens all the wine districts of that country. M. Victor Lefranc declared that such extreme measures were unjustifiable; there is no similarity, he contended, between the cattle-plague, which is destroyed with the animal infected, and the Phylloxera, which remains after the plant infested is destroyed. There is every hope that such an enormous waste of capital may be avoided, by the discovery of a remedy—nearly attained, though as yet unknown—operating through the extinction of the plague, rather than by the entire destruction of the affected Vines. The meeting passed a resolution, deprecating the compulsory uprooting of Vines.

— MR. NORMAN, St. Catharine's, Ontario, writing to the "Times" concerning the Colorado beetle, commends the Prussian Government for having prohibited the importation of Potatoes into Germany. He states that a few years ago this beetle was unknown in Eastern America, but that now it is spread over the whole of Canada to the Eastern States, producing quite as disastrous a blight to the Potato fields as the fungoid diseases so well known in Europe. Last summer he saw whole fields of Potatoes in perfect health and vigour one week, and a fortnight afterwards every portion of the foliage was eaten away to the bare stems. This, occurring before the tubers were mature, arrested their growth and ruined the crop. He adds that the only way to prevent the introduction of this pest into Britain is to follow the example set by Germany, and to include Tomatoes, which are also liable to the attacks of this beetle. The most likely way of the insect being brought to us, he thinks, would be among the Potato haulm, used in packing the tubers, for the beetle does not burrow into the Potato, but eats only the leaves and stems.

In shape, this destructive pest is not unlike a large lady bird (*Coccinella*); but, instead of being spotted, it is striped.

— MR. HERBERT asked the Chief Secretary for Ireland, the other evening, whether Her Majesty's Government had taken any steps to prevent the introduction of the Colorado beetle into Ireland by the importation of American seed Potatoes or otherwise; and, should no precautions have already been instituted, what were the intentions of Her Majesty's Government on this subject.—Sir M. H. Beach said the subject of the hon. member's question was brought under his notice some time back, and he thought it right first to ascertain what steps had been taken by foreign Governments in the matter. He found that the only Governments which have taken any real action are those of Austria and Belgium. The former has assured the Government of Switzerland, which had warned the European maritime countries of the possible danger, that the importation of American Potatoes would be prohibited; and the Belgian Government has introduced a bill for a similar purpose, which has been agreed to by a special committee. He had also made inquiries as to the nature and extent of the evil to be apprehended. He thought there is reason to suppose that the harm recently done to the American Potato crop has been much exaggerated, and is informed that the insect in question has been known in America for more than a century. It attacks the stalks and leaves of the Potato plant, not the root, though that naturally becomes diseased in consequence. No Potato stalks or leaves are imported from America, and, as only healthy roots would be imported, it would seem hardly possible that the insect could be thus conveyed into this country. He is now in communication with the English Privy Council on the subject, because it is obvious that if any preventive measures are adopted they ought to apply to the whole of Great Britain as well as to Ireland. But he must add that the importation of Potatoes into the United Kingdom, especially in the event of a failure of the home crop, is very large, and that, therefore, any interference with this trade would require careful consideration.

— MR. M'LACHLAN, treasurer to the Entomological Society, writes as follows in reference to this matter:—"As an entomologist it is with feelings of regret that I read the reply (as reported in the "Times") of the Chief Secretary for Ireland to Mr. Herbert's question as to whether the Government had taken any measures to prevent the introduction into Ireland of the Colorado Potato beetle. Without being an alarmist, I consider that the right hon. baronet's reply is calculated to produce an unwarrantable feeling of security. It is stated that the insect had been known in America for more than a hundred years. Very possibly it has existed there from time immemorial, and it is probable that its real home is Central America, where it fed upon wild members of the same order of plants (*Solanaceæ*) as that to which the Potato belongs. But less than fifteen years ago it commenced a northern and eastward progress, finding, unhappily, in the cultivated Potato an abundance of food suited to it; and it has now entered the Dominion of Canada, showing a power of rapidly acclimatising itself as astonishing as it is destructive. In the reply to Mr. Herbert stress is given to the fact that the insect attacks the stalk and not the roots. The actual position is, that the eggs are laid upon the leaves or stem of the Potato plant; the larvæ devour these, thus preventing the formation of tubers or killing the plant altogether. The larvæ, when fully grown, descend into the earth to undergo their transformation into beetles, and there appear to be several broods during the year, the beetles produced from the latest hibernating in the earth and becoming the parents of the spring brood. A large importation of Potatoes from America into this country has, I believe, existed for some time. That the most destructive larval stage of the insect should accompany these importations is improbable. The real danger consists in the possibility of the pupæ or perfect beetles being conveyed with the tubers, especially in cases where the earth has not been thoroughly removed, and it is by no means an impossibility that the beetles might also be imported, still living, in portions of haulm, especially if this be used for packing, as is often done by our own Potato-growers. That the amount of its ravages in America may be exaggerated is possible; but that enormous damage has been done is certain, and to such an extent as to render exaggeration justifiable as a means of exciting public attention to a full knowledge of the existence of the evil. I have, I think, shown how it is possible for the pest to be introduced into Europe, and it will be wise and prudent that caution be exercised. That some of the most destructive insect-pests (the Phylloxera, for instance) have been introduced from America there is every reason to believe; and, on the other hand, the evil has in some instances been reciprocated. Our common small white butterfly, so destructive here to Cabbages and all Coleworts, was unknown in America until five or six years ago, but each year shows its greater extension and destructiveness."

THE GARDEN IN THE HOUSE.

FOLIAGE FOR HEAD-DRESSES.

It is well-known by ladies who use floral decorations in their hair at evening parties, that the flowers stand the heat of the head, and the rough usage of a light shawl thrown over them, far better than the leaves do. One lady of my acquaintance is very careful to harden off her plants of Maiden-hair before cutting the fronds; another lady always soaks her cut fronds in cold water for at least twelve hours before using them; a third presses and partially dries her Maiden-hair for two or three days before the fronds are wanted; a fourth is particular in only using those fronds which have brown seed-vessels on the under side, and in keeping them in slender glass tubes full of water, which are concealed under the plaits of the hair. To these, and to others interested in the matter, I commend the leaves of that beautiful greenhouse evergreen shrub, *Lomatia propinqua*, as the most durable kind of delicate foliage with which I am acquainted. The accompanying illustration shows a leaf which had been worn for two evenings before it was sketched. The only preparation which it requires is to twist a piece of wire round its stem, making a loop at the end that it may be secured with a hair-pin. A few pips of common scarlet Geranium or Hyacinth, properly wired, and arranged judiciously amongst the leaflets, form a simple and pretty head.

Leaf of *Lomatia propinqua*.

dress, which is quickly made up and easily fixed in the hair. Many other flowers might be similarly used, if care be taken to choose a leaf of a size proportionate to that of the flowers which are to go with it.

W. T. P.

DO VARIETIES WEAR OUT?

THE old Greendale Oak tree here is, perhaps, one of the oldest trees in Britain, and the only thing known concerning its history is, that it was an aged tree at the time of the Conquest. At the present time it girths nearly 50 feet in circumference above the carriage road cut through its immense bole, or about 11 feet from the ground. On one side of its giant trunk the timber and bark have long since been dead, and this side has to be supported by means of strong pieces of timber fixed in the ground, and placed underneath the strongest branches. On the other side the tree is still alive, the main branches being about 60 feet in height, and, in favourable seasons, Acorns are still produced on them. These Acorns are not so large as on younger Oaks, but grow quite as well, and the young trees raised from them are quite as healthy as any in the young plantations here. The plantations in which the trees have been raised from this patriarchal Oak are all marked with iron plates, and the date of the year in which they were planted is stamped on them. For the last thirty years I have been in the habit of picking up a few Acorns of this tree, and raising young Oaks from them to give away to people anxious to plant them, on purpose to say that they were from seeds of the Greendale Oak. Experience leads me to agree with Mr. Fish (p. 103), "that varieties cannot be said to die out from sheer lack of vital force, weakness, or old age."

W. TILLERY, Welbeck.

THE FRUIT GARDEN.

THE GRAPE VINE.

(Concluded from page 86.)

Stocks for Weak-growing Varieties.

SOME of the weaker-rooting varieties of the Vine are much improved when grafted on kindred sorts of more vigorous constitution. The reciprocal of the stock and scion is not fully understood as yet; but it is sufficient for practical purposes to state here, with regard to the Vine, that the stock should be hardy, vigorous, and fruitful, and in constitution and habit similar to the scion or variety to be grafted upon it. I prefer to give this rule as a general guide rather than name, as suitable for stocks, any kinds which may not prove to be so in all situations. Vines differ in a remarkable degree in different soils and situations, but no one is likely to err in grafting on established plants that are in a healthy and fruitful condition. For instance, though the Barbarossa is considered to be one of the worst stocks, being a very late variety and an unusually shy bearer, I would not hesitate to graft upon it where it did happen to be fruitful, as I have seen it at some places. Under the care of Mr. Henderson, of Thoresby Park, it has fruited most freely, and the bunches, in symmetry and appearance, were perfect. In such circumstances, no doubt, these good qualities would have been imparted to another variety worked upon it. The Black Hamburgh, Muscat of Alexandria, Lady Downes, Raisin de Calabria, Royal Muscadine, Trebbiano, and Alicante, are all varieties that generally succeed well, or best, upon their own roots, and they are also among the best for employing as stocks. The Golden Champion—a grand Grape—succeeds best, according to Mr. Thomson, of Drumlanrig, when grafted on the Muscat of Alexandria. We had it in fine condition for several years on the Black Hamburgh; but, when the Vines came to be forced early, it entirely ceased to show fruit, while still growing vigorously, and had to be cut out, though the other limb of the Vine (the Hamburgh) continued fruitful. Mrs. Pince, with us, makes by far the finest bunches on the Alicante, the bunches being broader shouldered and more shapely. On the Lady Downes it does well, but the bunches are hardly so large, and are more cylindrical. On its own roots it is comparatively worthless, and these differences are all observable upon Vines of the same age, and growing in the same house. Buckland's Sweetwater, a good Grape, and one of the earliest of early white Grapes, but a somewhat shy fruiter, is also improved when grafted on the Black Hamburgh; so also are the Frontignans, which are generally weak rooters. Indeed, it is better always to graft than to plant weak-growing kinds, more especially when the border is already in possession of the roots of established Vines.

Diseases and Insects which Attack the Vine.

Mildew.—This is one of the worst diseases that affect the Vine. Fortunately, it does not very often attack Vines grown under glass in this country, and good culture and attention will generally ward it off; but, when it does get established upon the plants, it is most destructive in its effects. It is generally the result of unhealthy root action, a too low temperature when the Vines are in full growth (thereby predisposing them to the disease), a stagnant atmosphere, insufficient ventilation, or, in fact, anything which lowers the vitality of the Vine when it is growing. Intelligent treatment, therefore, such as we have often recommended in former chapters, is the best preventive. The disease should always be watched for, however, as preventive measures, when it does occur, are only successful when taken early. It always appears at first upon the surface of the leaves, in the form of small white dusty-looking specks, just indicating that the parasite has taken hold; but it will often appear over a whole house of Vines before its presence is noticed or even suspected, and, if not checked, it spreads over the leaves with marvellous rapidity, killing the tissue wherever it establishes itself; eventually it reaches the berries, covering them as with a white hoar, destroying their skin as it does the tissue of the leaves, and utterly spoiling the crop and seriously injuring the health of the Vines. It can only be checked, when it does appear, by timely action, and sulphur is the only remedy.

The sulphur should first be mixed with a small quantity of milk until it is thoroughly disintegrated, then poured into a pitcher of water, and applied to the Vine with a syringe until every leaf is wetted. This will seldom fail to destroy the parasite, though it may have to be applied more than once. In winter the Vines should be washed, and afterwards painted with sulphur and milk.

Shanking.—This is a disease incidental to bad culture and certain soils, and is, more or less, well known to all Grape growers. The disease attacks the foot-stalk of the berries at or after the stoning period, when the berries are changing colour. They lose their fleshiness, have a disagreeably acid taste, and soon shrivel and drop off if the bunch is shaken. In aggravated cases the whole crop is sometimes lost for several years in succession. Various causes have been assigned for the disease: such as great disparity between the temperature of the border and that of the vinery, heavy cropping, excessively high temperatures, &c. No doubt debility, arising from any cause, will help to bring on the disease; but it is a fact that it will attack in its worst form Vines that possess the greatest apparent health and vigour as regards wood and foliage, and where the highest skill is brought to bear on their culture. One of the worst cases of shanking that ever came under my notice occurred in Vineries where the borders were all inside, and were heated with hot-water pipes. The borders were made of the most approved materials and nothing was wanting, it was thought, to ensure success. The Vines grew vigorously, and were not cropped till the third year, and then only moderately; the bunches were large and promising, but nearly every berry shanked up to the foot-stalk of the bunches; and this went on more or less for years, till the Vines were pulled up. I ought to state, however, that shanking had always been unusually troublesome in the place, attacking both young and old Vines, pot Vines, and Vines growing in outside and inside borders; and it went on under the superintendence of different gardeners, who, before and afterwards, produced excellent Grapes in other parts of the country. We are forced to the conclusion, therefore, that the disease must have been due to something in the soil, or to its deficiency in some quality or other which was needful to the well-being of the Grape. The staple of all the borders was turf from pastures, of a light texture, and from a gravelly sub-soil, and lime scraps were added to it. It would, seem, therefore, that shanking may arise from circumstances over which one may have no control, so far as our present knowledge of the disease extends; but I have invariably observed that it was least troublesome in heavy soils. In our very heavy soil here, shanking is quite unknown; nor, though good and indifferent Grape-growing may be seen in the district upon the same formation, I have never seen any serious cases of shanking. Under these circumstances, I feel I cannot offer any specific advice on the matter, further than is contained in my former remarks on the subject of soil, border-making, watering, airing, temperature, &c., which, if carried out, will go far towards preventing the disease.

Red Spider and Thrips.—The first-named of these two plagues is most to be feared, though thrips, individually, are by far the most destructive; but, as they do not breed so fast, they do less damage. Red spider is always most destructive in Vineries where much artificial heat is used, and, for that reason, experienced Grape growers dispense with fire heat whenever opportunity offers, especially at night. I can give no better advice than this, unless it is to say, "give your Vines abundance of water at the root, and contrive, by moderate temperature and otherwise, to secure a stout and healthy condition of the foliage, for red spider always finds out the weakest subjects and the weakest varieties." Syringing as often as possible will help to keep the Vines free, and it is well worth while to wash the leaves with a sponge and soft water whenever they are observed to be affected. The same preventive measures should be taken with thrips, and they may also be smoked successfully with tobacco paper; but not after the Grapes are ripe, as the tobacco strongly affects the taste of the Grapes.

Rust.—Rusty Grapes are the result of contact with some other object, such as the hands or the head, or sudden draughts of cold air against the berries when they are just

set, and, above all, of very hot pipes at that time. I am perfectly convinced that excessively hot pipes will produce rust on any variety of Grapes sooner than anything else. Of many well-proved cases of this, I will give one which happened here. Some years ago the man in charge of the Vineries inadvertently let the pipes get too hot in a Muscat and Hamburgh house, when the berries had just set; the pipes were so hot as to smell strongly, and blister the hand when held upon them. They were not so long, however, for, anticipating the consequences, I had the pipes emptied as soon as discovered, but not soon enough to save the Grapes. The rust was visible a day or two after, being worst round the ends of the houses, and along the front—in fact, everywhere near the pipes, and gradually getting less and less further up the roof. The Hamburghs were the worst affected, but some of the Muscats were bad enough. Lady Downes and Black Alicante seem less susceptible than most other varieties; but they, too, take it occasionally. I have frequently had a few bunches rusted in one particular corner of our late Vinery, where they hang rather near the pipes. My advice, therefore, is, "avoid all these causes, and rather do with low temperatures in cold weather than too hot pipes."

Warty Leaves.—It has often been asserted, in horticultural journals, that the warty excrescences which appear on the under side of the Vine-leaf, under certain circumstances, do no harm to the Vine; but this is a great mistake. The warts are the constant result of a close damp atmosphere and insufficient ventilation; they never appear under any other conditions. The warts first appear thinly scattered over the leaf; they get thicker and thicker until they coalesce; the leaves become cupped and crimped; the growth of the plant is completely arrested, and no curative measures will restore it to health again after it gets to this stage, though sulphur on the pipes will kill the warts. The only preventives are a dry atmosphere and plenty of air. It is a disease that should never occur to any serious extent under ordinarily good culture.

Scorching of the Berries.—This scorching, which takes place when the berries are about half-swelled, is almost confined to the Lady Downes Grape, and is sometimes very destructive, but scarcely ever so under good management. The damaged berries appear black and discoloured on one side, the tissues being simply killed, as if the berries had been dipped in boiling water. When it appears, the temperature should be lowered a little, and more air and a drier atmosphere given. This generally prevents further destruction. Vines that are not forced too hard, but brought on gradually with a free and constant circulation of air in the house, are seldom affected.

J. S.

SMALL HOUSES BEST FOR MELONS.

WE grow our Melons here in comparatively small houses, and owing partly to that, and partly to a careful system of cultivation, we have few failures. As a rule we sow the seed in January; and, as soon as the plants are large enough to handle, they are potted off singly in 60-sized pots and are placed in a Cucumber-house. As soon as they have acquired sufficient size they are planted upon a ridge run along the centre of the bed in which they are to grow. The soil for early work is not compressed so firmly as that for late Melons, because we find that the plants grow faster in light soil than in hard material. As soon as the roots show themselves on the outside of the ridge more soil is added, until the beds are 2 feet 6 inches wide and 10 inches deep; the soil consists of three parts loam enriched with one part cow-dung or Mushroom-bed manure. From the time when the plants are started into growth until they begin to ripen their fruit they are never allowed to become dry, and the water applied is always of the same temperature as that of the house; if anything, warmer. I also water frequently with manure-water, such as drainings of stables, &c., largely diluted. Thus encouraged, the plants grow vigorously, and soon reach the wires, on which they are trained like Cucumbers; and, as soon as the fruit is set, say two or three on each plant, the shoots are pinched back to one or two joints beyond the fruit, and all superfluous growths are removed. Melons should be looked over daily; it is bad

practice to leave them for a week or so and then cut away a barrowful at one time. If bleeding occurs, dust the wounds with slaked lime; and, if symptoms of canker or rot appear, the same application will often be found to stop them. I always endeavour to keep the collar of the plants from the time they are planted out until they have finished growth level with the surface of the bed. In fertilising the blooms care is required, especially if more than one kind is grown in the same house. After trying many varieties, I have come to the conclusion that Meredith's Hybrid Cashmere, Victory of Bath, Scarlet Gem, Bailey's Eclipse, and Royal Ascot are the best. I have tried Munroe's Little Heath, but it did not succeed with me. I syringe liberally in summer, as early as 7 o'clock in the morning, and at the same time give a little air, although we never open the ventilators, even at midsummer, more than 2 inches. This is done at top, or, rather, the back, as no air is given in front. In the afternoon I syringe again just as the sun is getting off the houses, which are shut up hot and well deluged with water, except during the time when the fruit is setting, and then plenty of water is thrown on the paths. During the early part of the season air must be given with caution, for, if Melons once get chilled, a considerable time elapses before they recover. As the season advances the beds in successional houses are made up to the desired height without the ridge, and they are pressed almost as hard as cement—a practice which keeps the plants strong. Bottom-heat is furnished by a flow and return hot-water pipe placed underneath the slates which form the bottom of the beds, and top-heat is also obtained by means of hot-water pipes. I am not an advocate for taking two or three crops from the same plants, for, if a crop of Melons is finished off properly, there will be little left for a second or third crop. Three or four small houses producing crops in succession will be found to be much the best. The temperature never ought to fall below 65°, indeed, I have frequently syringed and shut up when the thermometer indicated 100°, but, of course, this heat soon cools down after sunset.

D. S. GILLET.

Court Garden, Great Marlow.

BOUGHT v. HOME-GROWN VINES.

MR. MUIR's assertions and figures are alike delusive, a fact which his own statement that "the poorest fruiting pot Vine will bear at least 10 lbs. of Grapes" is sufficient to prove. I am at a loss, also, to account for another statement which he makes, viz., that "as a rule, pot Vines are grown in spare corners of structures heated for other subjects." I believe pot Vines have, as a rule, a low house or pit to themselves, or perhaps Strawberries and French Beans for companions. Every gardener is well aware that bought pot Vines seldom pay as a market crop on account of the first cost, the extra attention required, cost of fuel, and labour. If, indeed, the results are as good as Mr. Muir attempts to show by his figures, how is it that Grapes are so little cultivated by fruit-growers for market? Simply because they don't pay. They serve a useful purpose in enabling private gardeners to save their permanent Vines and cut a few early Grapes, and it is mainly on that account that they are grown. I know that there is no more harm in buying ready grown pot Vines than in the purchasing show plants immediately before an exhibition; both practices are known and permitted, but I maintain that as good Vines are grown in hundreds of private gardens as are ever sent out by the trade, and Mr. Muir has failed to show the contrary. Mr. Muir should consider that many of our most noted "trade" growers of Vines were private gardeners, and that, in some cases, the very Vines from which they are now cutting Grapes and propagating pot Vines were raised in private gardens. Let Mr. Muir name the grower who cuts 3½ lb. clusters of a nameless variety from his weakest and discarded canes.

J. CHURCHILL.

Whalley Range.

Had not Mr. Irvine and Mr. Churchill brought my name into this discussion, I should have allowed Mr. Muir's communication to pass unnoticed; but being called upon to vindicate the private grower, I do so with pleasure. How can a man be a skilful Grape grower, let me ask Mr. Muir, unless he can grow Vines in pots? I have seen Vines in pots grown by gardeners when Mr. Muir was scarcely old enough to know what a Grape was, and grown well enough to carry off silver medals at the Chiswick Gardens, where they were exhibited with the fruit attached. Should, however, any of the contributors to THE GARDEN desire it, I can furnish them with

clear proof that in many instances "home-grown pot Vines are superior to bought ones," and Mr. Muir should re-arrange the heading and contents of his article, if he wishes to free himself from the error into which he has fallen. No doubt, Mr. Muir had in his mind's eye, when writing, some particular Vinery; and we do not for one moment doubt that the Vines grown in pots there are of the best description. But Mr. Muir must recollect that one place does not represent the three kingdoms; thousands are grown yearly about London alone, and it is to pot Vine-growing generally that my remarks refer. The generality of pot Vines are grown in huge span-roof houses, plunged in a tan bed in the middle of the house, and packed thickly. They are subjected to a strong heat, both top and bottom, are kept moist, and are grown rapidly. All the Vines have stakes to keep them straight, and, when full grown, they are one mass of foliage, perfectly impenetrable to either light or air; therefore, what is to form the fruit buds? The fact is, only about half a dozen eyes at the top of each cane get ripened. I have myself bought twenty pot Vines at 12s. 6d. each, and the whole only showed sixteen bunches.

R. GILBERT.

[Here, we think, this discussion should end.—ED.]

RAISING VINES FROM EYES IN TURF.

MR. MUIR's statements (p. 108) in reference to this matter are incorrect; at least, I must consider them to be so until he vouches for both the time and the place where he saw the practice in operation before 1867 or even 1871. The practice has, at all events, become identified with my name, and was copied, as described by me years ago in the "Gardeners' Chronicle," into several horticultural journals, including some of the Continental ones, and no one then thought of disputing the priority of the practice. As to the Lady Downe's house at Dalkeith, I prefer to believe the evidence of my own eyes and that of Mr. Thomson, who, at p. 273, 1871, of the same journal, states distinctly that he did not raise the eyes from turf. But, just to show how much your correspondent knows about what he writes, I may state that the Lady Downe's Vinery at Dalkeith—of the history of which I could furnish him with every particular, from beginning to end—was not planted with young Vines from eyes at all, but, throughout, with one-year-old plants cut down. So much for the veracity of those who "assured" Mr. Muir to the contrary; and if he desires further confirmation of the truth of this, I refer him to page 31 of Mr. Thomson's book on the Vine. After the knowledge Mr. Muir has displayed of recent horticultural literature, I am quite prepared to believe that he may have both seen and practised the sod system of raising Vines, without knowing its history; and that he should, by this time, have discovered the plan to be worth recommending and practising, is what I should expect.

J. SIMPSON.

Wortley.

Distances at which Pear-trees should be planted from each other.

	ft. in.		ft. in.
Standards on Pear stock ...	16 3	Cordons, oblique, single ...	1 7
Standards on Quince stock ...	13 0	Cordons, oblique, double ...	3 3
Pyramids on Pear stock ...	13 0	Palmettes on Pear stock ...	26 0
Pyramids on Quince stock ...	9 9	Palmettes on Quince stock ...	13 0
Pyramids on Pear and Quince alternately ...	6 6	Palmettes, alternate ...	13 0
Columns ...	4 10	Palmettes in the vertical form, called Verrier, with one series ...	3 0
Cordons, horizontal, with one or two branches ...	9 9	Verrier with two series ...	4 10

and so on, increasing at the rate of 2 feet for every additional series. Standards on the Pear stock are only admissible in gardens where the soil is of inferior quality, or in the case of varieties which do not succeed on the Quince. In the open fields, where none but vigorous varieties are planted, and where the trees are very much left to themselves, the distance should be, at least, 32 feet.

J.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

What are the Best Filberts, and how Should they be Grown?—I wish to plant a considerable number of Filberts, and shall be much obliged if some of your readers can enlighten me as to the best kinds to grow, the soil on which they thrive best, the distance at which the trees should stand from each other, if they require manure, and, if so, what kind, and any other hints as to their culture.—E. A. N., *Kent*.

Tobacco Dust a Remedy for Bleeding in Vines.—After pruning our early Vinery this winter a Muscat of Alexandria commenced bleeding profusely from more than one wound, owing to its proximity to a warm drain, through which pipes are led to a range of plant-houses. We tried various remedies for stopping the bleeding, but without effect until we used Pooley's tobacco dust, which was rubbed well into the wounds, dusting them afterwards with the dry dust. The effect was almost instantaneous, the wounds being sufficiently dry in a few hours to receive a dressing of Thomson's styptic.—WM. M. BAILLIE, *The Gardens, Beaufront Castle, Hexham*.

RATS AND MICE AS GARDEN PESTS.

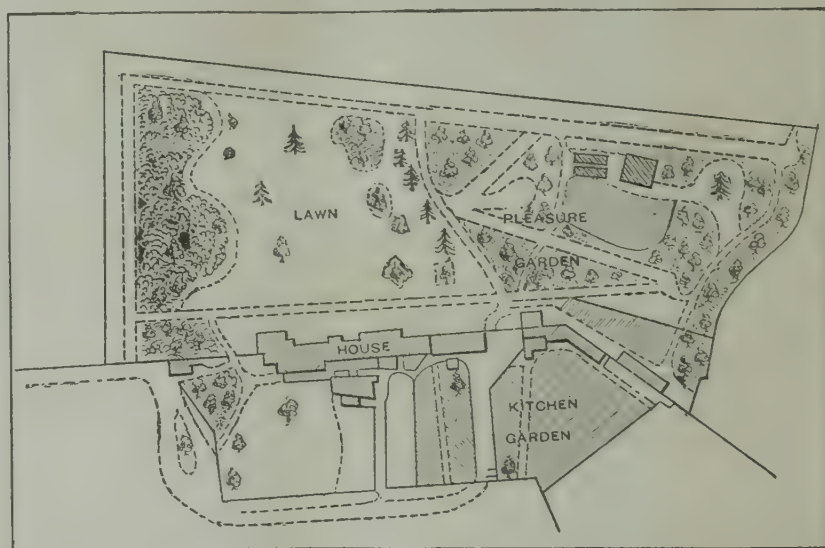

THE common small water-rat is considered a harmless little animal that usually confines his operations to the margins of ditches or small running streams; but, like all the species, he is endowed with a considerable amount of cunning, and, I fancy, he is sometimes guilty of committing depredations for which he is held blameless. I was looking in a neighbour's garden the other day when my attention was called to his Broccoli and Winter Greens; the bark was in many cases completely eaten off all round the stems, in some instances the stems were nearly eaten through, and of course most of them will die. The mischief was done by water-rats that had entered his garden from a watercourse near. I remember a somewhat similar circumstance, which for a short time puzzled me exceedingly, occurring, about fourteen years ago, in a garden I had charge of in Norfolk. Many of the Winter Greens had been barked, and in some instances the stems eaten quite through at the bottom, whilst the only indications of the presence of any enemy in the immediate neighbourhood were two or three small hills, not unlike mole hills, which, on examination, were found to be connected with an old mole run. I at first thought the mole, contrary to his usual custom, had become a vegetarian, and several traps were placed in spots most favourable for capturing him; but, in the course of a day or two, two of the small water-voles or rats were caught. They had by some means found their way into an old mole run, and had followed it up for a distance of 200 yards, until they burst through the soft earth in the kitchen garden. I was not sorry to find I had unjustly accused the mole; for, were it not for his disposition to overturn seed beds, I should look upon him rather as a friend than as an enemy. I think, for his size, there is no animal so savage and voracious as the common Norway rat; and, if allowed to become numerous, the damage they do, both to garden and farm produce, is immense. They are often very destructive to ripe fruit, are especially good judges of Grapes, and, either from their acute sense of smell or from the possession of some wonderful instinct, they always attack the best-flavoured fruit first. If choice hothouse fruit is not to be had, they will be content with Gooseberries or even Morello Cherries, but in all cases I will guarantee they will take the best within their reach of both fruit and vegetables. Many different plans have been suggested and described for their destruction, both in the way of traps and poisons; but in dealing with poisons some experience in their manipulation is necessary, in order to be successful. The best rat-killer I ever knew was a Norfolk man. His mode of proceeding was simple enough; but the materials he used, and his way of dealing with them, was a trade secret which he would not divulge. When he first looked round a place infested with rats he selected his feeding places, and fed them regularly for about a week or eight days. The food was usually barley or oatmeal, flavoured with something to make it especially attractive to the rats, and it was always used in a dry state. I have seen them running about in the evening, just before feeding time, if not quite tame, at least divested of most of that fierceness of disposition common to rat nature, waiting for his coming. When he thought he had drawn all the rats together, he laid down the poison, which, as far as appearance went, differed in no respect from the food he had given them previously, and it was a rare circumstance when he failed to get rid of all. Of course, where rats are not numerous, they may be got rid of by carefully stopping all holes in buildings with cement, trapping or snaring them in their runs, and afterwards filling up their holes in the banks or hedges where they come from with broken glass, or some material they don't like to work amongst. I have seen phosphorus used for destroying rats with a fair amount of success; it is mixed with flour and sugar in the following proportions: a quarter of an ounce of dissolved phosphorus, half a pound of sugar, and the same quantity of flour, made into a paste with water, and formed into pills. When made, the pills should be kept from light and air, to avoid loss of strength, and be placed at night in the holes or any place which the rats frequent. If not placed in the rats' holes they will be safer if laid behind a board or slate, to prevent poultry or anything else picking them up. There is no difficulty in getting poison that will kill rats; the only difficulty is to induce them to eat it. Mice, in their small way, are in some places nearly as destructive as rats; but where a good cat or two can be kept, that is the best way of keeping them down. In game-preserving districts it is nearly impossible to keep a cat, as they will wander off after the game; and in places where the natural enemies of the mice and rats, such as stoats, weasle, hawks, &c., are all destroyed, traps and poison must be resorted to almost continually. The common figure of 4 trap is the very best for setting in the open air, baiting sometimes with a soaked bean, at other times, by way of a change, with hard toasted cheese or a bit of fat meat. The very best mousetrap for buildings is Pullinger's patent; I have used no other for several years. It requires no setting, and not often baiting; it is not liable to get out of order, and, with care, will last many

years. I have often caught two mice in each and at a time; and, no matter how many are caught, if the trap be cleaned sometimes, and a little fresh grease placed in the part of the trap they first enter, they never seem to get shy or afraid of entering it. It generally happens with the majority of mousetraps that when you have caught two or three the others suspect there is something wrong, and will not go near it.

E. HOBDAY.

PLAN OF PROFESSOR OWEN'S GARDEN.

ON a former occasion we gave a view and notice of Professor Owen's quiet little garden at Sheen, and now publish a plan of the same. It will be seen at a glance how simple the plan is, and, though the place is small, how ample the breadth and capacity for views. There is picturesque variety in this garden, mainly afforded by trees, which may be seen to advantage. From the cottage across the little lawn the view by the stately Gleditschia to the Corsican Pine is very pleasing. It will be observed that there are no walks in the central part, so that, when looking from any part of the sides to the centre, the effect is not marred by these objectionable surfaces. The Grass walks are arched overhead with trees, which screen them from the central parts. The one main walk around the garden is sufficient for every purpose. Even where this passes by the house it is hidden by a wide mixed border of American plants, Lilies, &c., so that, looking from the windows, nothing is seen but

Key plan of Grounds of Cottage in Richmond Park.

trees and flowers and Grass. The Grass walks are a pleasant feature in summer. The ground on each side of them is carpeted with Irish Ivy, with a few hardy Ferns and herbaceous plants here and there. Some of the taller herbaceous Harebells looked much more charming, naturalised by these shady walks, than they ever do in mixed borders where they have to be tied up stiffly.

Conifers for Low Grounds.—"Salmoniceps" is right in supposing that *Taxodium distichum* and *Thuja occidentalis* "would find themselves at home" in low situations. *Juniperus virginiana* may be found in almost every wood and uncultivated field in this district, and it unquestionably prefers a high sandy soil. I frequently notice the young seedlings growing in the most worn out and barren lands, but rarely in moist, and never in submerged, situations. *Abies canadensis* likewise thrives in low grounds, though we frequently see it in the woods about us thriving upon hillsides. I noticed in the state of Michigan a Hemlock wood extending from the half-submerged banks of a stream up a considerable and precipitous hill to its top; there was no striking difference in vigour or symmetry. The same may be said of Hemlocks along the lowlands and hills of the Hudson River. *Taxodium distichum* is abundant in the swamps of the Southern States, where the roots produce those singular conical excrescences familiarly called "Cypress knees." *Abies excelsa* and *canadensis*, *Thuja occidentalis*, and even *Pinus austriaca* thrive in our own grounds near the banks of a lake, and not more than 2 feet above its surface water. In contiguous grounds *A. excelsa* is noticeably more luxuriant in such situations. Last spring we planted, within 8 feet of the water's edge, a specimen, each of *Pinus Strobus* and *P. nivea* (the latter, a variety of *P. Strobus*, only differing in the colour of its foliage, which is more glaucous), but they protested against such treatment, and were removed in the fall to higher ground.—E. S. C., River Edge, New Jersey.

PLAN OF PROFESSOR OWEN'S GARDEN IN RICHMOND PARK.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Early Radishes.—If the weather keeps mild, Radishes sown in the open ground, and covered with litter, will very soon vegetate. See that they are not kept covered in the day as soon as up, or they will be drawn and weakly. The litter should be carefully taken off in the morning, and again shaken over the bed in the evening, until the plants have got sufficient strength to bear full exposure. As soon as the first sowing is up, a second bed should be sown to give a succession, to ensure which, during the spring, great care should be taken, as this crop is generally held in very high estimation in the early season, and, without the closest attention, Radishes cannot be had crisp and uninterruptedly.

Birds and Seeds.—The seeds of Radishes, Turnips, and all the Cabbage family, are particularly subject to the attacks of birds, more particularly in small gardens. In the market gardens, where radishes are sown by the acre, a boy is regularly employed to keep off these marauders. In the small breadth required in a private garden it would not pay to employ labour in that way, yet if nothing be done, a very few finches would, in a single day, destroy a crop. For many years I have, previous to sowing, dressed all seeds of the above description with red lead, and I have never found any bird touch them—except the green finch, from which nothing will preserve the seeds but covering them with mats. The dressing, to be effectual, must be done thoroughly. The best method is to place in a large tea-saucer as much seed as it is the intention to sow, on which sprinkle a very few drops of water, for if they be made too wet, the seed and the lead will all stick together in a mass; then take a teaspoonful of dry powdered red lead, and stir the whole thoroughly until all the seed is well coated with the lead; let it stand for a couple of hours to dry before sowing—this is necessary, or the lead will wash off with the rain; whilst, if laid on with the right amount of moisture, and well dried, it will adhere to the outer covering of the seed, even when it appears above ground. With a little practice in the preparation of the various seeds that thus fall a prey to birds, the amateur will soon be able to judge when he has hit upon the right degree of moisture required before applying the lead, and upon which depends the thorough preparation. Half a pound of lead will last a season, and the trouble is nothing when compared with blank crops.

Seakale.—Put in more Seakale roots for successional supply, treating them as advised for the earliest forced. If there is at command more of this vegetable than is required for forcing, it will, if the crowns are covered with 8 inches of fine ashes or sand, blanch well when it grows naturally with the warmth of the spring. To be managed in this way, it should be planted in rows, so that the covering material can be placed over it in the shape of a continuous ridge, removable as the crop is gathered. In taking up this vegetable for forcing, the whole of the long roots, from the thickness of a finger to that of an ordinary pencil, should be forked out of the ground, and laid in soil until the time comes for planting. This is better and more certain than raising the plants from seed. If some more Rhubarb roots are now put in any building where the external air in a great measure can be excluded, it will spring fast, and come in before the outside crop, and be better in quality than that which has been forced. If a few inches of stable litter is placed over the crown of the roots outside, it will act as a protection from spring frosts, and induce them to push a fortnight earlier than such as are fully exposed.

Potatoes.—Late Potatoes, required for use from the present time through the spring, should be gone over as soon as they commence to sprout. Rub the sprouts off before they have attained any considerable length, for, if allowed to remain on, they spoil the quality of the tubers for cooking. Keep them in as cool a place as possible, so that they are not exposed to frost, but quite in the dark. Carrots, Beet, and Turnips should be gone over in like manner, rubbing the young growth off them. The sand, soil, or ashes in which they are stored should be as dry as is consistent with not absorbing the natural moisture from the roots, for, if at all wet, growth is promoted, which it is the object to discourage as much as possible.

Raspberry Beds.—Hoe over the Raspberry beds, and remove any weeds, after which give the surface a good mulching with manure. From the nature of this fruit in completely renewing its wood yearly, it takes a great deal to support it, and requires, to grow it well, a greater amount of manure than any other fruit we grow. Three inches of good solid manure, placed on the surface every year, is not too much, and the crop will well repay the extra outlay. When the plants are strong, half the breadth often devoted to this fruit will suffice, and they rarely fail in bearing if grown in suitable soil, that is, of medium strength, neither too heavy or too light. The young shoots must be thinned out in the spring to something like the number required for fruiting the following season, so that all the strength of the roots is concentrated in producing the canes

only that are required and no more. If kept clear from weeds the plants will last for a lifetime, instead of requiring re-planting, as is often the case. Guano is an excellent manure for Raspberries, applied to the surface with a little vegetable soil, or as an assistant to a light dressing of stable manure, and, when there is a deficiency of the latter in the amateur's garden, a few cwts. of good guano will be an excellent substitute; but, in the purchase of this, it is necessary to be careful, remembering that there is no such thing as a cheap article under the name. When it is offered below the current price, either wholesale or retail, the chances are that it is not worth as many pence as you are charged shillings. There is one thing to be observed respecting this manure. If, after trying a sample, it is found good, there need be no hesitation in purchasing a supply that will last for years, for, if kept in a moderately dry shed, it will be just as good, in every way, at the end of a dozen years, as on the day it was imported. I have had it much longer than this, and could not detect the slightest diminution in its strength.

Glass Structures.—Where there is the convenience of stove heat, there are many things that will shortly require attention. It is now time to start some bulbs of Gloxinia, and it is better not to excite all the stock into growth at once, for, although the plants will keep throwing up flowers more or less through the summer, still the head of bloom produced after the first and principal flowering, are much fewer in number, and, consequently, not so effective. If a portion are at once potted and placed in heat, they will soon begin to push. Do not over-pot them; an 8-inch pot will grow a large bulb, especially if it is assisted with manure-water; good sandy loam is the best material for them, with one-fifth of rotten leaf mould; place an inch of crocks in the bottom of the pots, and do not quite cover the bulb, but allow its surface just to appear above the soil; pot moderately firm, and place in heat at once. Some Achimenes should be started at the same time; these are better placed thickly in shallow pans, covering the bulbs with half an inch of soil, when they have pushed shoots an inch or two long they can be transferred to the pots or baskets in which they are to be grown. They are fine decorative plants grown this way, either for a large or small house; use baskets proportionate in size to the house they are intended to grow in. Where such plants as Allamandas, Clerodendrons, and the most useful Bougainvillæa glabra are grown, they should be at once started; the fact of their being comparatively large-growing plants when encouraged to attain their full size frequently deters amateurs from attempting their growth; but they can be induced to flower freely without being allowed to get to a size that would be inconvenient, even in a small house, by simply propagating a few every spring, which, from the ease with which they are increased and afterwards grown on, is a work of very little labour. If, as usual with these plants, they have through the winter been kept quite dry, the soil will require a thorough soaking to bring it into an healthy state for the roots to push freely. This is best effected by plunging the balls of the plants in a bucket of tepid water for a few hours. If they are such as were struck from cuttings last year, and are in 8 or 10-inch pots, they may be at once moved into others, 3 or 4 inches larger, in which to flower. In the case of the Allamandas and Bougainvillæas, remove a little of the surface soil, and re-pot in good rich fibrous loam, with enough sand added to keep it porous, as these plants require much water. In potting, ram the soil quite firm. With Clerodendrons, either of the twining or shrubby kinds, do not disturb their roots by removing much of the soil, or it will interfere with their flowering. They require similar soil to the first-mentioned plants. A few of the best Ixoras should also be grown, such as *I. coccinea*, *I. amboynensis*, and *I. aurantiaca*. These will flower in all stages of their growth, from a 6-inch pot up to a full-grown specimen, 6 feet in diameter. They are likewise so readily propagated as to make it an easy matter to have them whatever size is best suited to the situation they are required for. These plants grow the best in good fibrous peat, with one-sixth of sand added, and require a similar atmosphere, temperature, and admission, of air as Cucumbers, *i.e.*, from 66° to 70° at night. The admission of large quantities of cold external air, and a dry condition of the atmosphere is fatal to the well-being of these, the finest of stove plants, as also to many others that are equally deserving of cultivation. Anything in the shape of bedding plants that can be increased by cuttings, and are required, should now be pushed on. The tops of most varieties of Pelargoniums used for this purpose, if taken off now with a good portion of firm wood, will strike in a little heat, with few failures; and if the shoots are strong and taken off a good length, they will yet make stout plants before the time comes for planting them out. Autumn-struck cuttings, that are in store pots, should be potted singly in 48-sized pots in rich soil, and encouraged by keeping them for a time in a temperature of 48° in the night. A dozen strong plants, so managed, will be more satisfactory when bedded out than double the number that are weak and puny.

THE KITCHEN GARDEN.

RAISING CELERY UNDER GLASS.

Good Celery is always welcome, and those who desire early crops must lose no time in sowing and otherwise preparing for them. It is well known that Celery, in its wild state, is chiefly found growing in marshy places, and, when in its greatest vigour, near the sea-coast, thus showing that salt, in some shape, is beneficial to its growth. Having selected a good kind of seed, take a shallow seed-pan, put an inch of crocks at the bottom, and over that 2 inches of good open loam, with one-third of rotten leaf mould; press it down until it is fairly solid, sow the seed, and lightly cover it; plunge it in a good hotbed from 80° to 85° bottom-heat, or in an early Vinery or stove—close to the glass; if in either of the latter, material for a hotbed must be got together. Fresh manure from the stable, or mixed with leaves, should be used and thrown into a heap. In the course of a week, turn it over, and mix it well together, and repeat the operation at the end of another week; this allows all the rank heat to escape, and sweetens the mass. While this is working, the seed, which is slow in germinating, will want attention. As soon as the seed-leaves are fully expanded, pull out all the weakest, leaving a space of about an inch between those remaining. This prevents a weakly growth; then replace them close to the glass, and, so soon as they get into rough leaf, place an inch of drainage on the bottom of a box about 2½ inches deep, and fill it up with a rich open compost, making it as solid as a Mushroom-brick, and leaving it an inch deep when finished; then plant in the seedlings, about 2½ inches apart every way; replace them in the same place, close to the glass, if this be convenient; if not, the hotbed must first be put together, so that it may be ready to place the boxes in as soon as they are pricked out, as all checks must be carefully avoided. In making up the bed, let it be at least 2 feet longer and 2 feet wider than the frame, as it is thus enabled to retain heat much longer. The depth must generally be regulated by the material at hand. When finished, put the frame on, levelling the inside with the same kind of material as the bed is made of, to within a foot of the top of the frame; then fill in with equal parts of soil and rotten manure, and tread it down firmly, leaving it 6 inches in depth; then place on the lights, and in three or four days it will be ready for the boxes. A little ventilation at the top is necessary, and the plants will soon take hold of the soil. Watering and ventilation must both be regularly attended to, to keep them dwarf and strong. As soon as they have filled the soil with roots, take a sharp table-knife and run it down the centre of each row through the length of the box, cutting the soil down to the drainage. Three or four days after, cut them across the box, lift them out in a solid square, and plant them in the frame, about half an inch deeper than before, and 6 inches apart; then pack the soil firmly round each plant, damp them overhead with a syringe or fine-rose watering-pot, and keep close for a few days; after which give air gradually, till they get hardened, when it must be given more freely, according to the weather. Attend to watering the roots, and damp overhead on bright days early in the afternoon, and close the lights. The plants will soon touch the glass, when the frame must be raised, and a brick placed under each corner. When the leaves again reach the glass, a second brick should be placed on the first, and then they must be gradually hardened off, the lights being taken off altogether, when the soil will be a mass of white roots. About a week before you intend to plant out, tie each plant loosely round with a thin piece of matting, or any other soft material, and run a knife down the centre of the row, the length of the frame, and give a gentle watering to settle the soil in the cut. The trench must next be prepared by taking out a graft of 8 or 9 inches deep and from 24 to 30 inches wide, as Celery makes more side than tap roots. Fill in the trench with 6 to 8 inches of good rotten manure, that the spade will go through, and place 3 or 4 inches of soil on the top of this; take a four-pronged fork and mix them well together, covering 6 inches up each side with soil, and leaving a foot open in the centre to plant in. A good time to plant out is during the first three weeks in May. When all is ready

for planting out, lift the frame off the plants, cut them across between the rows with a knife as before, take them out in squares, and plant them in the prepared trench, about 1 inch deeper than they were previously, and 1 foot apart. Give them a moderate watering when this is finished, and they will not droop on hot days. See that the ties are loosened and tied afresh when required. Give water when required, and in dry hot weather damp them overhead every afternoon about 4 or 5 o'clock. If the Celery is required for exhibiting, when it has attained the height of from 18 to 20 inches, take a piece of strong paper 18 inches by 14, double it and make it 14 inches by 9, and place one round each plant; cut off the other ties, and put one round each end of the paper. This keeps the centre from turning green, and renders very little blanching necessary. A month before it is required for exhibition give it a thoroughly good soaking with weak manure-water, raising the paper 4 inches higher, and picking off all the leaves that would go inside the paper, as they go yellow and stain the Celery. Remove every lateral, and then carefully put round the soil 1 inch on to the paper. In seven days raise the paper 4 inches, and soil up as before; at the end of another week examine the centre to see if it is straight and free, and if the paper requires to be raised an inch or two do so; if not, soil up round the paper, but be careful that none goes inside, as it might damage the centre. As regards sorts, the best I know, either as early or exhibition kinds, is "Pollit's Laddie Colt Pink." It is very crisp and solid, and a delicate colour. The best white is Lady White, and is very similar to Wright's Grove White, that came out thus labelled. Sow red the first week in February and white about ten days later, as it is more apt to run to seed; but the best preventive is never to allow it to receive a check either in planting out or from want of water, and never on any occasion give strong manure-water, as it makes it spongy, deteriorates the flavour, and very often damps out the centre.

JAMES SMITH.

Waterdale, St. Helens.

The Chiswick Broad Bean Trial.—Some may think, perhaps, that the Chiswick Broad Bean trial, an account of which you have inserted, is a matter of little importance. To me, however, the report is most acceptable, for it substantiates what I have for a long time asserted to be a fact—that the old early Long-pod is the earliest variety we have. Nine out of ten people sow Mazagan for their first crop, and, if application be made to any seedsman for the seeds of an early variety, Mazagan is invariably sent. I always disliked this kind, and have always failed to see its value for any season. I have tried it in different localities, and always with the same bad result, and I have come to the conclusion that it is a poor, late, and altogether insignificant variety. No cooks care to have anything to do with it, nor does it give satisfaction when placed upon the table. If so, why is preference always given to the Broad Windsor? Why the Mazagan should ever have gained the reputation it has for being early is to me a mystery, but I am glad of the opportunity of endorsing Mr. Barron's report, and of exposing the error. My father, years ago, had the same low opinion of the Mazagan, and would neither sell the seed nor grow the variety. The Long-pod, I may add, stands frost well with us. Beans should be sown in rows 2 feet 6 inches apart, and 4 inches asunder in the row.

—J. TAYLOR, *Hardwicke Grange.*

Gherkins in Market Gardens.—These are sown about the middle of May in rows 4 or 5 feet apart, and the seeds are put in about 4 or 6 inches asunder. A good place for this crop, and one often devoted to it, is the alleys between the rows of spring-sown Cabbages or Radish beds. The alleys are dug over, the drills for the seeds opened in the morning, and the seeds are sown in the afternoon when the ground is warm. When the Radishes or other crops are cleared off the intervening beds, the latter are dug, and a line of Cauliflowers or French Beans is planted along the centre of them, or sometimes two or three lines of Lettuces are put in. Some sow the Gherkins on an open quarter in patches of three or four seeds together, in rows about 5 or 6 feet apart, and 3 or 4 feet asunder in the row. Hand-glasses are then placed over the seeds, and when the young plants have come above ground, abundant ventilation is given until they show flower, when they are fully exposed. Others sow a few seeds in the middle of the space between fruit bushes for about 6 or 10 feet into the brake, but no farther. Thus, being near the outside, they get plenty of air and light, and have, in addition, the shelter of the bushes. In many cases, however, they are now raised in frames and transferred to the open ground in June.—F.

THE FLOWER GARDEN.

ARRANGING BORDERS IN SEASONS.

To have a whole border bright in daily varying succession for a given time would be, I apprehend, a temptation to many to adopt this system of arrangement. It has withal many solid advantages, and a few of these I here note down, observing that our border, which may be called strictly a spring and partially an autumn one, has given us much instruction and enjoyment. However circumscribed the garden, it must have varied aspects, and to select the best for the particular wants of each plant is the first step; then collect together those of the same requirements, and one system of cultivation suits the whole. It is merely carrying outside the plan of indoor classification—stove, intermediate, and greenhouses, the shelf for succulents, the shady corner for Ferns. Without making our gardens into nurseries, or giving them the formal appearance of a botanic establishment, I do think a somewhat more systematic arrangement would be a gain for amateurs, as they would lose fewer plants, and economise labour. How often when a plant is received a vacant spot is sought for it, and there it is put for no other reason than that this empty space exists. Overcrowding in all departments is, without exception, the rule in small gardens. By arranging them in seasons, some progress would be made towards remedying weak points in the way of disposition. A border facing the north suits well for a spring garden, and a few trees in the background, of light foliage (Birch, Willow, Poplar), merely prolong the flowering of the Primulas, &c., by the thin shade they give in spring, and do more good than harm in very hot summers, when their leaves are fully out. One learns much while collecting the spring-flowering shrubs and plants, and the quest after some particular variety is very fascinating; great, also, is the satisfaction of having hunted it down, and of selecting the best variety, or, at least, that one which does best in your border; but, as seasons go on, withdrawing duplicates and such individuals as will not thrive must be done. You may be told to renew such year by year, and to keep to your plan of having every plant procurable in that season border; but this is wrong. It is a trial to part with *Menziesia impetrifolia*, *Polygala chamæbuxus*, *Daphne Cneorum*, *Dracocephalum altaense* of finest blue, *Primula integrifolia marginata intermedia*, *Trillium grandiflorum*, *Iris tuberosa*, *Narcissus Bulbocodium*, *juncifolius*, *Scilla bifolia rubra*—a long list, possibly, but your border will still be quite full, and the excluded plants will thrive in other spots of the borders. I would like well to have a spring rock garden. Until one sees how plants do thrive luxuriantly in their stone compartments, as arranged by Mr. McNab in the Botanic Garden of Edinburgh, where soil and aspect, shelter and drainage are all provided in due proportion to suit each tribe of plants, one has no idea of the true character of scores of beauties, unless one has had the good fortune to see such in their native habitats. No crowding or intruding on each other need ever arise, and Alpine treasures are there in abundance. But one cannot have everything, and we are well content with our border on the flat, and make the best of it. Although during spring that season's border has a profusion of flowers, during the next eight months it is positively devoid of them, and this is one of the greatest advantages of the plan, as one comes to learn what beauty there is in a healthy flowerless border. In July I have stopped to admire a group of the following: *Pæonia*, *Iris*, *Saxifraga cordata*, *Anemone sulphurea* (in feathery seed), *Orobis angustifolius*, *Waldsteinia geoides*—a plant which always pleases me from its different shades of green in the young and old leaves, which are also of interesting texture—and the grey deciduous *Sedums* of completely different forms. We have our borders arranged in rows for convenience of hoeing, and to know exactly where each plant is; but I know some prefer to plant their borders in groups, and the effect is perhaps less formal than it otherwise would be. The autumn border can only be partially so, for to have berries then, we must have had a spring of flowers; but we have collected such subjects as *Euonymus europæus* (Spindle tree), Privets, black and yellow-berried, and the autumn flowering one, *Ligustrum japonicum*, Crabs, *Cotoneaster* (we hope to get these into pillars and standards), *Pernetia*

(three sorts), *Leycesteria formosa*, *Escallonia macrantha*, *Myrica caroliniana* (for the autumn tints), old-fashioned and despised Roses that bear hews, the single white, only to be seen in cottage Kale yards (the double variety of which is considered the White Rose of Jacobite days), Scotch Roses with bunches of black fruit; *R. ferox*, with spiny stem; Rose of Sharon, some quite thornless and bearing very long hews, and others nameless to us, but all bearing fruit; Hollyhocks, *Helianthus*, *Phloxes*, *Asters*, *Lilies* (to be cool), *Rudbeckia*, *Chrysanthemums*, *Carnations*, *Pentstemons*, *Fuchsia*, *Scabiosa caucasica*, *Anemone japonica* (three sorts), *Spiræa callosa-alba*, *Snowberry*, *Marigolds*, and a number of plants that are not like these, consisting of many varieties. Brambles are trained up the Apple trees, *Rubus laciniata*, *reticulata*, *biflorus*, on whose white bark can be written its name and date; but I must own they all prefer to fruit on the wall. Mistletoe is on the Mountain Ashes and Crabs. Each February, I go round and smear suitable trees, so as to have this interesting parasite in all stages of growth. *Bryonia*, *Tamus*, and a Hop twine up the trees. The autumn border also faces the north, and thus prolongs the flowering of many species. *Asters* we grow in both our south beds to have them early, and in the autumn and north beds to spin them out. We cannot have too many *Asters*, and yearly add to our collection, weeding out as we pick up more attractive varieties. In the autumn border are introduced herbaceous Poppies, *Delphiniums*, tall *Campanulas grandis*, *pyramidalis*, *Van Houttei*, as there they form a succession reserve crop to those in the mixed south borders. All good useful plants should be grown in different situations. Their season of flowering can thus be prolonged for from four to six weeks. Lily of the Valley, Violets, and successive sowings of *Mignonette*, and other annuals, are grown in beds with this object; but a small garden cannot have beds of all that the owners would like to have. But, if you have a duplicate, look about for a warm and early, and a cold and late spot, and set one plant in each place. Our rule for these borders is to have only permanent plants in them. Thus Dutch Bulbs (so called) are excluded from the early border, and *Gladioli* from the late one. Annuals and biennials, with the exception of *Honesty* (purple and white) and *Marigolds*, from both. To ensure success with such borders, thorough working and preparation of the soil are essential, and not a day should now be lost, as the long storms have thrown such work behind hand in many districts.

F. J. HOPE.

Wardie Lodge, Edinburgh.

Different Kinds of Crocus.—Your correspondent "P." in his interesting list of bulbs now in flower in Mr. Barr's trial grounds at Tooting, gives *reticulatus* as a synonym of *Crocus susianus*. The true *Crocus reticulatus*, which I procured last spring from the neighbourhood of Trieste, is a white Crocus, striped with purple on the outside. In bloom it closely resembles *C. biflorus*. The bulb, of course, is totally different, and may at once be known by its conspicuously reticulated coat. I have reason to believe that till last year this species had been for some time lost to cultivation. Your correspondent also states that Mr. Barr has *C. hadriaticus* now in bloom. The true *C. hadriaticus* is an autumnal species. It blooms with me in October and November, and has long been out of flower. From the description, I have no doubt your correspondent alludes to *C. Weldeni*, Gay (possibly *C. biflorus coerulescens* of Herbert), a very pretty species, now just coming into bloom with me, and of which I think I gave Mr. Barr a few bulbs a year or two since, under the name of *C. variegatus*. It was so labelled by M. Max Leichtlin, to whose kindness I am indebted for the bulbs I possess. I have also received it from a correspondent at Trieste. The true *C. variegatus* is a variety of *C. reticulatus*. I have two varieties of *C. Weldeni*, one with pure white flowers, and another with the petals much suffused with bluish-purple. This latter I received as *C. dalmaticus*. I earnestly beg all sojourners and travellers in Oriental lands to send me bulbs of every Crocus they meet with. We have yet much to learn about this beautiful genus. I am determined, if possible, to grow every known species.—H. HARPUR CREWE, *The Rectory, Drayton-Beauchamp, Tring*.

Hepatica Barlowii and Cyclamens at Heatherbank, Weybridge.—May I call the attention of the admirers of spring flowers to the merits of the old, but not enough cultivated, *Hepatica Barlowii*? Besides the exquisite beauty of its mauve tint, the great length of its flower-stems make it show well up from the ground and in a bouquet. Our bed of hardy *Cyclamens* of many colours is now in full bloom, and, though quite unprotected, the severe frost of last night has had no effect on the blossoms.—GEORGE F. WILSON, Feb. 6.

DATE PALMS GARLANDED WITH PASSION-
FLOWERS.

WE are ever apt to follow in an old groove rather than strike out a new path for ourselves, and this is nowhere more apparent than in the planting or arrangement of our conservatories or winter gardens. The conservatory ought to be a beautiful indoor garden, containing as much natural beauty as is compatible with its necessarily artificial surroundings. Instead of this, it is, in too many cases, but little better than

a glass box, which is periodically refilled with decorative plants as required. This involves a large amount of trouble and expense, and is a great drawback to the amateur cultivator who attends to his own plants, and who is perfectly bewildered amongst a collection of flower-pots, decaying tubs, and a host of dusty and half-starved plants. Planting out does away with much of the extra trouble involved where repotting and watering have to be regularly performed. In many conservatories, both public and private, that are already planted with bold and characteristic vegetation, there is one element of beauty familiar to all who have seen the primeval forest in tropical or inter-tropical lands, or who have attentively read the graphic descriptions of tropical landscapes and natural gardens by the late Rev. Charles Kingsley, in his realistic letters from the tropics, or in his equally interesting book, "At Last." We allude to climbing plants, creepers, and trailers, as seen at home. Our treatment of these in our conservatories or indoor gardens affords us an excellent example of how we pursue the beaten

track, and still festoon the crystal roofs and domes of our plant houses with these most graceful of all plants, thus placing them where they have scarcely any chance of rendering their peculiar style of beauty conspicuous. Climbing plants under natural conditions have no such supports, but cling to other stouter, though scarcely less elegant, forms of vegetation than themselves; and the happiest way of employing them as decorative objects is to take advantage of this fact by planting them naturally in our plant-houses at home. Many tree Ferns and

Palms, Musas, and other naked stemmed forms of vegetation are rendered still more elegant if artistically draped with some of the countless forms of climbers now available for the purpose here indicated. At p. 33 of THE GARDEN, Vol. VII., is an excellent descriptive account of Passion-flowers, Ipomœas, Clematis, and numerous other beautiful plants, that would be all the better if trained in the way here indicated, that is, in houses that are light and well ventilated. Asparagus, Myrsiphyllum, Dictyopsis, Gloriosa, Fittonia, Gourds, and many other climbers of moderate growth, are eminently suitable for the bare stems of Cycads, tree Ferns, and dwarf Palms, as many of the Arecas, Seaforthias, and Chamædoreas. Even in damp, dark, and shady houses we have an abundant supply of dwarf-creeping Figs, Pothos, Selaginellas, Fittonias, Grasses, and Vines, and other foliage plants, which may be used in the manner here indicated with excellent effect.

Date Palms garlanded with Passion-flowers.

THE DATE PALM
IN BAGHDAD.

THE strip of alluvial land lying between the Arabian desert and the tableland of Persia and watered by the Euphrates and the Tigris, was once the garden of the world. In a communication made to the Linnean Society, respecting its present flora, by Surgeon-Major W. H. Colville, the writer has the following remarks on the cultivation of the Date Palm, for which this province is celebrated:—The only Palm in this country is the Date; but whether or not it is indigenous is a matter it would be useless to inquire into. The only place in which it could live a season in the wild state would be on the marshy border of some oasis in the desert, or near such a place as Busreh, where the ground would be watered by a tidal river. Here-

abouts a wild Date would be a greater curiosity than a wild camel; for it could not possibly exist with the scanty rain that falls. The natives, although they understand pruning and grafting, are careless in their cultivation of fruit trees generally. They never touch the Apple, Pear, Mulberry, or Apricot, but let them grow on, only giving them water. The Date tree, on the other hand, they have made quite a study. I shall give, as concisely as I can, the information I have gathered on this subject; for I am surprised to observe that even in the north of India, where experiments on the Date are carried on, more correct knowledge as to its

cultivation would appear to be required. In this province the Date tree is never grown from seed. Occasionally, it is true, a Date tree will be pointed out that has sprung from a chance seed and is suffered to live; but this is a rare curiosity. Till it is one year old it is impossible to tell whether it is male or female; and, should it be recognised as female by the leaf, a still longer time must elapse before it bears fruit. As a rule, it may be expected to be worthless, although now and then a good variety has been produced in this way. It is of no use selecting seed for sowing, for no one making a Date grove would ever plant a seedling, but would always take an offshoot. These offshoots spring from the parent tree at the junction of the root and the stem. The parent, itself originally an offshoot, throws out its suckers, one to five in number, but sometimes as many as twenty, from the second year of its independent existence to the time of its bearing fruit. The tree throws out these suckers only at one period of its life; and, should it bear fruit before any have appeared, it never has any at all. If the ground is good, the offshoot may be torn from the tree at two years; but, should it be poor, the shoot must be left attached a year longer. The shoot is a hardy thing, and may be thrown aside for a month after detachment; nay, I have seen some that were partially burned, and have been told that they were still good for planting, and were sure to grow. The shoot is planted in a hole 1 foot deep and the same in width; and care must be taken not to water it more than once in three or four days, else the young roots will rot. During the winter it must be protected from frost by a piece of matting, often for two years; and the earth must also be raked from the root and horse dung put in. At five years the tree produces fruit, but it does not reach perfect bearing until it is ten years old. The Date tree lives from a hundred to a hundred and fifty years; and it is said that some are now in existence two hundred years old, though they do not produce one-eighth of the fruit they bore in their prime. Two male trees are considered sufficient for one hundred females. Impregnation is performed artificially, but great care must be taken to give the dark varieties only a very slight sprinkling of pollen; and, although the light varieties require a little more, that must be sparing also, else the Dates will drop off before ripening. The young trees produce the most luscious fruit; but the Date will not keep or bear packing and transport till the tree bearing it is ten years old. The offshoots are, of course, of the same sex and variety as the parent. The male trees are, so far as is known, all alike; no difference has ever been discovered in any part of them, and no change has ever been detected in the fruit of any one female, although the males are used indiscriminately for impregnation. There are about a hundred varieties of the females, which can be discriminated not only by the fruit, but many of them by the leaf. The best Dates of all are grown at Il Hissah and Shitolah, oases in the desert, where fresh water gushes from the ground in abundance and spreads over the light soil of the desert with its dry burning winds. The next best are from Busreh, where the combined waters of the Euphrates and the Tigris, shut up twice a day by the tides of the Persian Gulf, overflow their banks and supply the trees with slightly brackish water. The soil in that neighbourhood is alluvial and saltish, and the air hot and moist. Although the Baghdadee sturdily maintains the excellence of his Dates, there can be no doubt that they are not equal, either in quality or quantity, to those grown further south; and the most luscious varieties, those with smallest stones and presumably from the most delicate plants, are not found here in so large a proportion as elsewhere. Baghdad, indeed, in lat. 34° N., is within a degree of the most northern limit of the Date. The variety Zadie produces the heaviest crops, averaging 300 lbs. weight to a tree. Each place has its different taste for Dates. Baghdad prefers the Sukri and Khustawieh, which is the highest crop of all. Constantinople imports the Zadie, packed in skins, and India the Khaderawie, Sair, and Brem, in baskets. These are shipped at Busreh, and are varieties not liked in Baghdad.

The Huon Pine (*Dacrydium Franklinii*).—This is perfectly hardy here. We have two trees of it which were planted in 1857, one of which is 10 feet in height and 16 feet in diameter, and both are excellent specimens. Has any of your correspondents larger plants of this Pine?—W. NANSAWEN, *Coldrick, Menheniot, Cornwall*.

Brickwork the Best Setting for Boilers.—However objectionable brickwork may be for a boiler setting—and Mr. Thomson (see p. 95) appears to condemn it thoroughly—there is no material with which I am acquainted which better answers the purpose; boilers when not set in brickwork soon part with their heat, which is lost in the stoke-hole; but when encased in good solid masonry, the bricks absorb and retain the heat that is thus lost. At the boiler trial at Birmingham one set in brickwork had its fire drawn out, and the doors and dampers thrown open, yet the water which it contained boiled for six hours afterwards—a fact worthy of note, inasmuch as I do not think a detached boiler could have retained its latent heat so long, especially as the weather at the time was anything but favourable. As to the position of the flow-pipes I shall refrain from making any remark until I have completed some experiments which I am making with a small boiler fitted up as your correspondent has suggested.—J. DEARDS, *Harlow, Essex*.

GARDENING FOR THE WEEK.

Flower Garden and Pleasure Grounds.

Ornamental evergreens and deciduous trees, on lawns and elsewhere, are not unfrequently disfigured, and sometimes irretrievably ruined, by the splintering of their boughs during high winds, when the boughs are rendered heavy by rainfall, or by a mass of snow adhering to them. Such species as the Cedar of Lebanon, and many of the Pinuses, are, from their style of growth, particularly liable to this misfortune, which timely attention, however, might in many instances avert. Before we are visited by the gales which usually accompany the vernal equinox, it is advisable to give attention to this matter. The large and heavy branches of trees such as those alluded to, naturally assume a horizontal position, and must consequently exert a very considerable strain upon that part of the tree where they leave the stem, or trunk. An examination of these parts will not unfrequently disclose rents or fractures of the bark, which, however slight, may nevertheless admit water; and if this be so, the evil will gradually increase, until the time arrives when the branch falls to the ground, sometimes with little or no warning, and then it is discovered that the mischief has been gradually progressing, probably for years. All that can be done under these circumstances is to smooth the unseemly wound, conceal it as much as possible from view, and exclude air and moisture by a covering of sheet lead, or zinc, which should be painted of a colour similar to the bark of the tree; or the place may be covered with Portland or Roman cement. Prevention is always better than cure, however, and such casualties may often be averted by covering anything in the form of a rent or fissure, however slight it may be, with sheet lead, zinc, or cement, in order to prevent the entrance of water; while support should also be given to heavy boughs by the use of strong hoop-iron or chains with screws and bolts if found necessary. And this may generally be done without being rendered conspicuous or at all unsightly, as supports placed upon the ground would necessarily be. If not already done, finish as soon as possible the transplanting of deciduous trees and shrubs, whenever the weather is favourable. Many planters, however, prefer the month of April for transplanting Hollies and evergreens of all kinds, and this, during most seasons, is generally accomplished with success. But such exceptionally dry seasons as that of 1874 proved exceedingly trying, particularly on light soils, to spring-planted trees and shrubs, and necessitates a vast amount of labour for watering; so that, taking one season with another, October may be safely considered as the best month for transplanting trees and shrubs of all kinds. The weather, until the last day or so, has been mild for the season, and some of our early spring flowering plants, such as the Snowdrop, Violet, Aubrietia, Forget-me-not, &c., are already beginning to be attractive. The quiet beauty of these early harbingers of spring generally commands an admiration which is not always accorded to their more gorgeous successors; and, in order to render the enjoyment of these early-blooming plants as complete as possible, the bed and borders containing them, as well as the walks and greensward by which they may be surrounded, should all be kept in the best order possible. The margins of walks and beds upon Grass should now be cut or edged, but, before this is done, all inequalities in the surface of the turf should be rectified, should any such exist; and the turf near the walks should be rendered as solid and firm as possible, whilst the margins, by the aid of pegs and lines, should be defined with the greatest accuracy.

Gravel Walks.

To keep gravel walks in good order, a slight coat of gravel should be given at least once a year; and this may either be done now, or may be deferred until the end of May, when it should be applied as soon as the bedding-out for the season has been completed. Before this is done, however, it may frequently be found necessary to remove a thin portion of the surface of the walks, which will sometimes be found to be discoloured by exposure to the weather, or green from the presence of some species of Moss; but this will, of course, depend much upon the situation of the walks and the nature of the gravel which had been used.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Roses.

Those who wish to improve their Rose beds and plantations should, as soon as the ground is dry enough, give the beds a good dressing of rotten dung and fresh loam. If a little bone dust can be procured, its application will greatly improve the quality of the flowers in the flowering season; bone dust, used judiciously, is the finest manure for Roses, but care must be taken not to use it too strong. I have generally dusted it over the ground as I do lime for killing insects, and this spreads the manure evenly over the beds and borders; they should then be forked over to a depth of 5 inches, or deeper still if

it can be accomplished without disturbing the plants so much the better. Take away all suckers while digging the beds, as they are more readily got at, without disturbing or injuring the plant when the ground is being turned over. Select a warm corner for Tea Roses if fine summer flowers are required, and trench it well, adding plenty of fresh loam and rotten dung, so as to plant a few pot plants out towards the end of this month for summer flowering. Fine exhibition blooms can be obtained from plants turned out in this way, and they can be lifted again in October for pot culture if required. Tie and train all pot Roses coming into flower. I recommend the young shoots of the Hazel for training Roses, as they blend more with the foliage than painted deal sticks, and are much cheaper. If one flower opens before the other when small plants are wanted for decoration, it is advisable to use a shade over the earliest blooms; a piece of brown paper or common newspaper answers the purpose, and is quite sufficient to exclude the sun's rays from them.—H. G.

Bouquet Flowers.

Covent Garden and other markets are now well supplied with cut flowers, amongst which may be enumerated Azaleas, Bouvardias, Camellias, Carnations, Cyclamens, Eucharis, Euphorbias, Gardenias, Heliotrope, Heaths, Lily of the Valley, Mignonette, Nemophila, Pelargoniums, Primulas, Roses, Snowdrops, Stephanotis, Violets, white Lilac, &c. With such a stock many effective arrangements may be made. Among the most useful flowers at this season for mounting hand bouquets are the different varieties of Cineraria, numbers of which are brought to market in a cut state; both the blue and rich purple tints, to be found amongst these plants, are most effective; the blue looks best mixed with white and green only, but the effect of the purple is enhanced by being associated with Orchids of a lighter shade, mounted so as to stand up above the other flowers; and, if a few spikes of Lily of the Valley be employed, a light and charming effect will be produced. Snowdrops, too, are well adapted for bouquet making, as they are much less expensive than Lily of the Valley, and answer the same purpose; indeed, they last fresh much longer than Lily of the Valley. Charming bouquets may be made with blue Nemophila, pink Pelargoniums, different varieties of white flowers, and Ferns; the best shade of pink Pelargonium for associating with the light blue of the Nemophila is the old pink Christine, so much employed for bedding purposes.—A. HASSARD.

Indoor Fruit Department.

Vines.—Turf stored in autumn for forming Vine borders may now be chopped up with a spade. This should be done under cover, if possible; if not, the soil should be protected from wet after it is cut up. This is easily done by throwing a tarpaulin over the heap. Where new Vineries are to be filled, the turves can often be wheeled into them, and cut up and mixed on the spot where it is to be used. If a sufficient stock of soil has not been obtained, the remainder may be procured now. As there is now little time for the Grass to decay, as much of it as can be got hold of should be cut with a scythe from the top spit before removing it. When this has been done, the turves may be cut about 15 inches square. The depth to take the soil should depend on the quality. If it is very old pasture, the fibre will be found to descend for 6 or 8 inches from the surface. If it is of comparatively recent formation, the suitable stuff may not be more than two inches thick. When cut up, the pieces should be about 2 inches in diameter. If any wireworms are observed, they should be destroyed before the Vines are planted. Kale stocks, with the leaves taken off, and rammed into the heap of soil, trap them effectually, and generally clears them out in a short time. Leave the stocks as long as possible, that they may penetrate well into the centre. Where a choice of soils can be had, the most calcareous should be taken, preferring that which contains a little clay rather than sand. See that the heat in the beds of fermenting material, which is giving warmth and protection to early Vine roots, does not decrease; and prevent this by working in fresh matter. This must not be neglected, although the fruit may be set.

Pines.—For these a lean-to house is the most convenient and servicable at all times and for all sizes of plants, excepting small suckers, which can be placed in low frames. The large houses should be constructed with a pathway up the centre, and a bed at the back and front. They should be at least 9 feet wide, to allow 3 feet for each of the beds, so that it may hold two rows of large plants each, and be divided by a 3 ft. pathway. Where the boiler can be got far enough down, it should be placed so as to direct a blow pipe up the bottom of each bed. The bed should be 2 feet deep, and the bottom of it, above the pipes, should consist of perforated metal plates, similar to those often used for the centres of pathways, when they are laid with grating. The heat passes much more freely through this bottom than through thick flags, which are much used; two flows and returns are sufficient for

heating the atmosphere of such a house; they should run along between the upright front and the front row of plants. Ventilators should be placed at both top and front to regulate the quantity of air. The height should be no more than will permit a person to walk upright, as it is not desirable to have the plants far from the glass. In such a house, those in fruit can be placed in the front bed, and the successional ones at the back, or *vice versa*. The back bed should be raised a foot or more above the level of the front one; this keeps the plants near the glass with the rise of the roof. The sucker frame may be provided with a single bed and heated at the top and bottom in much the same way as the large stove. When the panes of glass are 10 and 12 inches wide the plants are much benefited by light, and I prefer this width to the narrower ones, not only for glazing Pine-stoves but for all other structures.—J. MUIR.

Hardy Fruit.

Now that the weather is more favourable, planting operations should be no longer delayed. Those who have not completed their lists of Pears will do well to add Beurré de l'Assomption and Madame Treyve, both of which fruited here last season for the first time. The former may be described as a large Williams' Bon Chrétien, ripe at the same time, quite equal to it in quality, but without the musky flavour peculiar to that variety. Madame Treyve is also an early variety, very large and melting, and worthy of a place in all collections. If late ripening kinds are in request, the following are all excellent in quality:—Bergamotte d'Esperen, Easter Beurré, Josephine de Malines, and Ne Plus Meuris. All newly planted fruit trees, of whatever kind, should have thick mulching, the value of which cannot be over-rated. The pruning of all kinds of fruit trees may now be safely effected; indeed, should be finished out of hand forthwith, for, to say the least, it is unnatural to be cutting back a tree when the buds are ready to burst into full blossom. Sometimes pruning is deferred as late as possible, under the impression that early pruning induces early flowering, and, consequently, greater liability to injury from late spring frosts. In order to prove the correctness of this theory, a year or two ago, part of our Peaches on a south wall were pruned in November, and the others in February; both came into flower exactly at the same time, and, though both were good, those pruned the earliest broke, flowered, and set their fruit with greater regularity than the others. Late pruning is only to be recommended where birds are troublesome, and then only in the case of Gooseberries and Plums, the buds of which they are very fond of. In pruning Apples and Pears, save the cuttings of any kinds that it is desirable to increase by grafting, which must be done in March. The cuttings will keep perfectly if placed in the ground on the north side of a hedge or wall. Protection of some kind or other for fruit trees on walls should now be ready. Here, the walls have a coping projecting 15 inches, under which is fixed the frame-work for blinds made of scrim canvas, and, with the aid of rollers, pulleys, and strong sash-cord, the whole can be covered or uncovered in a few minutes. Such blinds are not only useful for protection when the trees are in flower; but, on sunny days at this season can be drawn down to retard flowering. Where, from the expense, such coverings are out of the question, procure long poles and place them against the wall at an angle of 45°. To these fasten hay or straw-bands lengthways, and 6 or 8 inches apart, for the admission of light and air. Two or three thicknesses of common garden netting are neater and better than hay-bands. A neighbour of mine, who has the use of large Birch plantations, most effectually protects the whole of his wall fruit with large flat branches of these trees, always selecting those with the most spray. He simply rears them against the trees, slightly fastening the thick ends in the ground. Evergreens, if they are to be had, will answer the same purpose.—W. WILDSMITH, *Heckfield*.

Kitchen Garden.

During the last few weeks the weather has been more favourable for pushing on outdoor operations and bringing up all arrears in digging and trenching. As every day will now bring its work, the exercise of forethought and diligence will be necessary in order to enable us to keep pace with the season. Plant out Bath Cos and other hardy kinds of Lettuce that have been wintered in sheltered borders; a single row at the foot of a south wall, between the fruit trees, will not do much harm, and in such a position they will turn in early. All warm sheltered spots may be utilised in this way for forwarding some non-exhausting crop for which there may be a demand. Sow the main crop of Parsnips in drills 15 or 18 inches apart; it should, however, always be borne in mind that unless the surface of the ground be in a mellow friable condition, it will be better to wait a few days. To plant or sow anything when the land is wet and unsuitable is very often labour in vain. Of course, the comparatively small space required for forwarding early produce can be so altered in texture and character by heavy and frequent

dressings of burnt earth and leaf mould as to be practically workable at any time; but with the larger sowings of the main crops, the case is different, and some soils that are of a retentive nature are in some seasons peculiarly difficult to manage, and after the snow and the mild damp weather of January, the land is not in so favourable a condition for planting and seed-sowing as it often is at this season; hence waiting and watching will be the best course to pursue. Take advantage of a favourable opportunity to sow in a warm sunny spot a few seeds of Snow's Winter Broccoli, Cocoa-nut Cabbage, Walcheren and Veitch's Autumn Cauliflower, Brussels Sprouts, and Green Curled Kale. Where any of the above were sown in autumn, they will now require to be pricked out, so as to have strong hardy plants to put out early. This is a good season for making new plantations of Rhubarb by dividing old roots either into single crowns or larger pieces. Do not plant too deeply, especially if the land be heavy. To obtain fine produce, Rhubarb should be divided and transplanted at least every four years. My own practice is to take up the four-year-old roots every year, divide a few roots for making a new plantation of the same extent elsewhere, and force the remainder. Unless there may be some special reason for grouping the Rhubarb into one plantation, single rows all across a quarter will be found more productive. A few of the earliest roots may now be covered with tubs or large pots, to shelter and forward them. Old cement barrels, with one end out, are cheap and handy for this purpose; and, when Rhubarb is covered up in this way, it not only comes earlier, but is of a beautiful colour and delicate flavour. If not already done, Globe Artichokes should be uncovered, leaving some of the shortest material as mulching round the base of the plants; fork between the rows to admit the air into the land, which improves its texture and condition. In very warm positions sow a few early Horn Carrots and Radishes. Mustard and Cress may be sown in quantities, as required, under hand-lights at the foot of a south wall or screen. In the forcing department, successions of Rhubarb, Seakale, and Chicory may be introduced to the Mushroom-house or forcing pit. The latest bed of Seakale should be covered with pots, if not already done, and a good covering of leaves placed over it—more, however, with a view to blanch than to force; therefore, there need not be depth enough to ferment. Late Seakale is often as desirable as early, and it may be obtained in this way as late as it is possible to have it; the leaves should be covered with long litter, to prevent them from being blown about. Seakale beds should always be outside the walled garden, where it will not become an eyesore.—E. HOBDAV.

MILDNESS OF THE WINTER IN THE SOUTH OF IRELAND.

WHILST gardeners, both in England and Ireland, have been put to their wits' end to save their plants in pits from frost, we have been almost free from its withering influence, and, instead of snowball and ice sports, we have been getting our usual winter supply of rain, not having been twenty-four consecutive hours without it for five weeks, although it has not been so heavy as we usually have it; 6.25 inches only have fallen in January. As it may interest some to know the results of the mild weather which we have been experiencing, and its influence on vegetation, I will just enumerate a few plants which we have in flower. The *Acacia affinis*, or Green Wattle, growing on south-east and south-west aspects, has been in flower for several weeks, and is still covered with hundreds of beautiful clusters of golden blossoms; *Clanthus puniceus*, or Glory Pea, a plant too often seen in a half-starved, red-spider-eaten condition, is growing here on a south-west wall in perfect health, and covering a space 30 feet long by 10 feet high; it would have easily covered twice as much wall had there been room. It has thousands of long racemes on it just ready to burst into flower. Surely this plant is worthy of more extended cultivation than it receives, inasmuch as it would well repay any little trouble which it might require in the way of protection in localities where it would not otherwise succeed. Camellias on walls of different aspects have been in flower for a long time, and *Cytisus atleeanus* is now covered with yellow blossoms. It has been growing out here for many years, and has a girth of 18 inches in the stem; I have also a large bush of a *Colletia*-like plant in flower, as well as the singular *Colletia bictonensis*, which is indeed past its best; also the pretty and fragrant aquatic *Aponogeton distachyon*, which has been in flower for months, and is still throwing up many blossoms. Fruit trees have likewise been influenced by the mildness of the season. Pears are ready to burst their flower-buds, and in some cases the bloom is quite expanded, while all other fruit trees are in a similarly forward state; Gooseberry bushes are quite green, but will, I fear, suffer from our usual cold high winds in March.

Fota, Cork.

W. O.

THE INDOOR GARDEN.

CALADIUM CULTURE.

THE Caladium is undoubtedly one of the most ornamental and attractive of our fine foliaged stove plants, and few convey a better idea of the luxuriance and splendour of tropical undergrowth to those who have never been in tropical regions. Some years ago Caladiums, like Begonias of the Rex section, were the rage; and, like most things in which people indulge to surfeiting, they have fallen off in popularity, their easy culture helping, no doubt, to affect this as much as anything else. Such a varied assortment of magnificent decorative subjects are not likely to be lost sight of, however, by those who have any appreciation for plants that are as useful as they are highly ornamental. Take the noble Caladium esculentum, for instance, which I have grown with leaves almost 6 feet in depth and 3 feet across at the lobes—no plant surpasses it for furnishing, in some situations, in halls and drawing-rooms. I have known it to be so much esteemed for such purposes that artificial specimens, copied from the natural plants, were made to take the place of the latter when they were not to be had. To have the plant in its beauty it must be grown with some care, and not, as it usually is, in stoves, far from the light, and where the leaves have to struggle up through a crowd of foliage upon spindly stems that cannot stand erect upon their own responsibility. Years ago one of the most select and best grown collections of Caladiums was to be seen at Dalkeith, in the Victoria-house there. The plants were grown with plenty of room and plenty of light, and, instead of plants with lanky leaves trailing over the sides of the pots, they were erect and symmetrical, the tints of the leaves well up, and the general development perfect. At that time we were restricted to the parents of the present numerous race, many of which appear to me to have run into each other too much to deserve a character for distinctness. The favourites were esculentum for a background, violaceum and others; then came bicolor splendens, picturatum, Chantinii, Belleymei, and the dwarf little argyrites, so well adapted for curb-stones and shelve edgings. The Caladium is not difficult to grow to perfection if it is treated liberally, and care taken to prevent the plants getting a check at any time, which is almost certain to arrest the development of the leaves before they have attained their full size, and no satisfactory growth is made after that. The roots should be shaken out carefully about the beginning of March, and the largest selected and potted, two, three, four, or more in a pot, according to the size of the bulbs and the variety. Large single roots of *C. esculentum* will sometimes require a 12 or 14-inch pot at the first; while the little argyrites, when grown for neat specimens, will only want a 3 or 4-inch pot for a number of its little bulbs the first shift. The pots should be carefully crocked, but not too deeply, and a soil consisting of two-thirds light turfy loam, one of well-rotted leaf-mould and cow-dung, and a considerable addition of silver or common clean river sand, according as the loam is light or heavy, will suit them well. The bottom layer of soil may be made moderately firm with the fingers; but, on the whole, they should be rather loosely potted, seeing that long fleshy roots, that give massive leaves and not flowers, are what should be encouraged. After potting, they should be plunged in a bottom-heat of about 75°, to begin with, in a stove or warm pit, and very slightly watered at first—or, indeed, not at all for a time, if the bulbs have been dried off during the winter, in which case they are exceedingly apt to rot off as soon as committed to the moist soil again. The roots will grow faster than the leaves at first; but, when the first leaves do appear, the plants may be copiously watered, for, though the Caladium is not an aquatic, it delights in abundance of moisture. As regards top-heat, a general and moist stove temperature will suit them well, according to the season of the year, and they must be kept in a good light, not far from the glass, and subjected to a free circulation of warm air, and shaded carefully on sunny days with thin canvas. Before more than the first rudimentary leaves have been formed, the plants will require a second and final shift; and much depends upon doing this at the proper time, as, if the roots are allowed to get at all matted before potting, the plants will receive a check, which will sadly interfere with the size

and beauty of the leaves. By turning a plant out of the pot, it will be seen how far advanced the roots are; and, when they are found pretty numerous at the sides of the ball, they may be shifted. Each variety should receive a shift into pots from 1 to 3 inches larger than the first ones. The soil should be of the same description as before, and have the chill taken off before using it. In potting, see that the roots are not disturbed in the least—only remove the crocks. Pot carefully, leaving plenty of room for watering, and restore the plants to their former quarters, until they have got established, when they may be moved into the plant-stove or house where they are to be displayed during the summer. Here they must not be neglected, or be allowed to become dry or shaded; they must have room, light, and air, and frequent waterings with weak liquid manure. With this treatment they will grow apace. Any flowers they throw up must be pinched out at an early stage, faded leaves cut off, and everything done to keep up and prolong a vigorous growth until the plants show a natural disposition to go to rest in autumn. From this period till the plants are started again in spring, some care is wanted to keep the roots from perishing with dry rot. It was once recommended to dry the roots off entirely during winter, letting them remain in the

Caladium Belleyi as a Vase Plant.

pots of course, and I believe this practice has caused the loss of many a valuable collection. Roots so preserved are more apt to decay than usual, and, as I said before, they are in great danger of rotting after being potted-off in spring. I knew of one fine collection that was nearly extinguished by this treatment, though the roots were dried gradually and kept on a stove shelf all the winter. More or less decay will happen, perhaps, under any circumstances, but I never knew it occur to any serious extent where the roots were never dried at all, but simply kept in their pots in some corner of the stove, and kept moderately moist, as we may suppose they will be in their natural habitat.

J. S. W.

Tree Carnations.—No time must now be lost in obtaining cuttings of tree Carnations; for, if required for next winter flowering, they must be propagated this month; later struck cuttings do not answer for winter flowering. It will be found that Carnations have made some good wood by this time where they have been grown in a favourable temperature. It is as well, after making cuttings, to lay them out for an hour or so before planting them in their pots so as to dry up the wound, and they are not so apt to rot off.—H. G.

ORCHID CULTURE, PAST AND PRESENT.

AMONGST flowering plants that have been introduced into this country for cultivation under glass, there are perhaps none that have attracted more attention than Orchids. The fantastic form of flower in a great number of the species, their exquisite perfume, and the blending of the gorgeous colours of many, together with a general appearance so different from all other plants, at once stamp them as the most singular of Nature's vegetable forms. So far as we can learn, occasional importations took place during the latter half of the last century, and at the commencement of the present they increased; but so little was attempted in giving them anything like the treatment they require that they used gradually to dwindle away. This was not to be wondered at, considering the atmospheric moisture necessary for their cultivation, and the comparatively dry condition in which plant-houses in general were kept, even at a much later date, as compared with the practice of the present day. Forty years ago there were very few collections in the country. Messrs. Loddiges, of Hackney; the Rev. Mr. Clowes, of Broughton, Manchester; Mr. Brocklehurst, of Macclesfield; and Mr. Lyons, across the Channel, who wrote a book upon their culture, were among the first to really study their requirements, and to form collections. The first three exotic Orchids I recollect seeing were the West Indian *Epidendrum* (*Epidendrum cochleatum*), *E. ciliare*, and the old *Bletia* *Tankervillei* (*Phajus grandifolius*). Then came *Cattleya Loddigesii* and the magnificent *C. labiata*. As collections were formed, it was no uncommon thing to see plants from the hot dry West Indian Isles (such as the three first named) associated with the cooler but more moisture-loving *Cattleyas* and others which were gradually brought into the country from the moist shady forests of Brazil. The drier light-requiring plants from the open prairies of Panama and Honduras, such as *Peristeria elata* and *Schomburgkia tibicinis*, *Dendrobium nobile* from China, other *Dendrobiums* from the hot and moist regions of India, and even the New Holland *Dendrobium speciosum*, were all made to conform, in a certain measure, to one uniform treatment. The result was that, although some flowered regularly, others never flowered at all, though often continuing to grow freely. Later on, in the manufacturing districts, there were numbers of those who shipped goods to India, China, South America, and the West Indies, who used to receive plants from their agents in those countries. These were usually consigned to a Pine-stove or early-forced Vinery, in many cases doing remarkably well; and a number of these plants, such as the East Indian *Aërides crispum*, might have been met with, as stout and vigorous as could possibly be desired, after being in the country for a number of years. Afterwards the plants from the different countries were in a measure cultivated separately, or, rather, such as required more heat and moisture were separated from those that wanted a cooler drier atmosphere, with more light and air. Then such species as the Dove plant (*Peristeria elata*) and the *Schomburgkias*, that had hitherto done nothing but grow when kept too close and without the light they required to solidify their growth as it was formed, were induced to bloom freely. Thirty years back the cultivation of these plants began to spread rapidly, and shortly afterwards were to be seen in many places in the country, as well as on the stages of the various horticultural exhibitions, plants that have never been surpassed, and some species that have not since been equalled. The dreaded disease known among the growers of Orchids as "spot" was little, if at all, known at that time, although the nature and requirements of Orchids were then in some measure not generally known. The disease has since been traced to mistaken ideas in their cultivation. It was no uncommon occurrence to see a man grow a number of plants successfully in a particular house, and be unable to manage them nearly so well if he removed them to another. It was thus evident that the accident of position, form, or light-giving properties of the house, separately or combined, had more to do with success than any knowledge possessed by the grower, which ought to have enabled him to adapt his treatment to the difference that existed in the house his plants were grown in.

Heat and Moisture.

Orchids will for a time bear more heat and moisture than are necessary or conducive to their well-being. This is evident to all who have had experience in their culture, and are observant as to the effects produced by the different conditions under which they are grown. For instance, the beautiful blue *Vanda* (*V. cœrulea*), from the comparatively cool and exposed regions of the Khasya Hills—which, if grown in a high temperature, with little air and light, quickly succumbs—will for years bear great heat if hung up within a few inches of the roof-glass. This plant is only one of many that are similarly affected. The mistake committed in the cultivation of these plants is very easily accounted for. Their high price and comparatively slow growth naturally made cultivators desirous of getting

them on as fast as possible; plants so grown have for a time a better appearance than such as are worked more slowly, making more and larger leaves, and possessing a darker shade of green. Nor do they at once show the ill effects of the treatment, but will go on for two or three years carrying their fresh deceptive appearance, getting the grower into a "fool's paradise" through the luxuriant green appearance of his plants. This goes on until the mischief—in a great measure irreparable—is done. They begin to show it by sap oozing in patches from the ruptured cells, which afterwards turn black, gradually eating away the leaves, and ultimately extending to the stems and pseudo-bulbs of the plants; after this, when badly affected, they rarely recover, although they may dwindle on for years. On more occasions than one I have been tempted, through low price, to purchase plants that have been slightly affected with this disease, and, by very careful treatment, such as keeping from them everything likely to excite or stimulate more than very slow growth, and cutting away the affected portions, they have in time overcome the disease, to all appearance leaving nothing but a new plant, so to speak, apparently quite healthy. Yet, I always found that such plants, however well they looked, if submitted for ever so short a time to any excess of heat or moisture, at once showed the disease in the most unmistakable way, giving proof that, although a new plant, as it were, was formed, at present completely severed from the affected parts from which it had sprung, the debility which produced the disease was nevertheless imparted to it, and ready to show itself under the least excitement. As I have attempted to show that this disease is produced by an insufficiency of light and air, accompanied by too much heat and moisture, so in general the shading material used for Orchids is thicker by half than it should be; and to this may be added the fact that the houses in which the plants are grown are not placed in a position to receive, or constructed so as to admit, all the light possible. The plants, again, are too often placed in the houses in a way to give the best effect, instead of being elevated as near the glass as possible, where, in addition to receiving the maximum amount of light, they would be situated where there was a continual motion of the air. I have invariably noticed that the healthiest collections of Orchids to be met with—not the greenest, or that made the largest leaves, but those that flowered the most freely without the barbarous drying shrivelling process often resorted to when at rest to produce bloom in plants whose treatment in the growing season (the proper time to impart to them the capabilities for flowering) had been the reverse of what was calculated to induce this disposition—were those that receive the most light, with plenty of air in the middle of the day, whilst making growth. Of course, this does not apply to exceptional plants like *Miltonias*, that cannot stand much light, but to the generality of the occupants of Orchid-houses, either from the eastern or western hemispheres. When Orchids receive a sufficiency of these two most essential elements, they will bear without injury considerably more heat and moisture. In respect to artificial heat, as applied to the different plants we cultivate under glass, it should be borne in mind that a given temperature—say 80°—applied to any plant in the confined atmosphere of an ordinary hothouse, exerts a considerably greater influence in exciting and forcing growth than the same degree of heat would have upon it in the unconfined open air of its natural habitat. Even the size of the house has a great deal of influence in this respect; the growth-exciting influence of a given temperature in a small house, when closed, is considerably greater than a similar amount of heat when applied to the same plants in a large house also closed. This I have frequently proved by several experiments. Consequently we must bear in mind that, although a plant in its native country, fully exposed to the open air, is subject to certain degrees of heat in the growing season, a lower temperature in the confined space of a glass-house will have an equal influence in exciting growth. That equally great errors have been committed in the unguarded use of moisture in the atmosphere of Orchid-houses, is also evident. To produce the greatest amount of moisture, many contrivances have been resorted to; there is one in particular which, because its influence is continually at work while fire-heat is going, has in no small degree contributed to this excess. I allude to evaporating troughs being fixed or cast upon the hot-water pipes. These are right in principle undoubtedly when not too numerous, or when too many are not kept filled in severe weather, when the necessity for keeping up a strong heat causes far too much aqueous vapour to be generated and to surround the plants; this is far more baneful in its influence than too much at the roots would be, if the pots are sufficiently drained, and the material in which they are grown is sufficiently open to allow of its escape. Some sixteen years ago or so, one of the leading London Orchid growers advised me, when next I was at Liverpool, to call at Hurst House—Miss Willis's place—a few miles out of town, to see her Orchids. I did so the next time I was in the neighborhood, and what I had heard about them conveyed only

an imperfect idea of the size, strength, and vigour of the plants. All I can say is that most of my preconceived ideas of Orchid culture were considerably upset. A description of some of the most remarkable plants, with the position they occupied in the houses and their treatment, will convey some idea of their excellence, and the very different treatment they received to the generality of these plants.

The Hurst House Orchids.

On arriving at Hurst House (an old-fashioned one), I soon found the gardener, who had grown the Orchids up to what they were; his name has escaped my memory, but he was a man considerably advanced in years, painstaking and unobtrusive—one of those individuals in whose company you cannot long remain without feeling a respect for them, through the absence of any disposition to boast of or exaggerate their own doings, even when such were visibly far above the common order. The principal range was composed of some four or five large hip-roofed houses, facing the south; the centre pits of some were filled with Pines and miscellaneous plants. The Orchids, in literal terms, were not a collection, but rather a selection of the best and most effective kinds, from both the eastern and western hemispheres. The houses were heated by very large flues—so far as I can recollect, some 2 feet wide—so large that a person might have crept up them. When a flue is made at the present day, it is in general not half large enough, and so gets over-hot and bursts, without giving off nearly the heat that a larger one would. These flues first traversed the front of the houses; on them were placed loose bricks, and on these rested strong slates overhanging the flues, and covered with sand; and on this stood the plants, which in the front of the houses were all large and grown in shallow pans, many of them 2 feet and upwards across. The front lights were some 5 feet in depth; consequently, except in the case of a few of the tallest, the sun had no direct influence upon them from the roof glass. There was not, so far as I could understand, a particle of shading of any description used, the plants remaining fully under the sun's influence, so far as its coming upon them through the upright front lights. The smaller plants and pendent-growing *Dendrobiums* occupied a broad shelf that overhung the back path in the usual position such shelves are generally to be met with in hip-roofed houses. My visit was in the beginning of May. On entering, the first plant that took my attention, standing on the already-described slate table, was a *Saccolabium guttatum*, some 4 feet high, and nearly as much through. It was a dense mass of breaks from the bottom to near the top, with short leathery leaves, and pushing over thirty bloom-spikes. It was by far the finest plant of *Saccolabium* I ever saw; although not a very good variety, yet nevertheless it shortly after changed hands for, I understood, £100. Near it stood some plants of *Aërides crispum*, 5 feet in height, with every leaf perfect down to the pot—a condition this fine Orchid is seldom seen in, even when not half this height; there were numerous side-breaks on them. Not far from these were several *Phalænopses*, *amabilis* and *grandiflora*, with from a dozen to fifteen short strong leaves to each plant; one of them, in addition to several flower-stems it was making, threw one up from the centre in place of a leaf—not an unusual circumstance, I understood, with these Hurst House *Phalænopses*. Amongst numerous *Aërides* in different varieties (which upon examination were, like these plants in their native country, pushing flower-spikes to every leaf they made), and other plants from the eastern regions, was a *Saccolabium retusum* with double-branched spikes, the longest of which was over 2 feet 6 inches. Not a bad idea of the quantity of flowers it bore may be formed from the fact of the first blooms which it had opened on the top of the spike being dead and fallen off before the point was so far developed as to show the individual flower-buds. Near it were examples of *Saccolabium Blumei*—not so large, but equally vigorous. On the back shelves the plants, although smaller, were as strong. I measured bulbs of *Dendrobium primulinum* over 4 feet in length. In the other houses, similarly arranged, were *Cattleyas*, such as *labiata*, *Skinnerii*, and *Mossiae*; several examples of the two latter, some 3 feet across, were completely covered with flowers, so as almost to hide the leaves. *Oncidium ampliatum majus* was in such size and condition as to be scarcely recognisable, with numbers of other fine plants in equally extraordinary vigour. In the houses where the East Indian plants were grown I had a pretty good clue to their treatment as to air by the state of the Pines, which showed, by their short broad leaves, that they were not stinted for air, which was taken off early through the growing season, and the houses thoroughly moistened at that time, but, in the middle of the day, everything was allowed to get quite dry—the night temperature, and that in the winter, kept considerably lower than usual for these Orchids. The *Cattleyas*, *Lælias*, and similar plants, were as short, both in bulb and leaf, as imported plants. The thick-rooted Indian varieties made comparatively few

roots above the surface of the soil, which was as different from what is generally used as could well be imagined, consisting of a mixture of fine sifted peat and old Mushroom manure, also sifted, with a liberal admixture of charcoal. The plants were kept drier at the roots than usual—no doubt a necessity when grown in such soil; for, if this material had been kept as wet as the ordinary Orchid soil, the roots would no doubt have perished, instead of which they filled the pots almost like those of an *Agapanthus*; but I do not attach much importance to the soil in which they were grown. It was the light, air, temperature, and correct balance of atmospheric moisture wherein the secret of success lay—a success that astonished everyone I ever met who had seen them.

Rational Treatment.

Another individual with whom I have long been acquainted for years grew a small collection of the principal varieties of *Aërides* and *Saccolabiums*. They stood all the year round on a 3 feet wide table, on the front of an ordinary but very light plant stove, facing the south, without a particle of shade to the upright glass, and a very thin coating of paste on the roof. The whole of the lights on the front were hinged at top, and regularly through the growing season were opened every day, directly facing the plants, without anything to break or warm the air before it came in contact with them—a sort of treatment that most regular Orchid growers would have looked upon as sheer madness; yet, although shorter in the leaves, and not so deep-coloured, they carried their foliage, broke up young growths, and flowered in a way that similar varieties with ordinary Orchid treatment never do. But anyone who would try this more natural treatment should either commence with imported plants or such as have been previously grown with more light and air than are generally used; for plants whose every part had been formed under conditions that must of necessity make them much more tender could not be expected to well bear exposure to air and strong light such as described. Respecting these fine Orchids, *Phalænopsis amabilis* and *grandiflora*, how comparatively few there are who continue to keep them going on for years improving and increasing, as they will do when they receive the treatment they require. The secret of continued success with these plants is to keep them hanging as near the roof as possible, with a much lower temperature through the time they are at rest than the country they come from would lead anyone to suppose they would bear. I have in my mind's eye a lean-to house with a northern aspect, in the north of the kingdom, where these plants grow more like weeds than anything else, and yet I know for a certainty that the temperature all through the winter nights is nearer 55° than 60°; and this is by no means a solitary instance of successful culture in these plants. In Orchid growing, to be really successful, the plants should go on continuously increasing and improving, a good example of which is the magnificent *Vanda cœrulea* (see p. 43) exhibited by Mr. Smith, gardener to Mr. Lane, Badgemore, Henley-on-Thames, on the occasion of the Royal Horticultural Society's show at Kensington on Nov. 11. The plant, although not by any means a large one, consisted of two growths some 15 inches high, but clothed to the bottom with healthy leaves, and bearing five flower-spikes, on which were sixty splendid blooms. I understand that this plant has been in Mr. Lane's possession for over twenty years, and goes on yearly improving. This is what I look upon as successful Orchid culture, of a different description to that which occurs where the plants appear to do well for a time and then go off, simply by reason of their treatment being such as gradually undermines and exhausts the naturally strong constitution which the majority of these plants possess. What I plead for in the cultivation of these surpassingly beautiful plants is a rational system of treatment, by giving them much more light, with considerably more air, as also less heat and atmospheric moisture, than the generality of growers subject them to, with, for many, a lower temperature when at rest.

Orchid Baskets.

As the time is now approaching when most Orchid growers re-pot and place in baskets a considerable portion of their stock, a word may not be out of place on the comparative merits of the different pots and baskets in which Orchids are generally grown. All those plants, be they thick or thin-rooted, that in their native habitats grow upon the branches of trees, may be more or less considered as air plants, and there can be no doubt that most of them, were it not for the inconvenience attendant upon watering and inspection, and also the difficulty that would arise in giving sufficient strength to a roof to admit of a large number of plants hanging from it, would succeed better suspended near the glass than they do upon the stages upon which they are usually grown. That such is the case may be inferred from the way in which the majority of plants succeed that are hung near the roof, if their wants are fairly attended to as regards water and other matters; but, from their position, if any plant in a

house gets overlooked, it is almost sure to be one that is hung up. In support of this view, in respect to plants hanging, I may say that one of the best-grown collections of Orchids I ever saw was principally suspended in this way, with the exception of such varieties as are found growing naturally upon the ground; but, independently of this general view, there are some species that absolutely refuse to grow unless suspended; and such as the pendulous *Dendrobiums*, from their natural habit, require to be hung up. Baskets and blocks then become a consideration. Ordinary pots neither look well nor, from their weight, are suitable for this purpose. Many Orchids grow well upon a block of wood or in a basket made of wood, and both look well if the baskets are artistically made. But there is one drawback common to wood for this purpose, in whatever way it is used, viz., the rapidity with which it becomes rotten in the damp moist atmosphere of an Orchid-house. Anyone who will look at the habit of these plants, and notice the tenacity with which their roots cling to whatever they lay hold of, cannot fail to come to the conclusion that, of all plants, they are the least adapted by Nature for being frequently removed in a way that must necessarily involve a wholesale destruction of their roots. To avoid this, rustic earthenware baskets, made to imitate natural wood, have been invented, perforated and fastened together at the corners with wire, just in the way in which baskets are made of Maple or Oak. They are manufactured at Weston-super-Mare in sizes from a few inches up to such as will accommodate a plant of *Aërides* or *Saccolabium*, for both of which, as also for *Phalænopsis*, *Dendrobiums*, &c., they are well adapted. The great advantage in growing Orchids in

Rustic Pottery-ware Orchid Basket.

such baskets is that there never is occasion to disturb the roots, for, if a plant requires fresh material in the shape of peat and Sphagnum, nothing is easier than to remove all the effete soil, then take the syringe, and with tepid water wash the whole quite clean and free from any earthy matter that is getting in a condition unfit for the roots. Drainage in the shape of crocks, or, better (because lighter), wood charcoal, can then, if required, be introduced, filling up amongst the roots with the ordinary potting material; and if the plant requires a larger basket, all that is needed is plunging it, as well as the basket, into a larger one prepared with Sphagnum, peat, and the usual materials for keeping the soil open. That Orchids can, with the great advantage of never receiving a check in potting, be so treated I have found by in this way plunging such as were grown in shallow perforated pots; in larger ones, all that is required is to be careful that at each potting the old worn out soil is completely washed away, as described, with the syringe, which is very easily and quickly done, leaving the plant a short time to dry before placing it in another receptacle.

T. BAINES.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Convenient Flower Pots for Trellises.—It occurred to me the other day, whilst fixing a wire trellis to a pot, that it would be an improvement if some large flower pots were made with four or more pairs of small holes round their edges, viz., from the top of the rim inside to the bottom of the rim outside, so as to admit a small copper wire one-sixteenth of an inch in diameter, and about a quarter of an inch apart. In this way the ring at the bottom of the trellis could be more firmly fixed to the top of the pot. The four or more prongs generally attached to trellises do not hold them sufficiently firm, and the holes which I suggest, being small and neatly made, would be no disfigurement to the pots, which would also be useful for training Geraniums and other plants for purposes of exhibition.—THOS. MOUNTFORD, *Port Hill, Stoke-on-Trent, Staffordshire*.

Cutting-pot Maggots.—I have sent you a few specimens of a destructive maggot which has preyed upon some of my plants for years. It eats the pith out of my Geranium cuttings, which, in consequence, turn sickly, and die. It also attacks Chinese Primulas and some others. We watch carefully, and kill all we can find of them, but cannot get entirely rid of them; I think they breed in leaf-mould and other decaying matter and thus get into the soil. Can you furnish me with any remedy? Those sent, twelve in number, were all taken from a plant of *Primula denticulata*, the roots of which, when turned out of the pot, were found to be eaten asunder.—W. DIVERS, *Wierton House, near Maidstone*. [The maggots sent are the larva of the destructive beetle *Otiorynchus sulcatus*. Handpicking at the roots is the best remedy when they have established themselves in beds or pots; but for cutting-pots we should imagine that care in examining the soil used, and, where necessary, roasting it should keep the pots free from them.—A. M.]

TREES AND SHRUBS.

SOME FLOWERING TREES AND SHRUBS OF NORTH AMERICA.

By HARLAND COULTAS.

Stuartia virginica.—This beautiful genus consists of two species, well-deserving of cultivation as ornamental flowering shrubs. They have large handsome flowers which are white in *Stuartia virginica*, and have the five styles of the pistils united into one; but are cream-coloured, and rather larger, in *Stuartia pentagynia*, the five styles being separate. The last species is perfectly hardy in England, and at Philadelphia, and is found on the eastern slope of the Alleghanies in Virginia.

Gordonia Lasianthus (Loblolly Bay).—A fine tree, indigenous to swamps or moist turfy soils, growing to a height of from 50 to 80 feet, in the low country from Virginia to Florida, and ripening fine capsules as far north as Laurel Hill, Philadelphia. Its flowers are large, showy, white, and sweet-scented. This beautiful flowering shrub deserves to be treated with more care than it has hitherto received in England. The soil should be peat, leaf mould, or sand, and be always kept moist. The other species (*Gordonia pubescens*) has obovate-lanceolate leaves, pubescent beneath, and flowers almost sessile, but large, white, and fragrant. The capsule is globose, brownish, and ripens in October. It is somewhat hardier than the preceding species, but requires the same general treatment.

Magnolia glauca (Sweet Bay), called also Swamp Sassafras, Beaver-wood, and White Bay.—It is called Beaver-wood because those engineers and architects, the beavers, use its wood in the construction of their dams and houses. A shrub from 4 to 20 feet in height, growing in swamps from Massachusetts southward, near the coast. In the Southern States the flowers appear in May, and in the Northern States a month later. The flowers of the *Magnolia* are collected and sold in the New York and Philadelphia markets in the month of June. This elegant shrub or tree stands the climate of Europe well, and ripens its seed in the neighbourhood of Paris.

Magnolia acuminata (Pointed-leaved *Magnolia* or Cucumber tree), so called in allusion to its fruit, which resembles a small Cucumber. The leaves are oval, acuminate, and from 5 to 10 inches in length; the flowers, large, bluish-white, often with a tinge of yellow, are followed by a reddish fruit, which is highly aromatic and fragrant. This *Magnolia*, in the Alleghanies of Pennsylvania, is a splendid mountain tree, rising sometimes to a height of 120 feet, and growing at lower and more sheltered elevations in the forests of the Alleghanies mixed with other trees, from which it is most readily distinguished by its large dark green leaves and handsome flowers.

Magnolia grandiflora (Great Laurel *Magnolia*).—This species has thick evergreen leaves, from 6 to 12 inches in length, deep green, and shining above, and rusty-coloured beneath, with large deliciously fragrant white flowers. It is a native of North and South Carolina and Georgia, and endures the American winters as far north as Philadelphia. A truly noble tree, from 60 to 80 feet in height.

Magnolia Umbrella (Umbrella tree), so called because its leaves are crowded on the summit of the flowering branches in an umbrella-like circle. These leaves taper at both ends, and are from 1 to 1½ foot in length, glabrous, or smooth. Flowers, white, slightly scented. Cone of fruit, rose colour. Pennsylvania, Virginia, and Kentucky, along the Alleghanies. Height of tree, 25 to 35 feet. (*M. tripetala*, Michx.)

Magnolia Fraseri (Ear-leaved Umbrella tree).—This has leaves a foot in length, obovate-oblong, auriculate, or having two rounded appendages at their base, like ears. Flowers, white and fragrant. Tree from 30 to 50 feet high. Virginia, Kentucky, and southward.

Magnolia macrophylla (Great-leaved *Magnolia*).—The foliage of this handsome tree is truly magnificent, the leaves being from 2½ to 3½ feet long. Its flowers measure from 8 to 12 inches in width, white, and fragrant. It is a native of the Southern and some of the Western States, in rich and shaded woods, Florida to Tennessee. A small tree from 20 to 40 feet in height. The leaves and flowers of this tree, which extends itself into the zone of sub-tropical evergreens, and requires, for its growth, a mild and genial climate, give to its physiognomy a peculiarly exotic aspect.

Liriodendron tulipifera (Tulip tree).—Also sometimes called the White Poplar. This noble tree has been justly regarded by all who have seen it as the pride of the American forest. A special feature is given to its foliage, by its broad, lobed, and curiously truncated smooth leaf, the top of which appears as if transversely cut off. In America its stem is as tall and straight as the mast of a ship, growing without a limb to nearly 100 feet in height. Its shape, peculiar to trees crowded together in deep forests, and which has often been

described as the result of the action of top light, is perhaps most strikingly seen in the Tulip tree, which is easily known, even from a distance, by the straightness of its stem.

Celastrus scandens (Shrubby Bitter-sweet).—This is a climbing shrub, with a twining woody stem, allied to the European Spindle tree (*Euonymus europæus*). It is noticed because it is an elegant climber, and highly ornamental when trained upon trellis work or around the supports of a piazza, especially in autumn, when its open orange-coloured three-celled capsules display the scarlet covering of the seeds. The *Euonymus atro-purpureus* (Burning Bush) belongs to the same family. It is an upright shrub with deeply-lobed capsules of a deep red colour, which present a brilliant appearance after the leaves have fallen. The fruit is often introduced into autumnal bouquets, to which it makes a pleasing addition.

Cladrastis tinctoria (Yellow Wood).—A small but handsome tree, with yellow wood, smooth bark, pinnate leaves, and large white flowers, in terminal, drooping racemes. Rich hillsides, eastern Kentucky and southward along the western base of the Alleghanies.

Cercis canadensis (Red-bud Judas Tree).—Trees with rounded heart-shaped simple leaves, and red purple flowers appearing before the leaves, early in spring, in such abundance, that not only the branchlets and branches, but even the trunk itself, is clothed and empurpled with their clusters. This tree, therefore, deserves to be better known than it is, and to have a place among our cultivated ornamental trees.

Wistaria frutescens (Glycine, Carolina Kidney Bean, named in honour of Professor Caspar Wistar, of the University of Pennsylvania, Philadelphia).—A beautiful wall plant, a native of the alluvial soils of the Southern States. The lilac-coloured flowers are in large and handsome racemes, but are inferior in size and beauty to the Chinese species (*Wistaria chinensis*), which is much more frequently cultivated. The Chinese plant is not, however, so fragrant as the American.

Prunus americana (American Yellow Plum).—This tree is extensively diffused throughout the States from Canada to Texas. The stem is from 8 to 15 feet high, much branched; the flowers are white, and the fruit, mostly orange-coloured with a rich, succulent, yellow pulp, and a thick tough skin. In a wild state, the flowers are apt to be abortive, and the fruit is small and rather sour, but, by long culture, the drupes, when fully matured, become as large as a common Apricot, and have a pleasant flavour, but are not adapted to culinary purposes.

Prunus maritima (Beach Plum, Sand Plum).—This species is found along the coast from Massachusetts to Virginia, and often extends inland for more than 20 miles. When growing at a distance from the sea, its leaves are smoother and thinner and the fruit smaller, forms which have been considered, by some botanists, distinct varieties, and even species. It is a low straggling shrub, from 2 to 5 feet high, growing in little thickets, and, in exposed situations, it is nearly prostrate. The fruit varies in quality, but, when fully ripe, is usually of a very agreeable flavour, and is sometimes sold in the American markets. The Beach Plum is much used for preserving along the New England coast.

Prunus cerasus (Red or Sour Cherry, Morello Cherry).—The Sour Cherry is the most common, and, for culinary purposes, the most valuable of the native American Cherries. The Morello Cherry is a remarkably fine variety, with a rich purple juice. The stem of this tree is from 10 to 20 feet high, and supports a round bushy top.

Prunus serotina (Wild Black Cherry).—This tree attains its greatest perfection on the fertile banks of the Ohio, and other rivers of the West, where it forms a fine forest tree from 60 to 80 feet in height, the stem dividing into a number of branches and forming a widely spreading umbrageous mass. On the lowlands of the States, however, it only reaches to about half the height of the mountain form, which is placed in very different circumstances. It grows in the depths of the gaps and ravines of the Alleghany Range, closely surrounded by other tall trees, and as its lower limbs become shaded and atrophied, they dry up and drop off, the trunk or stem thus struggles up into a naked symmetrical shaft, the terminal branches forming a leafy summit or canopy, which continues to rise higher and higher as the mass of the forest rises in the air. A stem, often 5 feet in diameter, without a branch for 90 feet, and as straight as a gun barrel, is a common form of the plant in these woods, the height of the entire tree averaging about 125 feet. This is the Cherry timber so much valued for cabinet work. Wild Cherry bark ranks very high among the articles of the materia medica. The ripe fruit is a favourite food of birds, and is much used in the preparation of Cherry brandy.

Prunus caroliniana (Evergreen Cherry).—Tree, 30 to 50 feet high. Leaves, oblong-lanceolate, shining, evergreen. Flowers, small, white, and racemose. Banks of rivers, Florida to North Carolina. This tree is noticed on account of the poisonous nature of its leaves.

It is closely related to the European Cherry-leaved Laurel (*Prunus laurocerasus*), so common in English gardens, the leaves of which, when crushed, give forth the vapour of prussic acid, a deadly poison, and in sufficient quantities to destroy insects when confined with them. With this object in view, entomologists, when out collecting, carry crushed Laurel leaves with them in a bottle.

Pyrus coronaria (American Crab-Apple).—A tree from 15 to 20 feet high, having ovate and sometimes rather heart-shaped leaves, with large, rose-coloured, fragrant blossoms, and small sweet-scented greenish-yellow, extremely acid, fruit. This native Apple is in demand among American housewives for preserving.

Pyrus americana (American Mountain Ash).—This tree is prized in cultivation for its handsome autumnal clusters of bright red berries, which remain attached to the branches, after the leaves have fallen, even through the winter. Grows in the mountains of Pennsylvania and Virginia. It is closely allied to the European Mountain Ash (*Pyrus aucuparia*), which it greatly resembles.

Hamamelis virginica (Witch Hazel).—This shrub is remarkable for the singular fact that it does not bloom until its leaves begin to fall; hence late in autumn, the four long, narrow, linear, yellow petals of its flowers may be seen amongst its dying, fallen, obovate leaves, in clusters, where they remain upon its flexuose straggling branches for some time after they have lost their foliage. The twigs of the *Hamamelis* were formerly used as divining rods to discover water and metals under ground, by certain professional adepts in the occult art. The species are found in China and Central Asia, besides Northern America. This weird shrub, blooming so late in the fall, in the midst of the desolation consequent upon the decay of so much that is beautiful, is certainly worthy of cultivation, especially by the curious in such matters.

Chionanthus virginica (Fringe tree).—A beautiful tree or shrub, very ornamental in cultivation, belonging to the Olive family (*Oleaceæ*), having snow-white flowers, with long, linear petals, in loose, gracefully drooping panicles, from lateral buds. The petals of the flowers are 1 inch long, narrowly linear and acute, varying from four to six in number; grows in light soil, along river banks from Florida to Southern Pennsylvania.

Halesia tetraptera (Snowdrop or Silver-bell tree).—A shrub or small tree, growing in the Southern States, and also in the upper part of Virginia and Ohio, on river banks. The leaves are oblong, finely serrate, and smooth, and the flowers, which appear with the leaves in March and April, and which are very like the English Snow-drop, hang in beautiful snow-white clusters or short, axillary, drooping racemes from the branches, giving the tree in spring a very attractive appearance, and rendering its popular name at that time peculiarly appropriate. The other species (*Halesia diptera*) grows in the woods in rich leaf mould, away from rivers and streams of water. Both species well deserve extensive cultivation as ornamental shrubs.

Cornus florida (Dogwood).—This is a valuable as well as ornamental little tree, worthy of a place in every park and garden. Its stem and branches are altogether from 20 to 30 feet high. The flowers are greenish, in a head or close cluster, which is surrounded by a large and showy four-leaved involucre of bracts, white, inversely heart-shaped, and notched at their apex. This tree is quite common in the American woods, making a great display in spring when in flower, and an equally fine show in the fall when in fruit, as its branches are then covered with the clusters of bright red oval drupes which succeed the flowers, and its leaves are tinted beautifully with different shades of yellow, pink, and purple.

Catalpa bignonioides (*Catalpa* Indian Bean).—This is a common ornamental shade tree, cultivated in Philadelphia and other northern cities. It has large cordate, acuminate, entire leaves, and showy flowers, which are white, slightly tinged with violet and dotted with purple and yellow in the throat, appearing in July. Pods, hanging till the next spring, often 1 foot long. Indigenous in the South-western States.

ROYAL HORTICULTURAL SOCIETY.

THE annual meeting of the Fellows of the Royal Horticultural Society took place on the 9th instant, under the presidency of Viscount Bury. The Report which was read stated that the finances of the Society had occupied the serious attention of the Council, as it had been found impossible to make any reduction in the debt alluded to last year. Since the present Council had been in office, they had been called upon to pay debts previously ignored in the Society's published accounts. Sir T. Drake advanced, prior to 1860, £1,000 to the Society, without interest, and this debt had been compromised for £600. The ordinary revenue of the Society could not support its expenditure, although reductions had been made which would prevent

any increase of liability in 1875. The Council would have to pay rent to the Royal Commissioners in 1876, and the Fellows would have to make up their minds definitely either to risk the loss of the Gardens at South Kensington or to subscribe more largely. If the lease of the Gardens was voided, the debenture-holders would lose the sum of £50,000 advanced on the property. The balance-sheet showed that the income of 1874 amounted to £7,781 11s. from annual subscriptions and admission fees. Exhibitions, sale of garden produce, and miscellaneous receipts made the total income £11,673 3s. 2d. The expenditure showed £1,809 0s. 5d. for establishment expenses; special expenses in relation to horticulture, £701 4s. 5d.; Chiswick Garden expenses, £2,091 15s. 4d.; Kensington Garden expenses, £2,401 13s. 3d., and interest on debentures, £1,962 6s. 7d. The Royal Commissioners, it was stated, were willing to meet the Council openly and fairly. The Society did not meet its expenditure, and therefore it was necessary that some plan should be devised to improve the income. Sir Henry Thring said he was authorised by the Commissioners to state that they were not in the slightest degree hostile to the Society. It was their wish that the land at South Kensington should be kept as a garden. He did not approve the language of the report and hoped it would be referred back to the council, in order that some arrangement might be come to between the Commissioners and the Council. Mr. Shirley Hibberd moved that the report be referred back to the council for reconsideration. Dr. Denny seconded the motion, and said if the Society did not pay the rent of the Gardens next year the lease was liable to be voided. Mr. Edgar Bowring, C.B. (one of the Royal Commissioners), said from the moment the Commissioners were advised that the present council of the Society was a legal one they would be ready to enter into negotiation with the view of improving the Society's finances. After a long discussion the motion was withdrawn. The chairman said, considering the statements made on behalf of the Royal Commissioners, the council would consent to an adjournment of the meeting, with the view of considering the terms of an amicable agreement between the two parties.

ANOTHER CHARTOMETER.

THE accompanying little map measurer to my knowledge has been in use for nearly twenty years. The little milled wheel runs along a very fine screw from one side to the other. To use it, you must run the wheel close up to one of the shoulders, and then follow the road on the map. Should the distance be such as to allow of the wheel arriving at the next shoulder, you must recollect the exact point at which it stopped, and then retrace it along the scale which is attached to all maps. See how often the scale is traversed, and then proceed afresh. The thread on the screw being very fine, you will find that a considerable number of miles will be measured before the wheel arrives at the end of the screw. These little instruments are necessarily accurate, because the wheel must run back exactly as far on the scale as it went on the map. The price is only 3s. 6d., I believe; and they may be carried in a portemonnaie. I have drawn it the full size. I have been assuming that the distance wished to be known requires the wheel to run to the full extent and more; but it may probably happen that a third, a half, or any other intermediate measurement, is sufficient. In either or any case, you simply reverse it on the scale, and as soon as the wheel reaches the shoulder from which it started, you at once know the result.—"Field."

Ingratitude.—It is usually supposed that crowned heads and people of that sort invariably take all they can get in the way of earthly goods. A knowledge of this fact lately moved a person in Fulton, New York, to prepare a half-barrel of the soft and enticing compound called Apple butter, and to dispatch the same, as per address, to "Her Majesty Queen Victoria, Buckingham Palace, England." Such graceful and beautiful little attentions as this are what cement the bonds of humanity and shed a soft light of *tol-de-rol* over the dreary pathway of existence. It is to be hoped that this kindly gentleman will not have an experience like that of the Michigan farmer, who shipped a barrel of flour to the same crowned head not long ago, and while promising all his neighbours to show them the autograph letter of thanks, was slightly amazed to learn that his barrel had been sold at auction with some other unclaimed and less legal freight.—"New York Tribune."

THE HOUSEHOLD.

Cooking Rhubarb.—Rhubarb is best cut in lengths, boiled in water and sugar, and served with boiled Rice round the dish; or it may be treated like "Gooseberry fool." A little good cream gives it a delicate taste, which it never has in a pudding or tart. The following are excellent recipes for making Rhubarb jam and marmalade:—Cut the Rhubarb as if for tarts, and to every quart give 1 lb. of good moist sugar; put the sugar over the Rhubarb, and leave it twenty-four hours to draw out the juice. The sugar sinks, but does not dissolve. Boil the sugar and juice together for twenty minutes; after it begins to boil just at the edge of the pan add the Rhubarb, and boil slowly twenty minutes longer. There is no need to stir the syrup or preserve if slowly boiled. The Rhubarb and sugar do not require a warm place to draw out the juice. By this method the pieces of Rhubarb remain separate from each other when the preserve is done. It keeps good a year if kept in jars well dried and in a dry place. For the marmalade procure six Oranges, peel them, and take away the white rind and pips, then slice the pulp into a stewpan along with the peel, cut very small; add thereto one quart of Rhubarb, cut finely, and from 1 lb. to 1½ lbs. of sugar. Boil the whole down in the usual way, as for other preserves. Made in this manner, it is nearly equal to Scotch marmalade.

Tapioca (Manihot utilisima).—This useful starch is the produce of a plant that is cultivated extensively in the Malay Peninsula, where its culture is almost entirely in the hands of the Chinese. Tubers, which weigh on an average from 10 to 25 pounds, are first scraped and then carefully washed; after which they are reduced to a pulp by being passed between rollers. This pulp is carefully washed and shaken up with abundance of water, until the fecula separates and passes through a fine sieve into a tub placed beneath. The flour so obtained is repeatedly washed, and then placed on mats and bleached by exposure to the sun and air. It is finally converted into the pearl tapioca of commerce by being placed in a cradle-shaped frame covered with canvas; it is slightly moistened and subjected to a rotary motion, by which means it is granulated. It is next dried in the sun, and finally over the fire in an iron pan greased with vegetable tallow, when it is ready for the market.

French Pot au Feu.—Take a piece of fresh silver-side of beef weighing 6 lbs., and about half a pound of bones; tie up the meat neatly with string, and put both into a six-quart saucepan; fill it up with sufficient water to come well over the meat and bones, and set it on the fire; remove carefully with a skimmer the scum that will rise as the water gets warm, but do not allow it to boil. Add at intervals during the process about a pint of cold water in small quantities; this will have the effect of checking the ebullition, and will help the scum to rise. When the scum is all removed, put in about 1 oz. of salt, a small handful of whole Pepper and Allspice, one Onion stuck with a dozen Cloves, one Onion toasted almost black before the fire or on the hob, one Leek, and three Carrots of average size cut in 2-inch lengths, two Turnips of average size, each cut in four; and, tied together into a small faggot, two Bay leaves, two or three sprigs each of Thyme and Marjoram, a clove of Garlic, and a small handful of Parsley. The above vegetables should not be put in all at once, but gradually, so as not to check the gentle simmering of the *pot au feu*, which should be now skimmed for the last time, and placed by the side of the fire to simmer gently for at least four hours. According to the season, all or some of the following vegetables may be added; a head of Celery cut in 2-inch lengths, a couple of Tomatoes, a couple of Parsnips, a handful of Chervil. At the time of serving strain the broth and skim off all the fat, add the least bit of sugar (not burnt sugar), and more salt if necessary; make the broth boiling hot, and pour it into the soup-tureen over small slices of toasted bread, adding, according to taste, a portion of the vegetables cut in thin slices. To serve the meat, having removed the string, garnish it with some of the vegetables, or with mashed Potatoes, Spinach, &c.

THE LATE MR. W. P. AYRES.—The widow of this well-known horticulturist having been left wholly unprovided for, some of his friends have determined to raise a subscription for her benefit. I am confident that many who remember the services rendered to horticulture by Mr. Ayres, both personally and by his pen, will be ready to lend their assistance towards the accomplishment of so charitable an object, and will be only too pleased at having an opportunity of doing so. I would rather not receive subscriptions myself, but I have no doubt that the editors of our horticultural papers would, if requested, gladly do so, and I am ready to give what I can afford for the purpose in question.—JNO. WILLS, Onslow Crescent, Onslow Square, Brompton.

MR. JOHN BELL died on the 3rd inst. at his residence, Heath Cottage, Thorpe Hamlet, Norwich, aged seventy-one. For thirty-nine years he was a nurseryman and seedsman in that city.

NOTES AND QUESTIONS.

Double White Primulas.—I should feel obliged by some of your readers telling me how to grow these lovely winter flowers in perfection.—PRIMULA.

Sulham Prize Celery.—I have this season grown a couple of rows of this truly exquisite Celery, and I find it to be an excellent keeper, and to possess the true nutty flavour which Celery ought to have. It is not large, but it is compact, tender, and in all respects an admirable variety.—R. GILBERT.

Fertilising Aucubas.—In addition to what was stated in reference to this subject in your last year's volume, allow me to say that two years ago I planted from a pot a small male Aucuba, and last year eight bushes, twenty or thirty yards off, some of them 10 feet in diameter, of the female sort were so covered with berries that half a bushel might readily have been picked from them. Last spring the frost appeared to have killed the male flowers, but all the female plants have, nevertheless, borne a great many berries.—W. BURN, *Chilts Hill, Wood Green.*

The Best Scotch Firs.—Permit me to say, in answer to your North-country correspondent's objections to my remarks in regard to the natural woods of Fir and Pine in Norway, that he furnishes an additional illustration of their correctness. I said that finer examples of Pine and Fir could be found in almost any English estate than their native (*i.e.*, Norwegian) woods afford. By English I meant, of course, the United Kingdom. Your correspondent does not seem to know that *Pinus sylvestris* is as much a native of Norway as of Scotland, and might as justly be called the Norway Pine as the Scotch.—W. INGRAM.

Propagating Roses.—After my Roses in pots have done flowering I see them round some heaps of potting mould and layer all the shoots on the sides of the heaps, giving them at the same time a sharp bend so as to cause a slight wound. By the end of October they will be found to be well rooted, when the strongest of them are potted and plunged in a slight hotbed, the tops being, however, exposed in order to encourage root action; the small ones are planted out in a nursery bed until they are wanted for pot culture or for planting in beds. This method of increasing Roses may not be new, but it is a good way of utilising wood which would otherwise be cut off and thrown away.—WILLIAM NEANE, *The Gardens, Hampton Court House.*

Propagating Mistletoe.—Save the berries, get them well dried, and insert them in the bark of the selected tree after the fashion of budding Roses, the sap in the tree being up. Mistletoe, as a rule, grows best on decayed Apple trees; and it seems common in the south of Gloucestershire for it to abound in trees which have passed their best, growing on the decayed parts most freely—the birds no doubt carrying the berries. I have myself this Christmas seen a very small sprig sold for 2s. 6d. in the north of Gloucestershire; here in the south the owners of orchards and plantations would freely give it to a man who would remove it carefully from their trees. It is very injurious to every kind of timber, and quite a poison to cattle. It would seem, however, that during the late frost the birds have freely partaken of the berries, so as to leave but very few for purposes of propagation.—"Field."

Proposed Potato Exhibition.—An effort is being made to establish the nucleus of a permanent Potato exhibition in or near London. That well-known grower, Mr. Peter McKinlay, of Beckenham, has taken the initiative by issuing, to all interested, a circular inviting co-operation and support in the matter; and so great is the interest now felt in the cultivation of the Potato amongst all classes of persons, that there can be little doubt the response will be general and hearty. It must not be forgotten that whilst the Potato receives encouragement at almost every Provincial Show, large or small, yet that now, when the South Kensington November exhibition has been abolished, not a penny is offered for its encouragement at any Metropolitan Society's Exhibition. Of course the prizes so liberally offered by some of our eminent seed firms are not overlooked, but these are wholly independent of societies. Should Mr. McKinlay be satisfied with the way in which his circular is met, a thoroughly representative committee will be at once formed and a liberal schedule of prizes issued. It is hoped that the show may be held at the Crystal Palace; but in any case it is earnestly to be desired that a really national exhibition of this valuable tuber may be the result.—A. DEAN.

Nepenthes at Drumlanrig.—At p. 360, Vol. VI., of *THE GARDEN* you refer to some "well grown" pitchers from these plants which you received through Messrs. Veitch. I saw the plants in question late last autumn; the principal ones occupy a hot moist end of a large exotic plant stove. They are all growing in remarkably small square baskets made of unpeeled Hazel sticks, and the roots derive their support from pure living Sphagnum. The Sphagnum is in a thriving state; it was about 4 inches in length, and so strong that each spray would have stood upright itself. It grew out of every nook and corner of the baskets, and hung over their sides in verdant masses. This is evidently the company the *Nepenthes* delights to be in. The plants are good examples of high culture, and they show how perfectly they may be grown in a common plant stove. The following are the chief varieties grown at Drumlanrig:—*N. Rafflesiana*, *N. gracilis* major, *N. Sedeni*, *N. Hookeri*, *N. phyllamphora*, *N. Dominii*, *N. hybrida* maculata, *N. rubra*, and *N. distillatoria*. The latter is trained up and goes the full length of a 22 feet rafter. Dozens of pitchers that would hold a pint hang down in grand profusion, and indicate how well adapted this variety (which is sometimes grown under the name of *N. Khasyana*) is for climbing. The other varieties mentioned were suspended from supports put up for the purpose.—J. MUIR.

Draining Gravel Walks.—I am desirous of draining my gravel walks upon the plan recommended in the *GARDEN* for January 30, p. 91; what diameter of drain pipes should I use? and how far apart should the "eyes" be? I conclude these eyes are a small sort of cesspool; can you give a hint as to the cheap construction of such "eyes." The walk is 6 feet wide, and is about 100 yards in length.—S. [The size of piping required to drain a hundred yards of walk supposed to be continuous—consequently all the surface water from the whole length would have to be carried through the pipes to the main drain of the garden—should be 4 inches in diameter to ensure the water being carried off as quickly as it falls in heavy thunder showers; or even pipes 6 inches in diameter might be necessary if any considerable portion of lawn, or other ground, slopes towards the walk, which would receive the surface water from such surroundings. On a walk that is nearly level the eyes should be placed on each side, at intervals of 25 yards or so; but if the descent is rapid, giving the water considerable force, they should not be above half that distance apart. The cheapest way of making them is with common bricks, built up so as to form 4½ inch square openings or eyes, on the top of which place the ordinary iron grids that are about a couple of inches larger than the eyes, which consequently give them a bearing. They should, if possible, be let into a square wooden frame lying on the top of the bricks, or still better one of stone and similar in shape; if merely laid upon the bricks which form the eye they are liable to get displaced every time the roller passes over them.—T. BAINES.]

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

DECIDUOUS TREES IN WINTER.*

By JAMES M'NAB, Royal Botanic Gardens, Edinburgh.

WE often meet with people who are utterly incapable of discriminating between the various kinds of forest trees when bare of leaves, although they may be in the habit of walking daily through forest scenery. A very general belief, in fact, seems to prevail that it is impossible to distinguish trees when stripped of their foliage. This, however, is far from being the case, as I shall presently show. The pleasures of a country walk in winter may be greatly enhanced by a recognition of our summer friends amidst the bare trunks and leafless branches that surround us, and it is always an enjoyment, when visiting any country district during the winter months, to be able to tell every tree as it comes into view. To the amateur landscape painter, the winter study of trees is highly essential, although I am afraid it is rarely entered upon before attempting to delineate them on canvas, and this want of observation, or rather the want of the technical knowledge that observation alone can give, frequently leads to their being incorrectly represented. It is quite possible to paint trees in a winter scene (when they are free from snow) so as to render them as easily recognisable by an experienced observer, as they are, or ought to be, when the more noticeable characteristics of their foliage are depicted. Even in the case of the Birch, it is not its graceful outline and the general disposition of its spray, composed of small upright, diverging, or pendent twigs, of a uniform thickness, that usually determine its identity, but the peculiar white bark, which is common to the species at all seasons. The same general remarks are also applicable to many summer landscape effects. While looking over the exhibitions of modern pictures, how seldom do we find representations of trees which enable us at a glance, and with absolute certainty, to name the original. The Scotch Fir, Lombardy Poplar, and Birch can generally be recognised, although the fine delicate foliage of the latter is not at all times discernible; and even with the Lombardy Poplar, characteristic as it is, the diameter of its fastigate branches is rarely seen in proportion to its height. The massive round head of the Sycamore or Plane tree, when truthfully portrayed, is easily detected; but even this tree is often represented as sectional, light being often too freely seen through the branches and leaves, which ought not to be the case with any ordinarily well-developed specimen. There is something peculiar in the general outline of almost every kind of forest tree, both in their winter aspect and summer garb, which amateur artists ought particularly to study. The general disposition of the branches, and arrangement of the spray, as well as its openness or density, is always well marked in the different species. It would be easy, at this season of the year, to get correct photographs of good typical specimens of forest trees, to be kept in view while painting any particular tree in a winter scene, so that the arrangement of the chief, as well as the secondary and terminal branches of each kind, should be properly represented as to their density or openness, as well as the relative distance of that density from the points of the branches of each species. The same remarks are also applicable to the summer condition of many trees, photographs being kept for the same purpose, not that the trees should be painted from the photographic representations, but, where we find something definite in the outline, as well as the general thickness, tapering, and divergence of the branches and spray of the different species of forest trees, it is essential that such characters should be kept in view while delineating any particular species. Another fault, and one which is very often observed in pictures, is the relative heights of many of the kinds represented when compared with the diameter of their stem and head. This is the more observable when they stand near objects such as cattle, well-known herbaceous vegetation, &c., with the size of which we are

familiar. Many forest trees are easily recognisable by the texture of their bark, which may be smooth, rough, corrugated, or in flakes. There is no difficulty in distinguishing the Beech, Elm, Lime, Birch, Chestnut, and Scotch Fir, that is, if all the trees are matured; but the foliage does not, in some paintings, always correspond with the bark. Not many years ago a picture was exhibited representing the corrugated bark on the stems of the old Sweet Chestnuts at Fontainebleau. Some of the points of the branches exhibited foliage; but, instead of the leaves being those which belong to the common Chestnut, all were those of the Horse Chestnut, a different tree, with a totally different arrangement of leaf. I shall now endeavour to give a few descriptive remarks on the general arrangement of the terminal branches and spray of some of the well-known forest and ornamental trees usually introduced into pictures; these remarks apply more particularly to their appearance during the early winter months. As the season advances they become more dense, owing to the gradual swelling of the young buds. The practised eye, however, is always enabled, from the disposition of the spray, to recognise them in their different stages. The Ash tree has frequently an irregular outline of head, generally with long undulating branches, particularly on trees standing free. The twigs are somewhat dichotomous, thickened at their points, and project considerably beyond the secondary or side spray. The spray has a loose appearance, and shows a uniform openness all over the tree. The Beech tree has generally a well-developed and regular outline, the main branches tapering gradually from the stem to the points. The points, for the most part, proceed at right angles from the branches, and have an undulating appearance. The side spray is short, and generally turns upwards. The extremities of the branches, for about 3 or 4 feet all over the tree, show a uniform lightness. The bark of the tree is very smooth, and generally of a grey or leaden colour. The Birch, when standing free, has often a regular and very graceful outline. The points are principally composed of small twigs of a uniform thickness, either upright or weeping, generally showing a somewhat netted appearance. The surface of the stem is well known by its white-coloured bark. The Horse Chestnut generally shows a regular outline, composed of numerous sturdy branches, the lower ones drooping. The branchlets are by no means crowded; a foot or two of each of the points is observed to turn upwards. They are strong, of a uniform thickness, and somewhat open and regular all over the tree. The bark is of a greenish-grey colour, and partially roughened. The common Chestnut, when standing free, has a regular outline of head, the branches strong, and more or less pendent. The extremities are numerous, and all thickened towards the points. Although the main branches are pendulous, the points are generally bent upwards, and show a uniform thickness all over the tree. When old, the bark assumes a somewhat corrugated and rough appearance. The outline of the English Elm is frequently very irregular, most of the branches projecting upwards, some considerably beyond the rest. The terminal spray is more or less upright, very twiggy, and with a confused appearance, the darkest part being 10 or 12 inches below the points of the twigs. The bark is generally of a dark and rough nature. The outline of the Scotch or Wych Elm, although somewhat regular, has the upper branches, as well as the spray, in long forked lengths, more or less diverging. On this account it frequently receives the name of the Y tree, from the branches resembling that letter. About 2 feet from the points of the branches is generally the most open part, and this is the case all over the tree. The outline of the Lime tree is regular and the head somewhat rounded. The spray is thickest about 1 foot within the general outline. The terminal branches and spray are upright, and the lower side branches more or less drooping, but all have a tendency to turn up at the points. The bark is somewhat smooth, and generally very green, being covered with a small fungus known as *Chlorococcum*. The common Oak has more or less an irregular outline. The main branches, as well as the secondary and terminal ones, generally diverge very much; the points of all protrude from 2 to 5 inches beyond the numerous semi-whorles of small side spray, which generally incline upwards. The bark is rough, and of a dark colour. The Turkey Oak is generally very tall, with an

* Read before the Botanical Society of Edinburgh, 11th February, 1875.

irregular outline; the main, as well as the top branches, more or less erect, and generally in long straight shoots, their sides being covered with spray a few inches long. The general density of the spray is by no means great, but very uniform all over, except at the points, which are long and stand free. The black Poplar has rather an irregular outline, composed of large massive limbs, the smaller branches ramifying much towards the points, giving the outline of an old tree a somewhat netted appearance, but always thickest about two feet within the general outline. The Robinia has a very irregular shape; the main branches generally assume a tortuose or zig-zag appearance, which is observable even at the extreme points. The branchlets and spray are short; a uniform lightness is observed all over the tree. The Sycamore, or Scotch Plane, has generally a regular outline, composed of large massive branches, each portion being more or less rounded, and terminated with numerous tessellated points, mostly turned upwards and slightly thickened, generally darkest round the outline of the tree. The bark is frequently green with chlorococum, and somewhat roughened. The outline of the Walnut is often very irregular, and branches much. Many of the branches, as well as the tops are somewhat dichotomous. The terminal, as well as the side spray is strong, and has a uniform openness throughout. The Willow, when seen large, is generally composed of low bending stems, their points assuming a slightly elevated habit, which as they ascend, the upper portions become more or less erect; a uniform openness is observed all over the tree.

NOTES OF THE WEEK.

— MR. J. TYERMAN has sent us, during the past week, a box of Narcissi, which are now flowering freely in the open air at Tregoney, Cornwall. The collection includes *N. Pseudo-Narcissus*, *N. Telemonius*, *N. minor*, *N. minimus*, *N. Tazetta* (a fine large form with golden-yellow cups), and the true *N. intermedius*, with stellate golden flowers, semi-cylindrical deep green foliage, and smooth cylindrical scapes.

— WE have received direct from America a most excellent sample of canned Tomatoes of the "Bordentown" brand. These are grown and preserved on the Bordentown Fruit Farm, New Jersey, and are far superior to any we can obtain in London, the flavour being equal to fresh fruit when fully ripe, and far superior to fruit grown in pots indoors during the winter season.

— FOR the article (see page 157) on the Vine pest now devastating the Vineyards of France, we are indebted to Professor Riley, of St. Louis, the State entomologist for Missouri, who has paid much attention to this minute, but terrible, pest. The article cannot fail to be useful for reference to all who have to combat the attacks of the Phylloxera.

— AT the last meeting of the Royal Horticultural Society (Wednesday, 17th inst.) a first-class certificate was awarded to the Rev. George Kemp for a dish of *Beurré de Jonghe* Pears, in very fine condition for the season of the year. The delicious flavour and fine keeping qualities of this fine Pear ought to make it a favourite with amateurs and fruit-growers for market.

— *SAXIFRAGA BURSERIANA* and *S. pyrenaica rubra* are now in flower on the rock-work in the York Nurseries. *S. Burseriana* has pure white, almost circular, flowers, borne on slender pubescent scarlet stems, from 1 to 2 inches high. This Saxifrage is a beautiful object for many weeks even before the flowers expand, the buds, when they first appear, being almost scarlet, which slowly changes to a dull red when the flowers begin to expand. The stems remain scarlet throughout the flowering season. *S. pyrenaica rubra* belongs to the opposite-leaved section, but has upright rosettes and large deep crimson flowers, which slightly change with age to a lighter crimson. It is a very fine variety.

— THE laying out of Cannonhill Park, Birmingham, is being pushed forward with vigour. Between sixty and seventy workmen are at present engaged in operations which, when completed, will add both to its beauty and utility as a recreation ground. A new lake, diversified by islands and bridges, is to be formed, which will cover an area of between 4 and 5 acres, and on its southern shore, extending its full length, it is proposed to raise an artificial mound, from which the whole of the cricket ground and other important features of the park will be overlooked. In addition to the excavations going on at the lake, the turf on and around the croquet-lawn is being relaid. Mounds will here and there be raised, trees planted, and a large extent of new shrubbery formed. These alterations, from designs

furnished by Mr. Marnock, are being carried out, under a contract, by Mr. Meston, at the expense of Miss Ryland, the donor of the park. The whole of the works are expected to be finished about midsummer.

— FOR the sake of our illustrations—both coloured plates and engravings, readers who obtain THE GARDEN through newsagents, booksellers, or at the railway bookstalls, should request that the paper be delivered in an unfolded state.

— IT has been determined to hold the next meeting of the American Pomological Society in Chicago, and it is expected that the meeting there will be of more than usual importance.

— THE Metropolitan Floral Society have been enabled to make arrangements (through the liberality of the Directors of the Alexandra Palace Company) for holding a great autumn exhibition of flowers in Alexandra Park on August 24th and 25th.

— THE collection of dried plants from the banks of Lake Tanganyika, made and sent home by Lieutenant Cameron, is now in the hands of Dr. Hooker. Unfortunately, the specimens were injured on the way down to the coast; but they have been sufficiently preserved to be of use.

— AMONGST the most valuable of imported fruits at this season is the Pomello, which is now abundant in the London markets. It belongs to the Orange tribe, and is, in fact, a smaller kind of Shaddock of peculiarly delicate flavour. It is sometimes called Forbidden Fruit.

— A DINNER-TABLE at the City of London Club, the other evening, seemed to us to be unusually well decorated with flowers, which were combined with gold and silver ornaments with much taste and effect. The brilliancy of the flowers was agreeably toned down with foliage, furnished by such plants as *Dracænas* and Maiden-hair Ferns.

— THE Leeds Professional Gardeners' Benefit Society seems to be in a flourishing condition, judging from its annual report. The income of the society for the past year amounted to £144 18s. 2½d., and the expenditure during the same period was £116 9s. 6½d., leaving a balance of £28 8s. 8d., which brings the funds of the society up to £433 12s. 0½d.

— MESSRS. STUART & SONS, of Dundee, state that rates for railway transit of nursery goods have largely increased since the 1st of January last. Last autumn's rate to London from Dundee for trees was 51s. 8d.; now it is 70s. They, therefore, waited personally upon the goods manager at Dundee, who promised to represent the matter at head-quarters, so that the old rates, which were high enough, may be adopted; and they are of opinion that, if all interested would take the trouble of promptly urging their several goods managers to interest themselves on the subject, the result might be important to the nursery trade.

— IT is only a very short time ago since it was supposed that the origin of the true medicinal Rhubarb of commerce had been finally settled, and was the product of *Rheum officinale*, recently figured in the "Botanical Magazine," and admitted in Flückiger and Hanbury's "Pharmacographia;" and already this comfortable arrangement has been disturbed. In a recent number of Regel's "Gartenflora" there is a figure of *Rheum palmatum* var. *tanguticum*, which is described as the "most genuine amongst genuine" Rhubarbs, and as the sort imported into Siberia by way of Kiachta. It was raised from seed collected by Mr. Przewalsky in south-west China on the high plateau bordering on the high lands of Thibet.

— WE have received from the New Jersey Cranberry Growers' Association some bottles of most excellent Cranberry jam which has an advantage over the majority of English made jams, inasmuch as it is a happy mean between the extremes of sweetness and sourness. With our transatlantic cousins this jam has always been a favourite, and it is eaten under a variety of circumstances, some of which are similar to our own use of Red Currant jelly. The culture of the Cranberry is becoming a very important industry in various states in America. We are slow to adopt novelties of this kind, but in days when preserved American Peaches and Tomatoes are seen in our shops, these excellent Cranberry products cannot long fail to find a market here.

— AT the meeting of the Royal Horticultural Society held on Wednesday last, Messrs. Veitch received a first-class certificate for *Abutilon Darwinii*, a free-flowering species, with fresh green trilobate foliage and bright orange-scarlet axillary flowers. It is likely to be very useful as a winter-blooming stove or warm greenhouse plant. A second-class certificate was awarded to *Odontoglossum Warszewiczii*, a native of Costa Rica, exhibited by Messrs. Veitch for the first time. Its habit is similar to that of *O. vexillarium*, and the flowers, in size and colour, remind one of those of *O. Phalænopsis*. Messrs. Caldwell, of Knutsford, furnished a well-grown plant of *Azalea amœna* Caldwellii, a variety with much larger flowers than those of the type, and evidently a plant which will be valuable for purposes of early decoration.

THE GARDEN IN THE HOUSE.

BALCONY GARDENS IN SPAIN.

SPAIN, though full of natural advantages, is not a country in which gardening has arrived at its highest state of development. In some parts of it leagues may be traversed without a tree being visible, and this in districts, too, where soil and climate are alike favourable to their growth. On the other hand, the Alamedas or public gardens, attached to most Spanish towns, are nearly always beautiful—beautiful from the very wealth of vegetation that too often is allowed to run riot in them. In addition to these public gardens or promenades, which are indispensable in a country in which the rays of the sun are nearly vertical and fall with an almost tropical power, Spanish towns, more especially those in the southern part of the kingdom, have a system of balcony gardening, the greenery in which serves as a relief to the long narrow streets, where the heat, radiating from the whitened houses, is inconceivably intense. Travellers in Spain, for the first time, are captivated with these street gardens, from which all manner of creeping plants depend in graceful profusion over the scorched and dusty walls. These balcony gardens

Spanish Balcony Gardening.

are usually under the especial care of the Spanish señoritas, who certainly manage to infuse into them as much beauty as is possible under such unfavourable circumstances as regards shade and moisture.

F.

HEPATICAS IN BOUQUETS.

WHEN mounted in hand or button-hole bouquets, few flowers obtainable at this season are more effective than the old-fashioned Hepatica, a plant commonly met with in nearly every cottage garden. The large single blue (or perhaps I should rather say lavender) and the double pink kinds, are the most striking. The blue contrasts well with white, yellow, scarlet, and pink, and the pink is most effective when mixed with white and blue. I have seen a handsome hand bouquet formed of white Camellias, Azaleas, Gardenias, Lily of the Valley, scarlet Geraniums, and blue Hepaticas, with the addition of Ferns. One consisting of white flowers of the same varieties as those just enumerated, with pink Hepaticas interspersed through them, had also a fine appearance. In button-hole bouquets, blue Hepaticas against a yellow Rose-bud, such as that of Maréchal Niel, look well; while the pink kind is most effective associated with maize-coloured flowers, such as Roses or Orchids. For hand bouquets, Hepaticas should be mounted on stubs in little bunches of not less than six in each bunch, and bound round their stems with a little wet Moss to

keep them fresh. In button-hole bouquets, they will not require to be mounted, as their natural stems are quite long enough for that purpose. Though the blooms of this pretty spring flower are obtainable, as I have said, in almost every old-fashioned garden, those which have been lifted from the open ground, potted and started in a greenhouse, or cold frame, are the most suitable for bouquet making, the flowers produced under glass being cleaner than those out in the beds. The latter growing, as they do, so close to the ground, are apt to get soiled, especially during heavy rains. The leaves of Hepaticas may often be used in small bouquets, being in form not unlike those of some dwarf Ivy.

A. HASSARD.

THE FLOWER GARDEN.

SUB-TROPICAL PLANTS FOR INDOOR DECORATION.

I CAN fully endorse all that your correspondent, Mr. Groom, has said in favour of these for winter decoration. Plants of fine foliage and stately growth are valuable at any season, to tone down the glare of colour and break up the uniformity and flatness which too often prevail in modern flower gardens. Valuable as they are for the above purposes, they are doubly so for forming bold groups in large conservatories, halls, &c., when other plants, even if available, are too valuable to risk in such places in the winter season. For saloons, corridors, halls, &c., they are much more effective than flowers, as they associate better with the surroundings than any plant in bloom, unless it has ample and bold foliage in addition. Few things are better adapted to this purpose than the old *Cineraria cyba*, the bold handsomely-formed leaves of which are almost equal in texture and appearance to rich velvet. Like all plants with large leaves, it is a gross feeder, and should be liberally treated, to have the foliage really fine for autumn and winter decoration. It is best, therefore, to plant it out in June in deep rich soil; and, by taking it up carefully in the autumn, the rich leaves made during the summer, which will be finer and more attractive than if grown in pots, may be easily preserved. This fine-leaved *Cineraria* is at least half hardy, and will, therefore, stand a good deal of rough usage, cold and draught, such as plants often have to put up with in halls and corridors. *Abutilon mar-moratum* makes a splendid winter plant if grown in a light warm house, as the leaves are much more delicately mottled than they are when grown out-of-doors in the summer. This variety is superior to *Thompsoni*, being more robust in growth, longer in the leaves, and more richly mottled. A bed of this, dotted over with the old *Verbena venosa*, or edged with *Viola Perfection*, is most pleasing and effective. *Aralia Sieboldii* and *Sieboldii variegata* are invaluable for standing in draughty passages or cold conservatories; indeed, their thick leathery leaves and hard woody stem render them almost indifferent to cold or light, as they will stand for weeks without injury where few other plants could exist as many days. Their beautifully cut, polished, bright green leaves are always attractive, and command admiration. The best way of obtaining these is to sow seed at once in gentle heat, and, if potted on and well treated, they soon make nice plants. *Aralia papyrifera* makes a fine stately plant, and is valuable for the centre of beds and groups, but is not equal to *Sieboldii* for hardiness of habit or general usefulness. This variety propagates readily from the roots. Large fleshy pieces of these, cut into lengths of 2 inches or so, and inserted in heat, will soon send up shoots, and form nice plants by bedding-out time. *Melanthus major* is, perhaps, one of the most useful and striking of this class of plants, and the peculiar colour and distinct form of its leaves always render it attractive. For winter decoration I find it one of the most useful, and it has such a distinctness of character that few persons pass it unnoticed. Seed of this, sown in heat now, will make plants fit for planting out in June, and be ready for lifting the following autumn. *Echeveria metallica*, if grown to a good size, makes a fine plant for vases to use in light dry places, or in connection with statuary or architectural embellishments, with which it associates well, and shows off its rigid outlines to great advantage. This, too, soon makes nice plants from seed; if sown in heat now they will make useful plants for next winter. Palms are, perhaps, the most effective of all the fine foliage plants; indeed, they are looked on as aristocrats among plants, and can scarcely be misplaced, as they associate well with other things, and impart an air of grace and lightness unequalled by anything else. Unfortunately, most of these require more warmth for their growth than that afforded by an ordinary greenhouse, and the greater part are of slow growth, and dear compared with other plants. Such varieties as *Latania borbonica*, *Areca lutescens*, *A. Baueri*, *A. sapida*, *Seaforthia elegans*, *Phoenix reclinata*, *P. dactylifera*, *Chamærops humilis*, *C. australis*, and *C. excelsa*, may be had at moderate cost, and all succeed in a greenhouse temperature.

J. S.

CHANGING THE NATURAL FORMS OF PLANTS.

VARIETY in gardening does not consist wholly, as some appear to suppose, in the number of kinds or species of plants obtained and cultivated. Diversity of form obtained by training them will frequently produce almost, if not quite, as beautiful an effect as great variety; herein lies much of what is termed skilful and successful gardening. Suppose, for instance, one has but the two varieties of the dwarf double-flowering Almonds, the white and pink. A clump of each are pretty ornaments to start with, then a change can be made by putting the pink sort in the centre of the group, and a row of white outside, and in such a position that one can look down upon the clump instead of a side view. Then this order may be reversed, or a long ribbon of pink and white may be made by planting a row of each, side by side. A far more elegant shrub is produced by budding these plants upon Peach or Plum stocks, and 4 or 5 feet from the ground. Young healthy sprouts or seedlings should be planted in spring, and the stems cut off at the desired height; and, if there are any side branches, shorten these to within 3 or 4 inches of their base. Young shoots will push, and into these the buds are to be inserted in July or August, or when in proper condition for the operation. A stock may be budded with one variety, or a few buds of the White Almond put on the centre shoots, and a row of pink on the outside. It is always a good plan to put in more buds than are desired, if all should grow, which does not always follow, even when the budding is done by a skilful hand. The white-flowered sort has quite stiff upright growing branches; but those of the pink are long and slender, and, when worked on such stocks as I have described, will bend over most gracefully, especially when loaded with flowers. The elegant appearance of such a shrub can readily be imagined if never seen by anyone who is acquainted with the plants named. Of course, I am presuming that everybody who has a garden knows how to bud and graft trees; and, if they do not, they should learn without unnecessary delay. Perhaps these few hints given will set the reader thinking how other departures from standard types may be secured; if so, everything will depend upon the persistency of the effort in that direction. Many persons, however, are prone to think that it will not answer to depart very widely from the natural "bent" of the plant; therefore, their climbing plants are always treated as climbers—never as bedding or low trailers. A Prairie Rose looks well upon a trellis, or trained to a stake, or when pegged down to the ground to form a rosy cushion only a few inches high. If weeds and Grass are likely to interfere, it is a very easy matter to cover the ground for a few feet about the main stem with gravel, old bark, or anything which will prevent the weeds growing through. All kinds of climbing plants may be treated in the same manner in order to produce a variety of ornaments. Honeysuckles trained over an old rock or heap of stone look fully as well, if not better, than when covering some costly trellis. Wistarias may be trained as low or high shrubs, although they are classed among the climbers. Because a plant naturally grows tall and slender, it does not necessarily follow that its form cannot be modified to suit our convenience or taste in the matter. By lopping off a branch here, and bending another there, natural forms may be changed without seriously interfering with natural laws; and, by a little forethought and consideration as to the effect which we desire to produce, there is little danger of falling far short of the object sought. There are usually more or less waste materials about a place which can be used to advantage in this way. The old Plum sprouts may be used as stocks upon which to work the double-flowering Almonds, Peaches, and Plums. The Cherry and Apple seedlings can also be turned to good account in the same way; in fact, stone-heaps and rubbish-piles, as well as old stumps, may be made useful as well as ornamental.—"Horticulturist."

Fuchsia Riccartoni—According to Mr. Tillery, writing in the "Gardener's Chronicle," Fuchsia Riccartoni came from Port Famine, on the Southern American coast of Terra del Fuego. In the western isles of Scotland, the south of Ireland, and the southern counties of England and Wales, it is hardy, and forms one of the finest flowering hardy shrubs that has been introduced. In a catalogue of indigenous and tropical plants which he has cultivated and kept from 1832 until this date, under the head of Fuchsias are the following old varieties:—Coccinea, introduced from Chili in 1788; lycoides, from Chili in 1796; tenella, from Chili, in 1824; virgata, from Chili, in 1825; excortica, from New Zealand, in 1825; microphylla, from Mexico, in 1828; and fulgens, from Mexico, in 1837. None of the Chili varieties are so hardy as Riccartoni, for if planted out they require covering up in severe frosty weather, even in the south of England. Globosa, conica, gracilis, and other old varieties, which he has likewise grown, are very likely to have been early garden hybrids. The Mexican varieties of Fuchsia—fulgens, serratifolia, and others—are tender, and only fit for greenhouses and conservatories.

THE FRUIT GARDEN.

RUST ON GRAPES.

THIS only affects the appearance of the fruit, without spoiling it for use. When the berries are small they are most liable to rust, but after they are thinned and stoned they are past all danger of rusting, so that no anxiety on that score need be felt when this period has been reached. It is quite perceptible at its earliest stage, and may be recognised by the speckled rough brown marks which appear to a greater or lesser extent on the berries; and these marks never leave them, nor do they change colour; when the fruit is jet black, their brown hue is still perfectly visible. Black varieties are more susceptible of rust than light ones. The Black Hamburgh, one of the most useful of varieties, is the first to become rusted. The disease, it has been alleged, is the result of not washing from the pipes the sulphur used the previous season before starting the Vines. I cannot tell in what way the sulphur effects the mischief, but I am convinced on one point—the fumes have no hand in the affair; and I do not see that sulphur sticking fast to the pipes can reach the fruit in any other way. For my own part I do not believe that sulphur has any influence in producing it, for it is only when the berries are small and tender that they are liable to rust. Now small bunches of Grapes are often allowed to form on the lateral growth of Vines when the main crop is nearly ripe, and when sulphur is needed it is applied about this time, when I have often observed that, although the sulphur fumes were strong enough to kill a strong force of red spider in two nights, the young tender berries on the lateral shoots were not injured in the slightest degree. Cold draughts of air are what I consider as the principal cause of rust on Grapes, for I have often observed that wherever rust appeared it was upon those bunches that were directly opposite a current of cold air, which, if not constantly playing upon these, was at least occasionally admitted. J. M.

Grapes Shanking.—Those who are best acquainted with Grape growing feel least certain what the primary cause of shanking is. Some varieties are more liable to shank than others; even in the case of two Vines of the same kind, planted side by side in a border in which their roots intermingle, one will sometimes shank, while the other remains sound. I have known a house of Vines, at least fifty years old, with stems at the base as thick as one's leg, which produced shanked berries year after year. Draining and protecting the borders were tried, but with no good result; as a last resource, the Vines were cut down, and young rods trained up from the old stock, and not a shanked berry has been seen since. This fact induced me to believe that I had discovered a cure for shanking; and, on being applied to for a remedy in a similar case, I related what the cutting-down plan had effected. It was, therefore, at once resorted to; but, in this case, instead of effecting a cure, the Grapes shanked, if possible worse than before. The disease appears to me to be constitutional; whatever induces healthy vigour undoubtedly tends to keep it in check.—B. W. S.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Best Filberts and How they Should be Grown.—The Cosford, the Red and the White Filbert, and the Waterloo, are the sorts I would recommend "E. A. N." (see p. 131) to plant; the last—an excellent sort—is sold possibly in other nurseries under some other name; mine came from the Chilwell Nurseries, near Nottingham. For suitable soil, &c., and mode of cultivation practised in the orchards near Maidstone, in Kent, see "Encyclopædia Britannica," seventh edition, article Horticulture, Vol. XI., page 650.—B. S.

— "E. A. N." will find the following Filberts answer his purpose, viz., the Cosford, a thin-shelled sort, very early and of the finest quality, Lambert's Filbert, and Kentish Cob—the latest and best of all the Nuts, and one which under good preservation will keep good for two years. Filberts will grow in almost any good well-drained soil; the distance between the trees should be 12 feet; height of trees 5 feet, to be kept within limits by pruning; the trees should be kept free from superfluous wood, and all suckers should be carefully eradicated. The trees will be much benefited by receiving a good solid dressing of manure every two years.—R. NISBET, *Aswarby Park*.

— In Kent Filberts are pruned yearly, and kept as bushes on one stem by allowing no suckers to grow at their roots. I have, however, never grown them in that way myself, the plantation here being formed of straggling bushes, which generally bear large crops. The following are the varieties planted out here, viz., Pearson's Dwarf Prolific, which is one of the surest of bearers, and one which ought to be planted plentifully and mixed with the others, as it always produces plenty of catkins; Red, White, and Purple and Cosford Filberts, the Kentish, and Prolific are the best of the Cob-nut section. Some of these sorts can be had grafted on the Spanish Hazel Nut, on stems 3 or 4 feet high. This stock, producing, as it does, few suckers, they can be grown into nice ornamental standards by thinning the most crowded shoots and stopping the vigorous ones. The soil of the Filbert plantation here is of a stiff loamy limestone character, and it was trenched 18 inches deep and some rotten manure put into the bottom of the trench, but no manure has been added since. The trees were planted in rows 10 feet apart and 5 feet asunder in the row, standard Plums being planted in the middle of each row.—WILLIAM TILLERY, *Welbeck*.

THE INDOOR GARDEN.

PLANTING OUT CAMELLIAS.

JUDGING from observation, I think this is the best way of growing these favourite plants. They certainly grow more freely, and are more easily kept in a healthy condition when planted out than when confined to pots, and become larger and handsomer plants. I do not remember seeing a Camellia either in a pot or otherwise which pleased me more than the large specimens in the conservatory at Chiswick House. These prove the benefit to be derived from planting out when old age comes upon them. These plants are of larger dimensions than they could possibly have attained in pots or tubs. Their growth, health, and annual bloom are wonderful. Some years ago I remember seeing some nearly equal to them at Ferguslee, near Paisley. These had been planted out for many years. In character they resembled a luxuriant Portugal Laurel, and they had been often cut back to prevent them from obstructing the pathway. They, however, continued growing, and presented a perpendicular face of foliage, equal to the best-leaved hedge I ever saw. In the flowering season they were a sheet of red, white, and other colours. Another instance came under my notice lately at Drumlanrig. The plants there are more recently planted, but their condition is most satisfactory. As they have not yet grown into each other, and become a single mass, the health and symmetry of every plant is easily observed; no vestige of bare stem was visible; the wood was clothed with healthy green foliage to the main stem. The blooms were furnished in the same luxuriant way, and for size vied with any I have ever seen. Every bush was smothered with gorgeous blooms and buds, and many of the latter had to be thinned off. Some of these plants were forced into bloom in September. In November they were as fresh as ever, scores of the first-opened flowers having been cut. Camellias in general do not force well. I never saw a plant so treated without suffering considerably. At Drumlanrig the plan adopted is very simple. The early flowering plants are out of bloom by January. They are started into growth in February, with something like a stove temperature. This heat is kept up until the young wood is strong and the flower-buds set. The temperature is then lowered by degrees until greenhouse treatment is given them throughout the summer. In October they need little inducement to come into bloom, and well they look at such a time. Camellias might be planted out in every greenhouse and conservatory that has a centre bed; nothing better could be placed in such a position, and I do not consider the fact of not being able to remove them any objection. A well-foliaged bush or clump of them is never offensive to the eye, and, when the side shelves are furnished with small plants, a bold centre is a pleasant relief. In preparing to plant out Camellias, the first matter requiring attention is the drainage. This should be ample, and nothing is better for the purpose than broken bricks. Their depth should be according to that of the bed, but at no time should less than a layer of 2 inches be considered sufficient; for a bed 2 feet deep double the quantity of drainage is not too much. Rough bits of turf or broad sods must be placed next the drainage; this prevents the finer soil from choking it; the remainder of the bed should be filled up with rich, mellow, fibrous chopped turf. If deficient in sand a little may be added. A good quantity of charcoal may be mixed in all kinds of soil. When the bed is filled the soil should not be too wet or too dry, but in much the same state as that generally used for potting. The time to plant is at that period when potting would be done—that is, after the flowering is past, and when growth has begun, but before it is too far advanced. Old plants of large size, but past their prime, may be planted out with advantage, when their vigour is generally renewed. When the roots of such are much matted, they should be disentangled as much as possible. This is an important matter, and is of immense benefit to the plants. The same remarks apply to young open-balled plants. After they are planted, watering should be delayed until the roots have begun to lay hold of the soil; this will be within a fortnight, if all goes well. During this time the house must be kept close, and shaded from strong sunshine, and the atmosphere must be

humid, with a temperature of 65° at night, and 10° more upon hot days. When the growth and flower-buds are matured, air should be gradually admitted, until the top and bottom lights are left continually open; this has the same effect as placing Camellia plants in pots outside to harden their wood. This treatment for encouraging their growth, setting the flower-buds, and ripening their wood becomes an annual practice, and their profuse blooming becomes the same. The old and valuable Double White variety and imbricata are two of the best at Drumlanrig for autumn blooming; but every kind succeeds when planted out. For this, and even other purposes, my favourite kinds are, amongst whites, Candidissima, Alba compacta, Comte de Flandres, Dionisia Poniatowski, Duchesse de Berri, Fimbriata, and Virgine di Colle Beato; reds—Adrien Lebrun, Coquetti, and Reine des Fleurs; rose—Carlotta Nencini, Comte de Thol, Contessa Mariana, Marzo, Exquisita, Corradino, Eugénie de Massena, and Elegans; other pleasing shades—Comtesse Lavinia, Maggi, Jubilee, Countess of Ellesmere, Queen of Beauties, Ninfa del Tebro, and Lady Hume's Blush.

J. MUIR.

A NEW FERNERY.

THE accompanying illustration shows a section of a Fernery erected at Langside, by Messrs. Boyd, of Paisley. Strong brick walls are carried up both sides and at one end, from which the rock-work slopes irregularly down on either side, forming a miniature ravine with a waterfall, the stream meandering round the crags and amongst the

Section of a Fernery.

stately tree Ferns. The entire building is covered by a glass roof, supported by strong iron girders, and the interior—60 feet long by 30 feet wide, and 30 feet high in the centre—is thus left without a single pillar or tie-rod, thus leaving the space wholly to the Ferns and rock-work. The latter was constructed by Mr. Pulham, and is admirably adapted for the purposes to which it is devoted. Messrs. Boyd have erected several Ferneries on this plan and, amongst others, that at Mr. J. C. Wakefield's, at Eastwood Park, the interior of which was fitted up by Mr. Blake. One at Benmore, Argyleshire, is built against a cliff in such a way that one side consists of natural rock, which, being tastefully planted with Ferns, has a fine effect.

WORMS IN POTS.

I LATELY saw a considerable number of plants re-potted, and many of the balls, when turned out of the pots, in which they had been for a long time, were completely perforated with worm-runs. The plants, as might be expected, were in a very unhealthy state, for they cannot grow successfully with worms in the soil in which they are potted. Worms are as great pests as moles in any ground; for, if they do not disturb the roots, they always carry the soil down amongst the drainage, which becomes clogged up. This in itself is sufficient to produce a very bad condition; in fact, the whole ball soon becomes

stiff and sodden with worms working in it. Fibrous loam is quickly reduced to this state by them. A sprinkling of soot spread over the drainage, before putting any soil into the pot, will prevent worms from coming up into the soil for some time; but this gradually loses its power, and does not destroy those which are in the soil when potting takes place. It is, therefore, a good plan to pick the worms from the soil before using it; a little soot mixed with it will effectually get rid of those smaller ones which may have been overlooked. Soot is a valuable fertiliser, and may with advantage be used in soil for nearly every purpose. Care should be taken that the bottoms of pots are never placed in loose soil, or any other free matter through which worms can penetrate, or your preventive measures and trouble will avail you nothing; a firm bottom of coal-ashes is the best substance to set pots on, as it resists all attempts to get through. Gravel has not the same influence, unless laid in the form of concrete. Strawberry plants in pots are often infested with worms. It is next to impossible to keep them out of these; they generally find their way into the small pots when the runners are being rooted in them. A handful of ashes under each pot will prevent their access in a great measure, but runner pots are often plunged in the soil, and they can then get in from either top or bottom. As many as are visible will, of course, be thrown out at the time of shifting, and if any still remain, the application of lime-water is the best method of destroying them. For every gallon of water half a pound of hot lime is needed; the requisite quantities should be mixed up in a tub, and well stirred up when the lime is put in. The mixture should not be used until the liquid is quite clear and the lime sunk to the bottom; each ball should then be thoroughly wetted with it, and if the first application is not effectual, the second always will be. I have seen the holes in the bottoms of the pots stuffed up, the pot filled to the brim with the lime, and allowed to remain thus for an hour. This plan kills the worms, and leaves them in the soil; I prefer leaving the holes open; it saves a great amount of labour, and the worms, when touched with the lime-water, either come to the surface, when they may be gathered, or make their way out by the drainage hole. This method of getting rid of worms is very simple, effective, and may be resorted to without the slightest danger to any kind of plants. J. MUIR.

FOUR VARIETIES OF STREPTOCARPUS.

THERE is now coming into bloom in my cool stove-house a beautiful variety of *Streptocarpus*, which I received from the Botanical Gardens, Glasnevin, where it was believed to be *S. Saundersi*—a mistaken supposition, however, inasmuch as the plant is evidently *S. polyanthus*, figured in the eighty-first volume of the "Botanical Magazine," tab. 4,850, and not *S. Saundersi*, figured in volume eighty-seven of the same work, tab. 5,251. These two varieties of this genus are what are botanically termed *Monophyllous*—that is to say, each plant produces only one leaf, which, in their case, is of great size and substance, often reaching a foot in length, and 8 or 9 inches in breadth, closely adhering to the earth, and hanging down over the side of the pot. From the base or axil of this large leaf rise the flower-scapes, which in strong plants are produced in great abundance, and usually begin to appear about this time of the year, continuing to produce their beautiful flowers for two or three months continuously. The individual blooms of *Streptocarpus polyanthus* resemble a large Violet in shape, are of a clear pure lavender colour, and are produced on tall branching foot-stalks. This species was introduced from Natal in 1853, by Captain Garden, and was raised by the merest chance, some seeds of the plant having fallen among the roots of a living Fern, where they germinated after their arrival in England. The blooms of *S. Saundersi*, which is, perhaps, the most beautiful of the four, are of a delicate greyish-blue colour, with two distinctly marked purple blotches at the opening of the throat. The three plants in one good-sized pot, from one of which the plate in the "Botanical Magazine" was prepared, had then produced no fewer than twenty-one fine spikes of bloom, and over 120 flowers were then in actual perfection. This variety was first flowered in this country by Mr. Wilson Saunders, of Reigate, after whom it is named, and to whom seeds of it were sent from Natal by Mr. Plant. The other varieties of the family as yet introduced are not *Monophyllous*, and are of much less robust habit of growth, and also much less profuse flowering than the two first described. The first of them, *S. Gardeni*, named after the introducer of the fine *S. Polyanthus*, and figured in Vol. 81 of the "Botanical Magazine," tab. 4,862, only produces two pale lilac flowers, faintly streaked with purple on each stem, while the second, *S. Rexii*, figured in the 14th volume of "Edward's Botanical Register," tab. 1,173, seldom, if ever, produces more than a single flower on each stem; its blooms, however, are of a deeper shade of lavender than those of *S. Gardeni*, and are prettily streaked with purple, and they appear continuously from six weeks to

two months; they are also individually larger and more tabular-shaped than either of the large-leaved varieties, and more resemble those of a small *Gloxinia* in their formation. *S. Rexii* will succeed in an ordinary greenhouse, and is the only one of the four commonly met with. I should be glad if any of your readers could put me in the way of obtaining either plants or seed of *S. Saundersi* or *S. Gardeni*, as both are well worth growing, but especially the former. I may add, that I have only once met with *S. Saundersi* in the collection of any nurseryman, and the plant I then obtained, having died without flowering, when I inquired for it again it could no longer be supplied.

Belgrove, Queenstown.

CULTURE OF THE DOUBLE CHINESE PRIMROSE.

IN answer to "Primula" (see p. 146), allow me to say that most of the cultural details regarding Chinese Primroses must necessarily depend upon the time at which it is desirable they should flower, and also upon the various purposes for which they are required. Nevertheless, whether they are intended as specimen plants for conservatory ornamentation during winter, or as small-sized plants for intermixing with others for room decoration, or simply as cut blooms, a purpose for which they are admirably adapted, inasmuch as they keep fresh long after being cut, your correspondent may derive some information from the following cultural remarks. As regards propagation, that may be effected by means of cuttings secured when the plants are in vigorous growth. I would therefore recommend August as the best month in which to strike cuttings of double Primulas, as plants rooted then and kept over the winter without blooming make by far the best specimens the following season. In the first place, have in readiness a close frame, in which there is a bottom-heat of about 75° previous to taking off the cuttings, as any excess of humidity, either in the shape of steam or otherwise, is to be avoided. The cuttings should be taken off with a heel, *i.e.*, with a portion of the firm wood attached to them, and inserted singly in thumb-pots, in a compost consisting of two-thirds peat, and light loam and sand in equal parts; and, if the peat be of a hungry character, a little leaf-soil may be added. Be careful, in inserting the cutting, that a portion of the silver-sand surrounds it; and, at the same time, it will be necessary to support the more vigorous growths by staking them securely, so as to prevent their falling over. Water freely, to settle the soil in the pots; and, after it is drained off and the foliage is dry, plunge them in the frame, which must be kept moderately close; at the same time, guard against damping off, and screen them from a bright sun. They will quickly and surely establish themselves, after which they must by degrees be inured to light and air until they withstand full exposure without flagging. They will then require a shift into larger pots, and must be kept in a mild temperature until established; after which, by degrees, they must be inured to a light airy pit, in which the minimum temperature does not fall below 40°, as it is not desirable to produce robust growth, so long as the plants are kept slowly growing through the winter. Be careful to pinch out the whole of the flowering shoots as they appear. If shifted on during early spring, use a somewhat rougher compost of turfy loam and leaf-soil, with a liberal admixture of sand to ensure perfect porosity. Pot moderately firm upon an efficient drainage. The plants will make rapid progress placed near the glass in a light structure. Large pots are not to be recommended, as, from the delicate nature of the roots, they thrive best when in a compact state, and are, consequently, not so liable to suffer from damp, for they quickly succumb in a soil that is at all sodden; water, therefore, should at all times be carefully administered to the roots, and 6, 7, or 8-inch pots will be sufficiently large; the latter size should be used for the strongest plants only, which are intended for conservatory adornment. As Primulas naturally delight in a somewhat shady position—that is, screened from the mid-day sun—the best situation that can be chosen for them during the summer months is a frame under shelter of a wall facing the north. The plants should be placed upon ashes, of a sufficient depth to prevent the ingress of worms, as well as to facilitate perfect drainage under the pots. Shade them from bright sunshine, and encourage vigorous growth by syringing round the sides of the frame and amongst the plants, but do not syringe the foliage, and gradually inure them to a free circulation of air, which is most desirable for promoting sturdy growth; at the same time sweeping currents of air must be avoided, as they are particularly damaging to this class of plants. Treated thus, they will make fine plants by September, when they should be removed to an airy pit, and kept close to the glass. Hitherto the flowers having been removed, an early batch should be selected, and allowed to produce bloom, which they will do in great profusion. As the double varieties are, upon the whole, more floriferous than the single, and last a longer time in flower, they should, under favour-

able circumstances, stand in good condition for at least four months. When the plants are in flower, they should be placed in a light airy position near the glass, and be subjected, if possible, to a temperature averaging 45° . Without this treatment perfect success is not to be looked for; in a light airy house only, will they produce, in full vigour, those elegant masses of blossom for which this class of plant is so highly prized. Larger plants than those I have referred to may be grown by potting on those best formed for the future season; but these rarely turn out satisfactorily, and, being very liable to damp off, are certainly not worthy of the trouble necessary to ensure even partial success. When a large quantity of plants are requisite in 4 and 5-inch pots, for furnishing trays in rooms, a portion of the stock should be propagated in spring. After the plants have finished flowering, remove the flower stems and slightly reduce the foliage; afterwards encourage fresh growth in a genial temperature for a few weeks previous to taking off the cuttings; they will then root freely in a brisk bottom-heat. If attended to as previously recommended, they will soon make strong plants, and by October, when they are placed in a growing temperature, they will have developed an abundance of flower. For the smallest-sized plants spring propagation may be resorted to; at the same time Autumn is the most favourable season for preparing for a successful start with this easily cultivated, but somewhat overlooked, class of flowers.

GEO. WESTLAND.

THE CONICAL-BERRIED SOLANUM.

(*SOLANUM CAPSICASTRUM*.)

THIS is one of our most ornamental indoor berry-bearing plants, and one which is grown by the thousand for the supply of Covent Garden market during the autumn and winter months. There are several varieties or strains of this species in cultivation, differing from one another in size, berry, dwarfness of habit, and in the profusion, or otherwise, in which the fruit is produced; and now, we believe for the first time, we may add, in the form of the berries. In our illustration, as will be seen, they are oblong or conical, and, in this respect, differ from those of any other variety with which we are acquainted. We recently saw a plant of this variety a foot high, and about the same in diameter, in the Wellington Road Nursery, profusely covered with berries, the colour of which was orange of the most brilliant description.

It was one of a batch raised from seed sown in March, 1874. The seedlings were potted on, and, about the last week in May, they were planted out on a western border. Here they received no attention, except occasional waterings until the autumn, when, just before the berries commenced to colour, they were carefully lifted, and potted in 32-sized pots. They soon formed new roots, having been kept in a close atmosphere for a few days after lifting, and when we saw the plant, from a portion of which the accompanying illustration was prepared, at Christmas last, it was loaded with berries, handsome both in shape and colour. We have no doubt that this variety of *Solanum Capsicastrum*, when better known, will become a valuable ornamental plant.

B.

Echeveria fulgens.—This ought to be better known and more extensively grown than it is, as it is one of the most useful plants for the winter decoration of the conservatory or for cutting from, continuing, as it does, long in flower at a time. It may be induced to flower any time from November to May. When wanted early, it may

be brought on in a warm pit or stove, then hardened off and taken to the conservatory, or it may be kept in a cold greenhouse all the winter, when it will flower in March. The principal thing is to keep it from damping off through the winter. When in a greenhouse it is easily managed. In order to have small useful plants, secure the cuttings of it from old plants that have been brought into flower, say in February. After making the cuttings expose them to the air for a day or so to dry the heel a little, then put them into pots in a good open soil, with plenty of sand in it, plunge them in a bottom-heat of 85° or 90° , and under a good top-heat they will strike in a short time, when they should be potted off into small 60-sized pots, using two parts loam, one part leaf mould, and one part rotten dung, with sand enough to keep all open and porous. Replace them again in heat till established, then harden them off and put them in a cold pit; when well rooted pot them off into 32 or 24-sized pots, using the soil just mentioned. Put them into the pit again until they have become established, when they should be plunged out of doors in an open place, as by this time there will be no fear of frost. During summer

they must be kept well watered, and in autumn they should be brought into a cold house and introduced into heat as required. If the old plants are potted, say in May, they make good specimens, which should be treated the same as the young ones after the second potting. When grown in 48-sized pots, these plants will be found useful for small stands, and I ought to add that they are much benefited by being watered with manure-water when coming into flower.—JNO. CROOK.

Scented-leaf Geraniums.—While Zonal, Bicolor, and Tricolor Geraniums are such favourites (says "Moore's Rural"), it is to be feared that some of the good sorts in other classes are being overlooked. When it comes to making up a bouquet in winter, a few leaves of the sweet-scented sorts work in very agreeably, especially the Rose, Lemon, and Pennyroyal. In addition to the fragrance of the leaves they are also quite showy when well grown. For instance, Lady Plymouth is a variety of the common Rose Geranium, with the leaves distinctly variegated with white, the contrast in colour being so decided that it could scarcely fail to attract attention. Then there is Apple-scented, Balm-scented, Citron, Nutmeg, Peppermint, Orange Myrrh, and (perhaps the grandest of all in appearance, at least) the Fern-leaved. This is a splendid plant, with the leaves so finely cut that they appear more like a mass of green silken

fringe than veritable leaves. The plant is a strong vigorous grower, but not coarse and straggling, like the old Rose Geranium.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Tacsonia Van-Volxemii Culture (Devon).—Merely thin out the long and bare shoots, leaving the shortest and strongest, especially those springing from the stem. Leave a good number of shoots for training-in, and what you do prune cut to within a joint of the place where they originate. See that the plant is not impoverished at the root, and allow it to luxuriate in turfy loam.

Plumbago rosea for Conservatory Decoration in Winter.—This old occupant of our stoves—now rarely met with—possesses a value as a winter-flowering plant that is worth being more generally known. When at Brocklesby Park a few weeks ago, I was surprised to see a number of plants of about 18 inches high, each with four or five spikes of flowers, employed to assist in decorating the conservatory; and on going through the plant-houses I found fifty or a hundred as a reserve stock, ready to take their places. Its flowers are produced in axillary spikes, and have a colour between rose and scarlet. They are cultivated exactly in the same way as the Poinsettia and Thyracanthus, and as winter-flowering plants have a value that agreeably astonished me.—J. C. NIVEN, *Botanic Gardens, Hull*.

A Conical-berried Solanum.

THE KITCHEN GARDEN.

SALAD GROWING UNDER CLOCHES, &c.

THERE is one particular department in gardening in which English gardeners are behind the French; I mean in the production of salads, and more especially during the winter season. There are several things that have assisted in causing this state of affairs. In the first place we are not such a salad-eating people as the French, although the demand for this kind of garden produce in this country has been, and is, continually on the increase; secondly, although our climate may not show a much lower temperature in winter, the more frequent changes from frost to thaw to which we are subject, and the much more humid state of the atmosphere in this country, are conditions so trying to vegetable life, that the growth of good salad plants is more difficult with us; lastly, the appliances generally in use in this country for growing winter salad plants are such as to prevent us producing them in the high perfection that elsewhere can be attained. Again, in France there are many plants used for salads that with us are not generally liked—for instance, blanched Chicory, which on the Continent is so largely used, finds little favour in England, few liking its flavour. In addition to Celery, Beet, and similar plants which are to be found through the season in any well-managed garden, our salads may in a great measure be said to consist of Lettuce and Endive, with Mustard and Cress; in fact, Lettuce and Endive are essentials for a salad, and it is in the production of the different varieties of these that we are behind our Continental neighbours. It is the use of the cloche that enables them to produce in such excellence their salad plants. The moment I saw the healthy comfortable appearance of the plants under these glasses I recognised their great superiority over any other contrivance of the same nature. Even the useful old hand-light, when made of iron, and constructed on the best principle, with a moveable top, is much inferior in one important respect, viz., the deficiency of the light it admits as compared with the cloche, which, when made of good clear glass, enables the plants under it to receive as much light as if they were fully exposed to the open air. Anyone who has seen Lettuce and Endive grown under them cannot fail to have noticed how much sturdier in growth the plants are than those grown in frames. This is owing to the uninterrupted light they receive in every direction. The importance of light to most cultivated plants is admitted on all hands, yet we do not appear to realise the necessity of affording plants grown under glass coverings the greatest amount possible of this life-giving element, which to plants composed of soft, watery tissues, such as those under consideration, is even more necessary to enable them to withstand the incessant fluctuations of our variable climate than it is to those kept out of the reach of frost or damp. Several contrivances have made their appearance besides the ordinary garden frame, in the shape of small frames, some with earthenware sides and ends, made to take to pieces easily, and with glass to cover them in; others are made of wood; but the common fault of all these is that they only give light from above, whereas the cloche admits it all round. Light is the great compensator for the deficiency of air, which plants cultivated under glass must of necessity be subject to; and for such plants as can be grown under it the cloche has no equal, admitting as it does a full volume of light, and enabling salad plants, which the French gardeners grow under them, to thrive with the comparatively small amount of air they receive throughout the winter. To grow these plants well they require something more than the mere care that will suffice to keep them alive. There must be constant attention to produce salad materials in good condition every day in the year, especially through the winter months. One objection raised against the cloche is their liability to break; but surely this is anything but a reasonable objection, for it might be raised more or less against all the light-admitting appliances that gardeners have to deal with. If reasonable care be used there need be no serious amount of breakage.

Lettuce

being the principal article in a salad, either summer or winter, it becomes a matter for consideration how to produce them in the best condition, and also how to procure them, without interruption, all the year round. We will suppose that there is at the commencement of the year a good quantity of Black Seeded Bath Cos and Hammer-smith Hardy Green Lettuce planted in cloches, frames, and under the shelter of south walls, for spring use. Those under cover must have air in abundance on all favourable occasions, especially such as are in the ordinary frames, for they will be much more disposed to draw up weakly than those in the cloches; all must be protected with litter in severe frost, but, the winter past, they must be exposed to the open air. There should also be a good supply of autumn-sown London or some other favourite form of Cos Lettuce, in a tightly-glazed, dry, snug frame, well raised at the back so as to prevent drip

the soil filled in to within 8 or 10 inches of the glass, and dry on the surface, to avoid damping or injury from the effects of being slightly frozen should frost reach the plants. They should stand a couple of inches apart, and will require plenty of air on all days when it does not freeze. To avoid any chance of damage from this source enough litter must be provided to cover the sides of the frame and lights, over which mats should be placed and secured, so that they will not be disturbed by the wind. During the mild clear days which we frequently get through the winter the lights should be altogether taken off to keep the plants stout and dwarf, the object being not to promote growth, but to have them in as hardy a state as possible at the time of planting out. In order to secure this condition care must be taken that when the lights are thus temporarily taken off the plants are not caught by showers, neither must water be given until the time of turning out approaches. About the first week in February make a sowing of the Cos Lettuce in boxes, in a little heat, and also of Tom Thumb or Tennis Ball, keeping the plants, as soon as they are up, as close to the glass as possible, with air every day. So soon as they are big enough to handle they should be pricked out in rich soil, 3 inches apart, in large boxes, and when well established removed to a cold pit, where they can receive plenty of light and air, so as to harden them; make another sowing a fortnight later, to take the place of these should any untoward mishap occur to the previous sowing; treat them in all respects similarly. These winter-sown plants are to succeed the frame autumn-sown ones. By the middle of March a slight sowing should be made in a cold frame or under a couple of hand-lights, treating them when up so as to promote a hardy condition of growth; towards the end of the month a sowing should be made in the open air in a sheltered place. A piece of dry highly-manured ground should be now prepared, such as has been cropped with Celery, which is an excellent preparatory crop for Lettuce. The last week in the month a portion of the autumn-sown frame plants should be planted out on the prepared ground, but do not risk the whole of them, as sometimes these early turned-out plants get cut off. A portion of the

Cloche, with ventilating aperture at top.

first lot of indoor-sown winter plants should also be planted out in ground similarly prepared, especially the small Tom Thumb variety, as, if it succeeds, it will come in quicker than the Cos, and will frequently fill up the gap that might occur between the hardy varieties that have been in cloches or frames, and in the open air. The first week in April plant out another lot, and some more by the middle of the month; in the last week sow in the open air both Summer Cos and Tom Thumb, and plant out some of those sown in the cold frame or under handlights, which by this time should be ready. The outside winter plants will, through this month and the next, be ready for use; and from this time until winter the matter of supply is simple enough if two or three things be observed—to sow once a fortnight in well-prepared highly-manured ground; from this time through the summer always sowing in rows where the plants are to be grown, thinning them out as required, but never putting trust in such as have been transplanted, which are much more liable to run to seed than those sown where they are to remain. If the rows are sown in shallow trenches that will admit of their being thoroughly soaked with water in dry weather, it will be found the best means of supplying them with the large quantities they must have to grow them crisp, and prevent their running to seed. The repeated winter and early spring sowings under the protection advised may appear more than required, and so they may turn out to be in a season when all succeed; but to secure a continuous crop of Lettuce, it is necessary to provide for failures. In most places the Cos varieties are preferred to any of the Cabbage kinds, consequently during the summer season the sowing may be confined to the former sorts; but it is not a bad plan to make a small sowing once in three weeks of the Neapolitan, or some similar Cabbage variety, which will frequently fill up a gap. The best Cos Lettuce that I have found to come into use from the middle of July through August and September is William's Alexandra; it is closer and stands longer before running to seed than any other I have tried. About the beginning of August sow a little Tom Thumb and green Hammer-smith, and repeat the operation every three weeks until the end of October; sow also some Cos, and keep the earliest planted out for autumn use for the open ground, or, where there is danger of frost, for removal into frames, where they can be protected. At this season the Tom Thumb sort comes in well, occupying little room, and consequently admitting of being planted closely, as it is firm and crisp. In October the winter frame should again be got ready, as in the

previous autumn, and sown. If a little seed be put in twice during the month, it will be all the more certain of avoiding any blanks; it is the sowings in the open ground that must be depended upon for the late winter and earliest spring supply, and it is for these that the cloche is so superior to any other appliance for wintering them in. They should be placed close together in rows, with space to walk between, and litter at hand to cover them up in severe weather. In the autumn season, as well as in the early spring, there is nothing like making sowings enough to secure an uninterrupted supply.

Endive.

Both the green-curved and the Batavian variety stand next the Lettuce in importance for autumn and winter salads; but, grown as well as it is possible to grow them, they are much inferior to well-grown crisp Lettuce, except as regards appearance, which, in the curled varieties, is very fine. If seeds of the green-curved and broad-leaved Batavian varieties are put in at the beginning of July, and three other sowings of each sort are made at intervals of three weeks, they will furnish a sufficient supply. As soon as the plants of the first sowing are large enough to handle, they should be planted out in well-prepared soil a foot asunder each way; and the second and third sowings treated in like manner, the last sowing being planted closer, where they can be protected with frames when required, and some planted so as to be covered with cloches, which, as a means of protection for these late plants, are unequalled. As winter approaches, the plants of the second and third sowings, which will be large enough for use, should be taken up and planted in cold frames as close as possible without overcrowding, and here they can be blanched as required.

Mustard, Cress, and Radishes.

Mustard, although not required in such quantity for salads as Lettuce and Endive, is still very useful, especially in the winter and early spring. Its cultivation is so simple and well known as not to require further notice than to say that at all times of the year it should have a rich soil, which not only grows it much crisper, but less hot and pungent. In the winter, in forcing, the soil should be changed in the boxes every time fresh seed is sown. Cress is not so much in request as Mustard, but some people like the flavour of a little. It is not so easily grown as Mustard, but requires similar treatment; the plain-leaved is the best. Radishes are indispensable through a great portion of the year. These should be sown out-of-doors in sheltered situations at the close of the year in dry well-manured soil, the seed being covered with litter, which is allowed to remain on until the seed has vegetated, when it must be taken off every mild day and replaced in the evening. As soon as the first sowings appear above ground make a second, treating it similarly; the third sowing will possibly not require covering with litter. These earliest sowings should consist of any of the long early kinds, and may be followed by the scarlet and white olive-shaped varieties, which, when the seed can be had true, are far superior to either the Turnip or the long varieties—that is, when they are well grown in rich soil, with sufficient room to prevent their being drawn, and with plenty of water in dry weather, so as to bring them on as quickly as possible—for this is the principal point in the cultivation of a good and tender Radish. To have them in good order they must be sown every ten days through the summer, and in hot weather the seed will require plenty of water to make it vegetate. At the commencement of the year a sowing should be made on a slight hotbed. The frame, unless a very shallow one, should be filled up inside with the fermenting materials to within a foot of the glass; on this should be put 6 inches of soil, in which sow the seed. It is necessary to keep them thus near the glass, because, if severe weather should follow when they are up, enough air cannot be given to prevent drawing, which spoils them. To avoid this, they must be thinned whilst small, so as to allow them sufficient room; a successional sowing in frames should be made every three weeks, until the middle of March, after which the outside crops will come in. To succeed the outdoor sowing in the autumn it will again be necessary to resort to frame culture, sowing every month from the middle of September to December; for these early and late sowings, either in frames or the open air, the olive varieties are little inferior to the short-topped long-rooted kinds. My own practice has been to mix the seed, and sow both together. Where there is no convenience for growing Watercresses, the American or land Cress will be found useful in the spring, making a couple of sowings the first and third weeks in September, and putting the seed in a dry warm border in rows a foot apart, with a little Corn salad, which may be similarly treated as to soil, situation, and distance apart.

Beet and Celery.

Beet, which adds so much to the appearance of a salad, as well as in reality being one of the most wholesome vegetables that can be eaten, can, without much difficulty, be had all the year round where

a good cool root shed is at command, for in such a place last year's roots will keep almost until the new crop is large enough to use; but a good variety, possessing a dark colour in the root, should be selected. Many of the vaunted new kinds have the colour in the wrong place, *i. e.*, the leaves instead of the roots. A large growing sort should never be used. A salad should not be considered complete, from the beginning of September until the end of March, without Celery; but to have this dependence must not be placed on most of the coarse hollow varieties so generally met with; one or two really good sorts are sufficient to furnish a supply for the above period. It may be had much earlier if desired, but it is then more a name than a reality, not being either required or worth the trouble when there is plenty of other things in season. For the last fifteen years I have only used one kind, a pink sort, sowing in a little heat the first and last week in February, and, as soon as the plants are large enough, pricking them out in cold frames 4 inches apart in good rich soil 4 inches thick, on a hard bottom of ashes, and planting out for the earliest the last week in May in double rows, a foot apart each way, in well-prepared 3-foot wide trenches, with 5 feet of space between each trench. The plants required for winter and spring may stand in the bed where they are first pricked out until the end of June (and never allowed to suffer for want of water), when they are planted out in single rows, and not earthed up until there is danger of frost, from which it is protected through the winter. The whole is thoroughly soaked with water once a week in dry weather; and for many years I have never had it run in the least before the commencement of April. Immense quantities of worthless Celery seed is sold—hollow, stringy, strong-flavoured, and not worth cultivation. A great deal of error exists as to heavy manuring and high culture having an influence in causing a hollow growth. Nothing can be more erroneous; if the variety be right, and it be grown in rich soil, and plentifully supplied with water, there need be no apprehension of its not being solid, crisp, and well flavoured. If Celery be sown at the time above-mentioned, and treated as described, and it is found that it will not keep until April, the kind is not good; of course, I am now speaking of pink or red varieties, which are, as is well known, better keepers than the white. The method of cultivation described, and the varieties of plants above enumerated, are such as I have for a number of years employed to furnish a salad for every day in the year. It requires forethought, care and attention, if the materials are to be produced without interruption, and in a condition to deserve the name of salad. English gardeners are frequently reminded that they are behind the French in the cultivation of salads; but those who indulge in the taunt should recollect that a gardener, in even a small-sized place in England, has often an inadequate supply of labour, and has his attention unavoidably divided by a dozen things for every one the French grower has to cultivate. There is no plant so easily managed, or that will go so far in assisting to make up for a deficiency of Lettuce or Endive, as Chicory, for a family that will use it. It is of the easiest growth; the seed is sown in rows in May, thinned out to 8 or 10 inches apart, simply kept clear from weeds, taken up in the autumn, and placed in the root-shed, covered with soil or ashes in the usual way; and, when required, placed in pots or boxes, and brought on in the dark, similarly to Seakale. It is easily forced, and has a very fine appearance. Tarragon, Sorrel, Onions, and Chives are also by some used more or less in salads, and they are also employed in small quantities for flavouring. T. BAINES.

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Sulham Prize Pink Celery.—I quite agree with Mr. Gilbert respecting the merits of this Celery, and have no hesitation in pronouncing it the best pink variety in cultivation. I have about 800 heads of it still to lift. I find it particularly sound, crisp, and in flavour all that can be desired.—E. BENNETT, Hatfield.

Drain Gratings for Gravel Walks.—I would advise your correspondent, "S" (see p. 146), to have his grids or gratings for taking the surface water from his walks made in the same way as those we have in use here. I always had an objection to stone or wood frames to gratings, showing themselves as without them in a very simple and efficient way, by combining an iron frame they do, conspicuously along the sides of walks, and have contrived to do with the grating, and having the bars rivetted in, if of wrought iron, or cast with the frame, if cast iron is used. The wrought frame is made of common bar iron, 2 inches or so wide and a quarter of an inch thick; and in this the bars are rivetted level with the edge. By placing these on the top of the bricks, which form the cesspools or eyes, the gravel lays close up to the iron frame, and as this is only about 4½ by 5 inches, it is scarcely observed. The 2 inches deep of gravel surrounding the iron frame keeps all firm and immovable. In laying the bricks for the cesspool, care must, of course, be taken to have the inside just a trifle smaller than the frame, or so that the inside of the cesspool corresponds in size with the inside of the frame, and, when laid, the top of the grating should be slightly lower than the surface of the gravel, so as to admit the water freely. Gratings of this kind, if required in quantity, can be had at a cheap rate if cast, and, as they require no wood or stone frames, they cost less and are much neater than those furnished with such appendages.—J. SHEPPARD, Woolverstone Park, Ipswich.

THE GARDEN FLORA.

THE SNOWFLAKES.

(LEUCOJUM.)

THERE is—as, indeed, there ought to be—a tolerably close relationship between Snowflakes and Snowdrops. With the latter we are more familiar in cultivation than with the former, although it is said to be naturalised in one locality in the south of England. As will be seen by the illustration, the aspect of the *Leucojum* is so similar to that of the Snowdrop, that it might be taken for a larger form of it. Those, however, who are accustomed to observe, will readily detect distinctive characters; first, we have the dark green of the leaf altogether devoid of the glaucous hue; broader than even the Crimean Snowdrop, shorter and much more rigid; then, besides the broad campanulate shape of the flower, we have blotches near the tip of the petals, at first yellow, then shading off to green as they reach maturity—a peculiarity not to be found in the Snowdrop; added to these two distinctive characteristics, the Snowflake is scented, hence, possibly, we may trace the origin of the name given to it by our old herbalists, to whom it was always known as “the bulbous white Violet” a term, indeed, embodied in its generic title, which literally means white Violet. The spring Snowflake blossoms about the middle of March—or fully a month behind the Snowdrop—its flowers are produced singly on stems about 6 inches high, it is quite as hardy as the Snowdrop, and grows

Spring Snowflake.

Summer Snowflake.

freely in any ordinary garden soil—these important qualifications, supplemented by its intrinsic beauty, which a glance at the accompanying illustration will at once confirm, render this a most desirable plant, and one worthy of much more extended culture than it at present enjoys. It is a native of Germany, and is, in fact, pretty well distributed through Southern Europe, where it is found in moist upland meadows and woods. There is a variety known by the title of *carpathicum*, which, to my mind, is sufficiently distinct to rank as a species; its bulb is twice the size of our plant, its stature considerably greater, and it frequently produces its flowers in pairs. As the name indicates, this variety or species is a native of the Carpathian Mountains, and it is rare in cultivation. A double variety is also recorded under the title of *L. vernum, multiplex*—this, however, I have never yet seen. Our plate is taken from Wooster's “Alpine Plants,” published by Messrs. Bell & Daldy.

L. *aestivum*.—The Summer Snowflake is not only an old and valued garden plant, but is really a native of this country, though by no means very generally distributed; it occurs in several widely distant localities. I have myself found it growing somewhat abundantly in the Berkshire portion of the Valley of the Thames. As compared with its vernal ally, it is three times its height, as regards both foliage and flower-stems. The flowers are, however, very much smaller, and produced in groups of three or four; in shape they are less campanulate, and, in fact, so like the Snowdrop itself, that were it not for the difference in growth they might readily be mistaken for such, and a very pretty link they make, by

which early spring associations are prolonged into summer. It blooms in the latter end of May or early in June, is amenable to almost any soil and situation, and hence should have a place in every garden.

L. *pulchellum* has been considered by some as an intermediate form between the Carpathian and the Summer Snowflakes; it has, I think, full claim to be considered a distinct species; its leaves and flower-scapes attain a height of 12 to 14 inches, differing from the last chiefly in the greater breadth of leaf, the blunter point, and the more campanulate flower with the greenish-yellow blotch more distinctly defined. It is a native of moist ground in the South of Europe, and comes into bloom fully a month before the former species. Besides these—which may be said to include all the species at present in cultivation that, strictly speaking, come under the generic title *Leucojum*, as now recognised by botanists—we have a little group of exceedingly interesting plants, formerly *Leucojums*, but now constituted a genus by themselves under the title of *Acis*. These consist of the several species, *A. autumnalis*, *A. roseus*, *A. trichophyllus*, and *A. grandiflorus*. They all have slender exserted styles, very narrow leaves, scarcely attaining a height of 4 or 5 inches; pretty white or rosy drooping flowers, sometimes produced before the leaves are developed, and are natives of Southern Spain, Corsica, and North Africa. They are all more or less delicate; by this I do not mean absolutely tender, but rather that they require careful culture, and will only thrive in a light sandy or peaty soil. As a rule, they have a decided objection to pot culture, and will be found more at home in an undisturbed sunny corner of a rockery, where the previous provision of suitable soil has been made beforehand.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Herb Beds.—The space allotted to herbs in a well regulated garden is not the least important part; yet it often happens that these necessary plants are met with in a condition that might lead us to suppose that they are left, unaided, to struggle with the weeds for an existence. In selecting ground for the cultivation of these plants, choose a place that is totally free from Couch Grass, Bindweed, or anything of a deep-rooting nature that cannot be removed without deeply stirring the ground. If care in this respect be not taken, it will be found that, however carefully the ground is forked over before planting, some of the roots will escape notice, and be a source of continual annoyance. Select the most convenient spot for access, for something will be wanted from it almost every day; and, if situated in an out-of-the-way corner, the labour of gathering is much increased. The space required by herbs varies very much, but, in most cases, it is small. It is well, however, to be on the right side, and have enough. Mint is wanted more generally than most herbs, and sufficient should be grown to supply all demands from the open ground through the spring and summer, and to furnish a stock for forcing in boxes in winter. If well managed, 10 or 12 square yards will grow a good deal. In preparing the ground, which should be open, and not too heavy, dig in 3 inches of manure, unless it has been well enriched for former crops, in which case half that quantity will suffice; for this, as for all other crops, thoroughly pulverise the soil in digging, not turning it over in thick spits, and merely breaking the surface smooth, whilst the under portion is left in great lumps that are not in a condition for the roots of any vegetable to penetrate freely. When the space is dug, and if the ground is in a sufficiently dry state, remove 2 inches of soil from the surface to the alleys; then, with a fork, move from the old bed, which we will suppose is in existence, a sufficient quantity of roots to plant the new ground. If the ground already occupied is thickly crowded with roots, there will be enough in each square yard to plant three of the new. Place these evenly over the surface, and then cover with the soil that was removed, not treading upon the ground, after it is dug at this early season, more than is necessary, for, if compressed with the feet whilst wet, no crop will succeed well. To enable the amateur to put in his crops without thus treading down the ground, a few deal boards will be of the greatest use in planting Potatoes, Peas, Beans, Cabbages, or anything that is grown in rows, the edge of the boards answering instead of a line, and being equal to it in every way. These boards should be an inch in thickness, 10 or 11 inches wide, and about 12 feet in length. If longer than this, they will not be so handy to move about. Spruce is the best, not being so liable to split as Pine; and, as an additional guard against

LEUCOJUM VERNUM.

splitting, thin battens, 3 inches wide, may be nailed across the ends. It will be as well to leave a portion of the old Mint bed standing until the autumn, as the newly-planted material will not bear so much or so early the first year. When the season is over, the old roots can be taken up for forcing during the ensuing winter. Pot Majoram should be planted in rows a foot apart each way, leaving the crowns just level with the surface of the soil, the plants being made from division of the old plants. Tarragon requires similar treatment. Sage is best increased by cuttings formed of good-sized pieces of the branches, inserted about 6 inches deep in the ground, in April or September, and, if any such exist, they may be planted a foot apart in the rows and 15 inches between the rows. Thyme plants that were raised from seed sown last spring may now be planted a foot apart each way. Lemon Thyme may be increased by division of the roots; Sweet Marjoram, Basil, and Savory are raised from seed sown later in the spring. These are the principal herbs required, and the main thing to be observed in their future culture, so as to make the herb ground productive and tidy in appearance, is never to allow weeds to remain in it so as to seed and interfere with the growth of the plants, and not to let any herbs stand until they become too old, but to put in cuttings in time to replace them before they become useless. A blank in the supply is thus avoided.

Peas, Broad Beans, and Radishes.—In parts of the country where the soil is cold, and where it is useless to sow even the first crops of Peas, Broad Beans, and Radishes at the commencement of the year, seeds of these should now be put in. In sowing Peas in such land, especially if in a garden comparatively new, where nothing has been added to the natural soil to lighten it, they should be sown a little below the surface, doing no more than levelling where the rows are to be, and covering the seed with 3 inches of light open soil, half of which may consist of decayed vegetable matter from the refuse heap. When this is used, however, care must be taken that sufficient lime has been added to kill the slugs, or they will destroy the crop. These Peas will succeed those sown under glass at the close of last month. Beans, in similar land, may be planted a couple of inches deep; for Radishes the surface should be raked so as to level it, and the seed covered with half an inch of sifted soil.

Shrubberies.—In the shrubbery and its surroundings the state and position of deciduous trees should be inspected, especially those planted near the boundary with a view to give shelter or privacy. It is a matter of frequent occurrence to find such trees planted without the slightest regard to the space they will ultimately occupy, and merely placed so as to give immediate effect. Even where the trees have been planted with a due regard to their future proportions, and the intervening spaces filled with others to act as nurses for those intended to be permanent, there is nothing so common as to see the nurse plants retained until they have completely ruined the trees by crowding. The whole of the under branches, which were intended to act as a break, and upon the vigorous presence of which the beauty of the trees depended, are completely destroyed. The object of these nurse trees is only to afford the necessary shelter to those intended to stand, and to assist in filling up the intervening spaces. These temporarily planted trees should, the moment they interfere with the well-being of the others, be either removed altogether, or cut in with no sparing hand. It is often considered time enough to do this when the branches touch; but this is a mistake, for, when they have grown to this condition, very serious harm will have occurred to the permanent trees from the exclusion of light and air, thus making them draw up weakly, and rendering them unable to develop their proper growth. Thousands of amateurs' gardens throughout the country suffer in this way. The present is a good time for reducing the branches, unless the trees are still of a size to be removed, and it is the intention to replant them; in which case no time must be lost, as the buds of many will soon begin to swell.

Natural Beauty.—All our moral feelings are so interwoven with our intellectual powers, that we cannot affect the one without in some degree addressing the other; and, in all high ideas of beauty, it is more than probable that much of the pleasure depends on delicate and untraceable perceptions of fitness, propriety, and relation, which are purely intellectual, and through which we arrive at our noblest ideas of what is commonly and rightly called intellectual beauty. Ideas of beauty are among the noblest which can be presented to the mind, invariably exalting and purifying it according to their degree. And it would appear that we are intended by the Deity to be constantly under their influence, because there is not one single object in Nature which is not capable of conveying them, and which, to the rightly-perceiving mind, does not present an incalculably greater number of beautiful than of deformed parts.—
RUSKIN.

THE NATURAL HISTORY OF THE NEW VINE PEST.

By C. V. RILEY, State Entomologist, Missouri.

[THE accounts of this pest hitherto published have been so numerous and at the same time so imperfect, that we gladly publish the following exhaustive article on the subject, which has been specially revised and corrected by the author for THE GARDEN.]

The first published reference to this insect was made in the year 1856, by Dr. Asa Fitch, the State Entomologist of New York, who subsequently described the gall-inhabiting type of it (which I have termed *gallicola* in a rather insufficient manner) by the name of *Pemphigus vitifoliae*. Dr. Fitch knew very little of the insect, as we understand it to-day. It was subsequently treated of by several American authors, and in January, 1867, Dr. Henry Shimer, of Mount Carroll, Ill., proposed for it a new family (*Daktylosphaeridae*), which has not been accepted by homopterists, for the reason that it was founded on characters of no family value. All these authors referred to the leaf-louse described by Dr. Fitch, and never dreamed that the insect existed in another type on the roots. During the few years following our civil war, a serious disease of the Grape Vine began to attract attention in France, and soon caused so much alarm that the Minister of Agriculture and Commerce in that country offered a prize of 20,000 francs for an effectual and practical remedy; and a special committee was appointed to draw up a programme of conditions, and award the prize if it saw fit so to do. The disease was at first designated as *pourridie*, or rotting, the roots becoming swollen and bloated, and finally wasting away. There were no end of surmises and theories as to its cause, until Prof. J. E. Planchon, of Montpellier, in July, 1868, announced that it was due to the puncture of a minute insect belonging to the plant-louse family (*Aphididae*), and bearing a close resemblance to our gall-louse. The insect was subsequently described, by the same author, from the apterous form, under the name of *Rhizaphis vastatrix*, and not till September of the same year, when the winged insect was discovered, did he give it the name by which it is now so well known. In January, 1869, Prof. J. O. Westwood, of Oxford, announced the receipt of both the gall and root-inhabiting types, from different parts of England and Ireland, and his inability to distinguish between the two. In the same article he announced having received the gall-making type from Hammett in 1863, and having described it by the name of *Peritymbia vitisana*, in a notice communicated to the Ashmolean Society of Oxford, in the spring of 1868, which communication was, however, never published. In the spring of 1869, M. J. Lichtenstein, of Montpellier, first hazarded the opinion that the *Phylloxera*, which was attracting so much attention in Europe, was identical with the American insect described by Dr. Fitch. This opinion gave an additional interest to our insect, and I succeeded in 1870, while the Franco-Prussian war was at its highest, and just before the investment of Paris, in establishing the identity of their gall-insect with ours, through correspondence with, and specimens sent to, Dr. V. Signoret, of that city. During the same year I also established the identity of the gall and root-inhabiting types, by showing that in the fall of the year the last brood of gall-lice betake themselves to the roots and hibernate thereon. In 1871 I visited France and studied their insect in the field; and in the fall of that year, after making more extended observations here, I was able to give absolute proof of the identity of the two insects, and to make other discoveries, which not only interested our friends abroad but were of vital importance to our own Grape growers, especially in the Mississippi Valley. I have given every reason to believe that the failure of the European Vine (*Vitis vinifera*), when planted here, the partial failure of many hybrids with the European *vinifera*, and the deterioration and death of many of the more tender-rooted native varieties, are mainly owing to the injurious work of this insidious little root-louse. It had been at its destructive work for years, producing injury, the true cause of which was never suspected until the publication of the article in my fourth report. I also showed that some of our native varieties enjoyed relative immunity from the insects' attacks, and urged their use for stocks, as a means of re-establishing the blighted Vineyards of Southern France. The disease continued to spread in Europe, and became so calamitous in the last-named country that the French Academy of Sciences appointed a standing *Phylloxera* Committee. It has also attracted much attention in Portugal, Austria, and Germany, and in England where it affects hothouse Grapes. The literature of the subject grew to such vast proportions that, after publishing a biographical review, containing notices and summaries of 482 articles or treatises, published during the four years of 1868-71, MM. Planchon and Lichtenstein gave up the continuance of the work as impracticable. At the suggestion and with the co-operation of the Société Centrale d'Agriculture de l'Hérault, the French Minister of Agriculture last autumn commissioned Prof. Planchon to visit this country and learn all he could about the insect and its effect on our

different Vines. Prof. Planchon arrived here the latter part of August and remained over a month, during which time he visited many prominent Vineyards in the Eastern States, on Kelly's Island, in Missouri, and in North Carolina. His investigations not only fully corroborated all my previous conclusions regarding the Phylloxera, but gave him a knowledge of the quality of our native Grapes and wines which will be very apt to dispel much of the prejudice against them that has so universally possessed his countrymen, who have not followed our recent rapid progress in viticulture and viniculture, but found their opinions on the inferior results which attended the infancy of those industries in America. Such, in brief, is the history of the Grape Phylloxera. Let us now take a closer insight into the nature of this insect. The genus *Phylloxera* is characterised by having three-jointed antennæ, the third or terminal much the longest, and by carrying its wings overlapping flat on the back instead of roof-fashion. It belongs to the whole-winged bugs (Homoptera), and osculates between two great families of that sub-order—the plant-lice (Aphidæ) on the one hand and the bark-lice (Coccidæ) on the other. In the one-jointed tarsus of the larva or newly-hatched louse, and in being always oviparous, it shows its affinities with the latter family, but in the two-jointed tarsus of the more mature individuals, and in all other characters, it is essentially aphididan. "In every department of natural history a species is occasionally found which forms the connecting link between the two genera, rendering it doubtful under which genus it should properly be arranged. Under such circumstances the naturalist is obliged to ascertain, by careful examination, the various predominating characteristics, and finally place it under the genus to which it bears the closest affinity in all its details." So wrote Audubon and Bachman twenty-eight years ago; and what is true of genera is equally true of species, families, and of still higher

Fig. 1. Under side of Leaf covered with Galls.

groups. In the deepest sense all Nature is a whole, and all her multitudinous forms of animal and vegetable life are so closely interlinked, and graduate into each other so insensibly, that in founding divisions on two trivial differences we subvert the objects of classification. Thus, instead of founding a new family for this insect, as Dr. Shimer did, and there seems a tendency on the part of others to do, it is both more consonant with previous custom, and more sensible in every way, to retain it among the Aphidæ. Not the least interesting feature in the economy of our Phylloxera, are the different phases or forms under which it presents itself. Among these forms are two constant types which have led many to suppose that we have to do with two species. The one type which I have, for convenience, called *gallicola*, lives in galls on the leaves; the other, which I have called *radicicola*, on swellings of the roots. The subjoined table will assist to a clear understanding of what follows:

Type 1. *Gallicola*.—(Vitifoliæ, Fitch; Fig. 3, f, g, h.)

Type 2. *Radicicola*.—

a, degraded or Wingless Form. (Fig. 4, e, f, g.)

B, Perfect or Winged Form. (Fig. 5, g, h. Fig. 7, b.)

The *Gallicola*, or Gall-inhabiting Type.

The gall or excrescence produced by this insect is simply a fleshy swelling of the under side of the leaf, more or less wrinkled and hairy, with a corresponding depression of the upper side, the margin of the cup being fuzzy, and drawn together so as to form a fimbriated mouth. It is usually cup-shaped, but sometimes greatly elongated or purse-shaped (fig 2, a, b). Soon after the first Vine-leaves that put out in the spring have fully expanded, a few scattering galls may be found, mostly on the lower leaves, nearest the ground. These vernal

galls are usually large (of the size of an ordinary Pea), and the normal green is often blushed with rose where exposed to the light of the sun. On carefully opening one of them (fig. 3, d) we shall find the mother-louse diligently at work surrounding herself with pale-yellow eggs of an elongate oval form, scarcely .01 inch long, and not quite half as thick (fig. 3, c). She is about .03 inch long, generally spherical in shape, of a dull orange colour, and looks not unlike an immature seed of the common Purslane. At times, by the elongation of the abdomen, the shape assumes, more or less perfectly, the pyriform. Her members are all dusky, and so short compared to

Fig. 2.—a and b, elongated galls; c and d, upper and under side of abortive galls.

her swollen body, that she appears very clumsy, and undoubtedly would be outside of her gall, which she never has occasion to quit, and which serves her alike as dwelling-house and coffin. More carefully examined, her skin is seen to be shagreened or minutely granulated and furnished with rows of minute hairs. The eggs begin to hatch, when six or eight days old, into active little oval, hexapod beings, which differ from their mother in their brighter yellow colour and more perfect legs and antennæ, the tarsi being furnished with long, pliant hairs, terminating in a more or less distinct globule. These hairs were called *digituli* by Dr. Shimer, and they lose their globular tips and become more or less worn with age. In hatching, the eggs split longitudinally from the anterior end, and the young louse, whose pale yellow is in strong contrast with the more dusky colour of the egg-shell, escapes in the course of two minutes. Issuing from the mouth of the gall, these young lice scatter over the Vine, most of them finding their way to the tender terminal leaves, where they settle in the downy bed which the tomentose nature of these leaves affords, and commence pumping up and appropriating the sap. The tongue-sheath is blunt and heavy, but the tongue proper—consisting of three brown, elastic, and wiry filaments, which, united, make so fine a thread as scarcely to be visible with the strongest microscope—is sharp, and easily run under the parenchyma of the leaf. Its puncture causes a curious change in the tissues of the leaf, the growth being so stimulated that the under side bulges and thickens, while the down on the upper side increases in a circle around the louse, and finally hides and covers it as it recedes more and more within the deepening cavity. Sometimes the lice are so crowded that two occupy the same gall. If, from the premature death of the louse, or other cause, the gall becomes abortive before being completed, then the circle of thickened down or fuzz enlarges with the expansion of the leaf, and remains (fig. 2, c) to tell the tale of the futile effort. Otherwise, in a few days the gall is formed, and the inheld louse, which, while eating its way into house and home, was also growing apace, begins a parthenogenetic maternity by the deposition of fertile eggs, as her immediate parent had done before. She increases in bulk with pregnancy, and one egg follows another in quick succession, until the gall is crowded. The mother dies and shrivels, and the young, as they hatch, issue and found new galls. This process continues during the summer until the fifth or sixth generation. Every egg brings forth a fertile female, which soon becomes wonderfully prolific. The number of eggs found in a single gall averages about 200; yet it will sometimes reach as many as 500, and, if Dr. Shimer's observations can be relied on, it may even reach 5,000. I have never found any such number myself; but, even supposing there are but five generations during the year, and taking the lowest of the above figures, the immense prolificacy of the species becomes manifest. Small as the animal is, the product of a single year, even at this low estimate, would encircle the earth over thirty times if placed in a continuous line, each individual touching the end of another. Well it is for us that they are not permitted to multiply in this geometrical ratio! Nevertheless, as summer advances, they do frequently become prodigiously multiplied, completely covering the leaves with their galls, and settling on the tendrils, leaf-stalks, and tender branches, where they also form knots and rounded excrescences (fig. 3, e), much resembling those made on the roots. In such a case, the Vine loses its leaves prematurely. Usually, however, the natural enemies of the louse seriously reduce its numbers by the time the Vine ceases its growth in the fall, and the few remaining lice, finding no more succulent and suitable leaves, seek the roots. Thus, by the end of September, the galls are mostly deserted, and those which are left are almost always infested with mildew (*Botrytis viticola*), and eventually turn brown and then decay. On the roots, the young lice attach themselves singly or in little groups, and thus hibernate. The male gall-louse has never been seen, and there is every reason to believe that he has no existence. Nor does the female ever acquire wings. Indeed, I cannot lay too much stress on the fact that *gallicola* occurs only as an agamic and apterous female form. It is but a transient summer

state, not at all essential to the perpetuation of the species, and does, compared with the other type, but trifling damage. I have found it occasionally on all species of the Grape Vine (*vinifera*, *riparia*, *æstivalis*, and *Labrusca*) cultivated in the Eastern and Middle States, and on the wild *Cordifolia*; but it flourishes only on the River-bank Grape (*riparia*), and more especially on the Clinton and Taylor, with their close allies. Thus, while legions of the root-inhabiting type (*radicicola*) are overrunning and devastating the Vineyards of France, this *gallicola* is almost unknown there, except on such American varieties as it infests with us. A few of its galls have been found at Sorgues, on a variety called Tinto; and others have been noticed on

Fig. 3. Type *Gallicola*:—*a*, *b*, newly-hatched larva, ventral and dorsal view; *c*, egg; *d*, section of gall; *e*, swelling of tendril; *f*, *g*, *h*, mother gall-louse—lateral, dorsal, and ventral views; *i*, her antenna; *j*, her two-jointed tarsus. Natural sizes indicated at sides.

vinifera Vines interlocking infested American Vines, or have been produced by purposed contact with the young *gallicola*. Similarly, there are many varieties, especially of *Labrusca*, which, in this country, suffer in the roots, and never show a gall on the leaves. The precise conditions which determine the production and multiplication of *gallicola* cannot now, if they ever can, be stated; but it is quite evident that the nature and constitution of the Vine are important elements, since such Vines as the Herbmont often bear witness, by their leaves covered with abortive galls, to the futile efforts the lice sometimes persist in making to build in uncongenial places. Yet other elements come into play, and nothing strikes the observer

Fig. 4. Type *Radicicola*:—*a*, roots of Clinton Vine, showing relation of swellings to leaf-galls, and power of resisting decomposition; *b*, larva as it appears when hibernating; *c*, *d*, antenna and leg of same; *e*, *f*, *g*, forms of more mature lice; *h*, granulations of skin; *i*, tubercles; *j*, transverse folds at border of joints; *k*, simple eyes.

as more curious and puzzling than the transitory nature of these galls, and the manner in which they are found—now on one variety, now on another. I was formerly inclined to believe that *gallicola* was a necessary phase in the annual cycle of the insect's mutations: in other words, that it was essential to the continuance of the species, and was probably the product of the egg laid by the winged and impregnated female. On this hypothesis I imagined that *gallicola* was probably the invariable precursor of *radicicola* in an uninfested Vineyard, and that, if galls were not allowed to develop in such a Vineyard, it would not suffer from root-lice. More extensive

experience has satisfied me that the hypothesis is essentially erroneous, and that, while the first galls may sometimes be produced by lice hatched from the few eggs deposited above-ground by the winged female, they are more often formed by young lice hatched on the roots, which, wandering away from their earthy recesses, are fortunate enough to find suitable leaf conditions. It is barely possible that under certain circumstances, as, for instance, on our wild Vines, where the soil around the roots is hard and compact, *gallicola* may become more persistent, and pass through all the phases belonging to the species without descending to the roots—the eggs wintering on the ground, or the young under the loose bark, or upon the canes. For a somewhat similar state of things actually takes place with another plant-louse (*Eriosoma pyri*), which in the Western United States normally inhabits the roots of our Apple trees, and only exceptionally the branches; while in the moister Atlantic States, and in England and moister parts of Europe, where it was introduced from this country, it normally infests the branches, and more exceptionally the roots. But there are no facts yet known to prove such to be the case with the Grape *Phylloxera*, even on our wild Vines, and I do not believe that it ever is the case in our cultivated Vineyards. As already indicated, the autumnal individuals of *gallicola* descend to the roots, and there hibernate. There is every reason to believe also that, throughout the summer, some of the young lice hatched in the galls are passing on to the roots; as, considering their size, they are great travellers, and show a strong predisposition to drop, their natural lightness, as in the case of the young cicada, and of other insects which hatch above but live under ground, enabling them thus to reach the earth with ease and safety. At all events, I know, from experiment, that the young *gallicola*, if confined to Vines on which they do not normally, and perhaps cannot, form galls, will, in the middle of summer, make themselves perfectly at home on the roots.

The *Radicicola* or Root-inhabiting Type.

We have seen that, in all probability, *gallicola* exists only in the apterous, shagreened, non-tubercled, fecund female form. *Radicicola*, however, presents itself in two principal forms. The newly-hatched larvæ of this type are undistinguishable, in all essential characters, from those hatched in the galls; but in due time they shed the smooth larval skin and acquire raised warts or tubercles which at once distinguish them from *gallicola*. In the development from this point the two forms are separable with sufficient ease; one (*a*) of a more dingy greenish-yellow, with more swollen fore-body, and more tapering abdomen; the other (*B*) of a brighter yellow, with the lateral outline more perfectly oval, and with the abdomen more truncated at tip. The first or mother form (fig. 4, *f*, *g*,) is the analogue of *gallicola*, as it never acquires wings, and is occupied, from adolescence till death, with the laying of eggs, which are less numerous and somewhat larger than those found in the galls. I have counted in the spring as many as 265 eggs in a cluster, and all evidently from one mother, who was yet very plump and still occupied in laying. As a rule, however, they are less numerous. With pregnancy this form becomes quite tumid and more or less pyriform, and is content to remain with scarcely any motion in the more secluded parts of the roots, such as the creases, satures, and depressions, which the knots afford. The skin is distinctly shagreened (fig. 4, *h*), as in *gallicola*. The warts, though usually quite visible with a good lens, are at other times more or less obsolete, especially on the abdomen. The eyes, which were quite perfect in the larva, become more simple with each moult, until they consist, as in *gallicola*, of but triple eyelets (fig. 4, *k*), and, in the general structure, this form becomes more degraded with maturity, wherein it shows the affinity of the species to the Coccidæ, the females of which, as they mature, generally lose all trace of the members they possessed when born. The second or more oval form (fig. 4, *e*) is destined to become winged. Its tubercles, when once acquired, are always conspicuous; it is more active than the other, and its eyes increase rather than diminish in complexity with age. From the time it is one-third grown, the little dusky wing-pads may be discovered, though less conspicuous than in the pupa state, which is soon after assumed. The pupæ (fig. 5, *e*, *f*) are still more active, and, after feeding a short time, they make their way to the light of day, crawl over the ground and over the Vines, and finally shed their last skin and assume the winged state. In this last moult the tubercled skin splits on the back, and is soon worked off, the body in the winged insect having neither tubercles nor granulations. In the great majority of insects the wings in the pupa are simply compressed and thickened without being folded, and in the imago they expand without material change in form. Those of our *Phylloxera* are rolled up both from the sides and the end, and, in expanding, they unroll in the manner designated at figure 6, *d*, *e*, *f*—the whole operation requiring but about five minutes. At first, and for some time after the moult, the

colour of the body of the new-fledged Phylloxera is of a uniform bright deep yellow, with the wings white and rather opaque, and the eyes brown. The dark thoracic band and more diaphanous and smoky nature of the wings are gradually acquired in the course of a day, and the insect finally presents the appearance of figure 5, *g*, *h*. The wings, when highly magnified, are seen to be thickly covered with minute hooks (fig. 7, *f*). These winged insects are most abundant in August and September, but may be found as early as the 1st of July, and until the Vines cease growing in the fall. The majority of them are females, with the abdomen large, and more or less elongate. The veins of the front wing are not connected (fig. 6, *a*), and, by virtue of the large abdomen, the body appears somewhat constricted behind the thorax. From two to five eggs may invariably be found in the abdomen of these, and are easily seen when the insect is held between the light, or mounted in balsam or glycerine. A certain proportion have an entirely different shaped and smaller body, the abdomen being short, contracted, and terminating in a fleshy and dusky protuberance; the limbs stouter, and the wings proportionately larger and stouter, with their veins connecting (fig. 6, *b*). I have never found perfect eggs in the abdomen of this shorter form, but, instead, several vesicles (fig. 7, *e*) containing granulations in sacs; and this form has been looked upon as a probable male by myself and others in the past. But in the light of present knowledge it must be looked upon as merely an abnormal female, and the vesicles as immature eggs. Balbiani made the curious discovery, in the annual development of Phylloxera quercus, that the winged individuals, which appear in August, fly off to new leaves and deposit their unimpregnated eggs, to the number of five to eight. These eggs are of two different sizes, the smaller being readily separated from the larger. They hatch in about a dozen days, the smaller giving birth to males, and the larger to females, which have neither mouth-parts nor digestive organs, and neither grow nor moult after birth. The sole aim of their existence is the reproduction of the species, and they crawl actively about and gather in little multitudes in the crevices and interstices which are afforded them. Four or five days after birth the female lays a solitary egg, which, increasing somewhat after impregnation, had caused her abdomen to swell and enlarge a little prior to oviposition. Two or three days after this operation the mother dies; but the male lives as long again. This solitary egg, which Balbiani calls the winter egg, soon takes on a dark colour, which indicates its fecundity and distinguishes it from parthenogenetic eggs of both the winged and wingless females. It is surmised that this egg passes the winter to give birth in spring to the form destined to recommence the cycle of development belonging to the species. These discoveries are truly remarkable, and appear to me all the more so since Balbiani likewise found that the individuals which never become winged attain maturity without laying eggs on the leaves on which they were born, but crawl on to the branches and in the interstices of the old scales at the base of the new year's growth. There they lay a

number of eggs, which are absolutely like those deposited by the winged females, and, like them, produce the sexual individuals, *i.e.*, both males and females. M. Maxime Cornu has already announced having found a sexual individual, without mouth-parts, of the Grape Phylloxera; and it is quite likely, now that Balbiani has paved the way, that we shall this year have its natural history complete. But whether the Grape Phylloxera produces this fecundated and solitary egg or not, such an egg is neither essential to its winter life, nor to that of an American species (Phylloxera Rileyi), which will be described further on, and which is, in every respect, very closely allied to the European quercus. The Grape Phylloxera has been found to agree precisely with its Oak congener in the sexual character of the progeny from the winged females; and, indeed, these sexed individuals have now been traced in the Oak and Grape species (quercus and vastatrix) in Europe, in three species (Rileyi, vastatrix and what is probably caryæcaulis) in America. Balbiani has also proved the analogy between the two species to be still more perfect, in that

many of the underground wingless females also, towards the end of autumn, lay eggs of two sizes, which give birth to the true mouthless and wingless males and females, undistinguishable in structure and function from the progeny of the winged females. We thus have the spectacle of an underground insect possessing the power of continued existence even when confined to its subterranean retreats. As fall advances the winged individuals become more and more scarce; and, as winter sets in, only eggs, newly-hatched larvæ, and a few apterous egg-bearing mothers are seen. These last die and disappear during the winter, which is mostly passed in the larva state, with here and there a few eggs. The larvæ thus hibernating (fig. 4, *b*), become dingy, with the body and limbs more shagreened and the claws and digituli less perfect than when first hatched; and, of thousands examined, all bear the same appearance, and all are furnished with strong suckers. As soon as the ground thaws and the sap starts in the spring, these young lice work off their winter coat, and, growing apace, commence to deposit eggs. I have examined thousands in the Vineyard in early spring, and other thousands reared artificially in a warm room in

Fig. 5. Type Radicicola:—*a*, shows a healthy root; *b*, one on which the lice are working, representing the knots and swellings caused by their punctures; *c*, a root that has been deserted by them, and where the rootlets have commenced to decay; *d*, *d*, *d*, show how the lice are found on the larger roots; *e*, female pupa, dorsal view; *f*, same, ventral view; *g*, winged female, dorsal view; *h*, same, ventral view; *i*, magnified antenna of winged insect; *j*, side view of the wingless female, laying eggs on roots; *k*, shows how the punctures of the lice cause the larger roots to rot.

winter, and all, without exception, assumed the degraded form (*a*) already described. At this season of the year, with the exuberant juices of the plant, the swellings on the roots are large and succulent, and the lice plump to repletion. One generation of the mother form follows another—fertility increasing with the increasing heat and luxuriance of summer—until at least the third or fourth has been reached before the winged form makes its appearance in the latter part of June or early in July. Such are the main features which the development of the insect presents to one who has studied it in the field as well as in the closet. This polymorphism, which at first strikes us as singular, is quite common among plant lice, and many curious instances of still more striking character might be given. Even the differences themselves between gallicola and radicola are

winter, and all, without exception, assumed the degraded form (*a*) already described. At this season of the year, with the exuberant juices of the plant, the swellings on the roots are large and succulent, and the lice plump to repletion. One generation of the mother form follows another—fertility increasing with the increasing heat and luxuriance of summer—until at least the third or fourth has been reached before the winged form makes its appearance in the latter part of June or early in July. Such are the main features which the development of the insect presents to one who has studied it in the field as well as in the closet. This polymorphism, which at first strikes us as singular, is quite common among plant lice, and many curious instances of still more striking character might be given. Even the differences themselves between gallicola and radicola are

more apparent than real. Individuals of the latter are often met with, which, in the comparative obsolescence of their tubercles, are almost undistinguishable from the former; and the tubercles, like many other purely dermal appurtenances, are of an evanescent and unimportant character. Many insect larvæ, which are normally granulated with papillæ, not unfrequently have these more or less obsolete, and at some stages of growth have the skin absolutely smooth. The same thing holds true of tubercles, which, as in the case of the Imported Currant worm (*Nematus ventricosus*), are often completely cast off at a moult. In *Phylloxera* they are often very variable in size, as we shall see in Rileyi; and in quercus, according to several trustworthy authors, the tubercles which are characteristic of the species in Southern France are entirely wanting round Paris. If we carefully study them in vastatrix, we shall find that they consist of points where the granulated skin is gathered round a fleshy

Fig. 6. Pterogostic Characters:—*a*, *b*, different venation of front wing; *c*, hind wing; *d*, *e*, *f*, showing development of wings.

hair in little rugosities, and becomes darker (fig. 4, *i*). They do not occur in the newly-hatched larva, are not visible immediately after each moult, and are lost again in the winged individuals. In the form gallicola we shall find, upon careful examination, especially of the exuvia, that, as Max. Cornu has shown, there are rows of short hairs, extending beyond the natural granulations, and corresponding to those on the tubercles of radicolola. These hairs are more visible on the younger and smoother lice after the first moult; and they are sometimes so stout, particularly on the abdomen, as to remind one of those on Rileyi, to be described. The ventral characteristics of the two types are identical. Since I proved, in 1870, the absolute identity of these two types by showing that the gall lice become root lice, the fact has been repeatedly substantiated by different

Fig. 7. Type Radicolola:—*a*, *b*, pupa and imago of a short-bodied form, once supposed to be the male; *c*, *d*, its antenna and leg; *e*, vesicles found in abdomen.

observers. Yet, strange to say, no one has heretofore succeeded in making gall lice of the young hatched on the roots, though I formerly supposed that Signoret had done so. It is, therefore, with much satisfaction that I record the fact of having succeeded this winter in obtaining galls on a young Clinton Vine from young radicolola, and of thus establishing, beyond question, the specific interrelation and identity of the two types. I make this announcement with all the more pleasure, that for three years past, both on Vines growing out-doors and in pots indoors, I had in vain attempted to obtain the same result.

External Effects of the Disease.

The result which follows the puncture of the root-louse is an abnormal swelling, differing in form according to the particular part and texture of the root. These swellings, which are generally

commenced at the tips of the rootlets, where there is excess of plasmatic and albuminous matter, eventually rot, and the lice forsake them and betake themselves to fresh ones—the living tissue being necessary to the existence of this as of all plant-lice. The decay affects the parts adjacent to the swellings, and on the more fibrous cuts off the supply of sap to all parts beyond. As these last decompose, the lice congregate on the larger ones, until at last the root system literally wastes away. During the first year of attack there are scarcely any outward manifestations of disease, though the fibrous roots, if examined, will be found covered with nodosities, particularly in the latter part of the growing season. The disease is then in its incipient stage. The second year all these fibrous roots vanish, and the lice not only prevent the formation of new ones, but, as just stated, settle on the larger roots, which they injure by causing hypertrophy of the parts punctured, which also eventually become disorganised and rot. At this stage the outward symptoms of the disease first become manifest, in a sickly yellowish appearance of the leaf and a reduced growth of cane. As the roots continue to decay, these symptoms become more acute, until by about the third year the Vine dies. Such is the course of the malady on Vines of the species vinifera, when circumstances are favourable to the increase of the pest. When the Vine is about to die it is generally impossible to discover the cause of the death, the lice, which had been so numerous the first and second years of invasion, having left for fresh pasturage.

Mode of Spreading.

The gall-lice can only spread by travelling, when newly hatched, from one Vine to another; and if this slow mode of progression were the only one which the species is capable of, the disease would be comparatively harmless. The root-lice, however, not only travel under-ground along the interlocking roots of adjacent Vines, but crawl actively over the surface of the ground, or wing their way from Vine to Vine, and from Vineyard to Vineyard. Doubts have been repeatedly expressed by European writers as to the powers of such a delicate and frail-winged fly to traverse the air to any great distance. On a calm, clear day, the latter part of last June, it was my fortune to witness a closely allied species (*Phylloxera caryæfoliæ*), of the same size and proportions, swarming on the wing to such an extent that to look against the sun revealed them as a myriad silver specula. They settled on my clothing by dozens, and any substance in the vicinity that was the least sticky was covered with them. With such a sight before one's eyes, and with full knowledge of the prolificacy of these lice, it required no effort to understand the fearful rapidity with which the *Phylloxera* disease has spread in France, or the epidemic nature it has assumed. Imagine such swarms, mostly composed of egg-bearing females, slowly drifting, or more rapidly blown, from Vineyard to Vineyard; imagine them settling upon the Vines, and depositing their eggs, which give birth to fecund females, whose progeny in five generations, and probably in a single season, may be numbered by billions, and you have a plague (should there be no conditions to prevent that increase) which, though almost invisible and easily unnoticed, may become as blasting as the plagues of Egypt. As early as 1871 I showed with what facility and power the species referred to in the above extract can take wing when the atmospheric conditions are favourable; and on the 27th of last September, the weather being quite warm and summer-like, with much moisture in the atmosphere, I witnessed the same power of flight in the Grape *Phylloxera*. Some two hundred winged individuals, which I had confined, became very active and restless, vigorously vibrating their wings and beating about their glass cages. Upon opening the cages, the lice began to dart away and were out of sight in a twinkling. They have been caught in spider-webs in Europe, and I have repeatedly captured them on sheets of paper prepared with bird-lime and suspended in an infested Vineyard; and am satisfied that they can sustain flight for a considerable time under favourable conditions, and, with the assistance of the wind, they may be wafted to great distances. These winged females are much more numerous in the fall of the year than has been supposed by entomologists. Wherever they settle, the few eggs which each carries are sufficient to perpetuate the species, and thus spread the disease, which, in the fullest sense, may be called contagious. Whether in a state of Nature these winged females show a preference for any one part of the Vine in the consignment of their eggs is not yet known. It is quite certain, however, that they do not re-enter the ground, though they may, and probably do, often push their eggs into the minute cracks and crevices in the surface of the ground. In confinement I have had such eggs deposited both on the leaves and on the buds, and from the preference which, in ovipositing, these aerial mothers showed for little balls of cotton placed in the corners of their cages, I infer that the more tomentose portions of the Vine, such as the bud, or the base of a leaf-stem, furnish a desirable *nidi*. On this hypothesis it is quite possible for the insect to be introduced from Vine-

yard to Vineyard, or from country to country, as well upon cuttings as upon roots. The sexual individuals, already referred to, from the unimpregnated winged females, hatch in ten or twelve days after the laying of the eggs, under favourable conditions of temperature and moisture. It is possible, however, that the later deposited eggs remain unhatched throughout the winter. Yet where I have supplied these winged mothers with earth, they have repeatedly left their eggs in the cracks of the surface, especially between the earth and the walls of whatever vessel they were confined in; and as they have an inveterate habit of elongating the abdomen and turning the tip from side to side as if feeling for some fissure; and as the eggs require moisture, and hatch most readily within such crevices of moist earth, the soil is perhaps the natural means, especially around the base of the Vine.

Susceptibility of Different Vines to the Disease.

As a means of coping with the Phylloxera disease, a knowledge of the relative susceptibility of different varieties to the attacks and injuries of the insect is of paramount importance. As is so frequently the case with injurious insects, and we have a notable instance in the common Currant Aphis (*Aphis Ribesii*), which badly affects the leaves of some of the Currants, but never touches the Gooseberry which belongs to the same genus, the Phylloxera shows a preference for, and thrives best on, certain species, and even discriminates between varieties; or, what amounts to the same thing practically, some varieties resist its attacks, and enjoy a relative immunity from its injuries. It would, I fear, be useless, and certainly unnecessary here, to attempt to ascertain the reason why certain Vines thus enjoy exemption, while others so readily succumb; but in a broad way it may be stated that there is a relation between the susceptibility of the Vine and the character of its roots—the slow-growing, more tender-wooded, and, consequently, more tender-rooted varieties succumbing most readily; the more vigorous growers resisting best.

Prevention of the Disease.

It occurred to me that by grafting the more susceptible on the roots of the more resistant varieties, we might, in a great measure, counteract the disease, even if all other remedies failed. In the Grape-growing districts of France, where the disease is so sweeping, and where the Grape is so exclusively grown that it affects whole communities, the people may be obliged, and can afford to go to much labour and expense in the use of insecticides to save their Vines. Such insecticides may also be used in this country, where it is desired to save a few choice Vines regardless of expense and time. But I greatly fear that no direct remedy for such an underground enemy will ever be discovered that will not entail too much labour and expense to be used, to any great extent, by our own Grape growers, who will either prefer to confine their attention to varieties which resist, or abandon the business entirely. Yet if it shall once be demonstrated that varieties which now fail may be grown when grafted on those which resist, I see no reason why it should not become as much a custom and a maxim among Grape-growers, to use some other Vine as stock for such varieties, as it already is among Pear growers to use the Quince, or among Cherry growers to use Mahaleb, Mazard, or Morello, as stocks. In the course of a year or two we shall be able to fairly judge of the efficacy of the plan, for, aside from the trials that I am making in this country, others are being made on an extensive scale in France. Quite a number of plants, for the purpose of experiment, were sent over there from this country in the spring of 1872; and the demand has now become so great that a single firm, Isidor, Bush & Co., of St. Louis, has lately received orders for about four hundred thousand cuttings to be consigned to one place, Montpellier, and consisting of such varieties as have been recommended by Prof. Plançon and myself as best resisting the disease. There is every reason to hope for the best results from these importations, as the Vines which best resist here, and which were planted there in 1871 and 1872, in Phylloxera-infested districts, have, thus far, done surprisingly well, as MM. J. Leenhardt-Pomier, V. Pulliat, and others, testify.

Other Preventive Measures.

In planting a new Vineyard, the greatest care should be taken not to introduce the Phylloxera on the young plants, and a bath of weak lye or strong soap-suds before planting will, perhaps, prove the best safeguard. Remembering that the lice are spreading over the ground from July till fall, and principally in the months of August and September, a thorough sprinkling of the surface with lime, ashes, sulphur, salt, or other substance destructive to insect life, will, no doubt, have a beneficial effect in reducing their numbers and preventing their spread. The insect has been found to thrive less, and to be, therefore, less injurious in a sandy soil; while a mixture of soot with the soil has had a beneficial effect in destroy-

ing the pest. I have therefore recommended for the more susceptible varieties that they be planted in trenches first prepared with a mixture of sand and soot. An addition of lime will also prove beneficial. There is every reason to believe that Vines are rendered less susceptible to the disease by a system of pruning and training that will produce long canes and give them as nearly as possible their natural growth.

Natural Enemies.

There are a number of different predaceous insects which serve to keep the leaf-lice in check; but, as the injury is mostly done underground, it will suffice to enumerate the principal of these in this connection. The most efficient is a black species of Fringe-

Fig. 8. Thrips.

wing, or Thrips with white wings (*Thrips phylloxerae*). The egg, which is thrice as large as that of the louse, ellipsoidal, and with a faceted surface, is deposited within the gall among its legitimate inhabitants; and the young Thrips, which differ from their parents not only in lacking wings but in being of a blood-red colour, with only the extremities and the members black, play havoc with the lice. They are active supple creatures, and turn up menacingly the posterior part of the body when disturbed. They are found in several different kinds of Phylloxera galls, and do more than any other species to keep the leaf-inhabiting Grape

Fig. 9. Lace-wing Fly:—a, eggs; b, larva; c, cocoon; d, fly.

Phylloxera within bounds. The next most efficient aid in the destruction of the leaf-lice is found among the lace-wing flies, two species of which, more especially, viz.: the weeping lace-wing (*Chrysopa plorabunda*) and the consumptive lace-wing (*C. tabida*), I find very frequently within the galls devouring their contents. These flies are known by their brilliantly golden eyes and the offensive odour which some of them emit. The eggs are adroitly deposited (fig. 9, a) at the tip of long, silk-like stalks, in order to prevent the first-born larvae from exercising their cannibalistic propensities on their yet unborn brethren. The larva (fig. 9, b) is

Fig. 10. Lady Bird:—Larva, pupa, and beetle.

Fig. 11. Syrphus Larva.

Fig. 12. Syrphus Fly.

very rapacious, and, when ready to transform, winds itself up into a wonderfully small cocoon (considering the size of the insect which makes it, and which issues from it) which is spun from the extremity of the body and from which it issues, when about to acquire wings, through a neatly-cut, circular aperture. Next in order, as Phylloxera enemies, may be mentioned the lady birds (*Coccinella*), especially certain small, dark-brown species belonging to the genus *Scymnus*, and whose young, thickly covered with white and evenly-shorn tufts of a cottony secretion, are frequently found at their good work within the galls. Following

these may be mentioned, as auxiliaries, certain Syrphus-fly larvæ, which, being blind, go groping about among the eggs and young lice which they seize and suck to death. Also certain orange larvæ of a smaller two-winged fly (*Leucopis*); a few genuine bugs (*Heteroptera*), and notably the Insidious Flower-bug (*Anthocoris insidius*, fig. 13), and certain smaller Hymenopterous parasites. The enemies known to attack the Phylloxera under ground are, naturally enough, fewer in number. In one instance, I have found a *Scymnus* larva at the work six inches below the surface, and there is a Syrphus fly (*Pipiza radicum*, fig. 14), whose larva lives under ground and feeds both on the Apple tree root-lice, and on this Grape root-lice. Wonderful, indeed, is the instinct which teaches this blind larva to penetrate the soil in search of its prey; for the egg must necessarily be laid at the surface. But, though the under ground enemies of its own class are few, I have discovered a mite which preys extensively upon this root-inhabiting type, and which renders efficient aid in keeping it in check in this country. This mite (*Tyroglyphus phylloxerae*, fig. 15) belongs to the same genus as the cheese and meal mites (*T. siro*), and the species (*T. entomophagus*) which infests preserved insects and is such a pest in cabinets. As is the rule with mites, it is born with but six legs, but acquires eight after the first or second moults. It varies considerably in form, with age, and in studying it with a view of distinguishing it specifically from other described species, I have

Fig. 13. Insidious Flower Bug.

Fig. 14. Root-lice Syrphus Fly:—a, larva; b, pupa; c, fly.

noticed all the different tarsal characters shown as *d*, *f*, *g*, and *h* (fig. 15), and on which distinct genera have been founded. Mites present themselves in such different forms that the adolescent stages of the same species have been made to represent distinct families by authors who never studied the development of these beings. Thus the genera *Astoma*, *Leptus*, *Caris*, *Myobia*, &c., are now known to be but the larval forms, some of them commonly met with as such but not yet connected with the more perfect and more mature forms. The different species of *Tyroglyphus*, so far known, prey on vegetal and animal substances, particularly when these

Fig. 15. Phylloxera Mite:—a, dorsal; b, ventral view of female; c, mouth-parts; d, f, g, h, forms of tarsal appendages; e, ventral tubercles of male.

are in a decaying or putrescent condition. In one of their forms (*Hypopus*) they are also known to be externally parasitic on living animals. The species under consideration combines both habits, as when young it mostly contents itself with the altered sweets of the roots which rot from the punctures of Phylloxera, while, when older, it preys by preference on the lice themselves. A singular feature in the life-history of many of the species of the genus *Tyroglyphus* is the fact that under certain conditions an entirely different form, with a hard brown chitinous covering or shield, and characterised by Dugès as a new genus by the name of

Hypopus, develops within the softer body, and finally issues from it by splitting open the softer skin. Claparède, who believed this form to be the male, has carefully described and figured the process of change in the European *Hypopus Dujardini*, and that *Tyroglyphus phylloxerae* has its *Hypopus* form was independently proved by Prof. Planchon and myself—the letters announcing the observations on either side having crossed *en route*. *Hypopus*, as already stated, has been found preying upon living animals. *Tyroglyphus* is a slow traveller, and with its soft body cannot endure exposure to the air, or resist the attacks of other minute animals. Yet it is ubiquitous, living both above and below ground, and swarming on decomposing animal and vegetal substances. When these have once been consumed or reduced to dry powder, what becomes of the swarming mites? M. Maguin has, I think, rightly answered the question. All adult and old mites, together with the young hexapod larvæ, perish; but those in the adolescent stage, the octopod pupæ, are preserved by their power of putting on a coat of mail which protects them against external influences until they can attach themselves to some living and moving animal (flies, beetles, spiders, millipeds, and larger animals), which become their carriers and transport them to places

Fig. 16. *Hoplophora arctata*:—a, b, c, d, e, different attitudes assumed by it; f, strongly magnified leg.

which they could otherwise never reach, and where, finding appropriate food, they throw off the disguise and breed as *Tyroglyphs*, with their well-known fecundity. Associated with this predaceous mite, I have found another (*Hoplophora arctata*, Fig. 16), of very curious form, reminding one strongly of a mussel; and I refer to it in this connection because I once strongly suspected it likewise to be, in some way, related to the soft-bodied *Tyroglyphs*. In studying these mites and their habits, I had frequently filled vessels with Grape roots from which all but *Tyroglyphs* and *Phylloxerae* had, to all appearance, been carefully excluded; only to find, on subsequent examination, a number of these mussel-like *Hoplophoras* and a corresponding decrease in the number of *Tyroglyphs*. This happened more especially in the fall of the year, and I could not help suspecting that the former might prove to be a winter or hibernating form of the latter. There is so much yet to learn of the polymorphism of mites that the suspicion may yet prove justifiable. But with our present knowledge it is safest to explain the facts above stated on the ground that the *Hoplophoras* were at first buried, and consequently invisible, within the roots examined, and that the decrease in the number of *Tyroglyphs* was owing to death and other causes—an explanation which is all the more plausible from the fact that I subsequently found the same narrow-bodied *Hoplophora* swarming in decaying Cotton-wood logs. *Hoplophora* (meaning armed or weapon-carrier) is an anomalous genus belonging to a curious family of mites (*Oribatidæ*), distinguished, as Nicolet well sets forth, from all other families by having a hard covering which is analogous to that of many hexapods, but less elastic or yielding, so that, while resisting a great degree of pressure, when it once gives way, it cracks and fractures with the brittleness of glass. These coverings are differently formed and sculptured, and frequently ornamented with protecting spines. The mites of this family are also distinguished from other mites by their organs of respiration which are at the superior base of the cephalothorax, and look like eyes, being rounded elevations surmounted by a hair. The family comprises two great divisions:—First, those which in the larva state have a form and appearance widely different from those of the adult, which are assumed only at the last moult. Second, those which are born more in the image of the adult form, to which they gradually approach by each successive moult. The genus *Hoplophora*, according to Nicolet, is further anomalous by being born with eight legs, whereas all other mites, even those of its own family, are born with but six; Claparède, however, shows that at least one species (*H. contractilis*) is hexapod before the first moult. Another peculiarity belonging to it is the mobility of the cephalothoracic shield, which closes over the abdomen and fits tight like the lid of a box, whenever the animal withdraws its head and limbs, which it does on the slightest disturbance. Indeed, the hardened body-covering is admirably constructed for the purpose of protection. The species under consideration differs from all others described in the form of the horny covering, which is so narrow that the animal

topples over on its side the moment the limbs are withdrawn. Since the discovery of this Phylloxera-feeding Tyroglyph in America, numerous sensational and exaggerated newspaper articles have appeared, glowingly describing how the French Vineyards are to be saved from the ravages of the Phylloxera by the introduction of this its enemy; and I have received several orders from Europe for supplies of the cannibal. Professor Planchon, it is true, will attempt to introduce it, and we hope with success; but, from what is here said, it is evident that the enthusiasts who expect so much are doomed to disappointment.

Direct Remedies.

The leaf-lice, which do not play such an important part in the disease as was at first supposed, may be controlled with sufficient ease by a little care in destroying the first galls which appear, and in pruning and destroying the terminal growth of infested Vines later in the season. The root-lice are not so easily reached. As the effort will be according to the exigency, we may very naturally look to France for a direct remedy, if one be ever discovered; but of all the innumerable plans, patented or non-patented, that have been proposed—of all the many substances that have been experimented with under the stimulus of a large national reward, no remedy has yet been discovered which gives entire satisfaction, or is applicable to all conditions of soil. Nor is it likely that such a remedy ever will be discovered. A large majority of the remedies proposed, such as the planting of *Madia sativa* among the Vines to catch the insect by its viscous property, or inoculating the Vines with the essence of *Eucalyptus globulus*, are, upon their face, unworthy of practical consideration, or absurd. These we will pass by, and briefly mention only those which have been more or less productive of good. Submersion, where practicable, and where it is total and sufficiently prolonged, is a perfect remedy. This is what even the closest student might expect, as he finds that excessive moisture is very disastrous to the lice. M. Louis Faucon, of Graveson (Bouche du Rhône), France, has abundantly proved its efficacy, and has, by means of it, totally annihilated the insect in his Vineyard, which was suffering from it four years ago. From his experience we may draw the following conclusions:—1. The best season to submerge is in autumn (September and October), when the lice are yet active and the Vines have ceased growing. Submergence for twenty-five to thirty days, at this season, will generally rout the lice. 2. A submergence of forty to fifty days, in winter, is required, and even where the water is allowed to remain during the whole of this season, the Vineyard does not suffer. [I should consider this very doubtful.] 3. A Vineyard should never be inundated for a longer period than two days in summer, or during growth; and though these brief inundations at that season, affect only the few lice near the surface, and are by no means essential, they are nevertheless important auxiliaries to the more thorough fall or winter submersion, as they destroy the few lice which are always invading a Vineyard in infested districts. These summer inundations will be necessary only after the winged insects begin to appear; and three or four, each lasting less than two days, made between the middle of July and the fall of the leaf, will effect the end desired. 4. An embankment should be made around the Vineyard in order that the water may evaporate and permeate the earth, but not run on and carry away any nutritive properties of the soil. The varied success which has attended the different attempts to rout the enemy by inundation, is owing to the lack of thoroughness in many of them. The ground must be thoroughly soaked for a sufficient length of time. Temporary irrigation does not accomplish the end, for the reason that it does not reach all the lice, and does not break up the numerous air bubbles which form in the soil and prevent the drowning of many of the insects. On our best hilly Vine land, thorough submersion is impracticable; but, on our bottom lands some of the Grapes which fail now may be made to succeed by its means. Of 140 different applications made by an intelligent and competent commission in the department of Hérault, France, most of the pure insecticides proved valueless. Many of them, such as carbolic acid, oil of cade, arsenious acid, sulphide of calcium, sulphide of mercury, arsenate of potash, &c., will effectually kill the insect when brought in direct contact with it; but in field practice they can either not be brought in this direct contact, or else cannot be used strong enough to kill all the lice without injuriously affecting the Vine. Carbolic acid, added to water at the rate of about one per cent., applied by pouring into deep holes made by a crow-bar or auger, has given satisfactory results; and a thorough application of soot has also been strongly advocated by those who have tried it. In the experiments that I have been able to make in a small way, a thorough mixing with the soil of a cheap carbolic powder, has given good results. The latest insecticide that has attracted attention and given great hopes in France, is the bi-sulphide of carbon. It seems to have been used as early as 1869 by Baron

Thénard, but was brought prominently before the public last autumn by Messrs. Monestier, Lautand and d'Ortoman, who first proposed to introduce it at a great depth in the soil, so as to utilise its vapour. A vapour will naturally have the advantage over a liquid, as it will more effectually permeate the soil and reach the lice. The simplest method of applying the sulphuret or bi-sulphide, is by making three holes, two or three feet deep, around the foot of the Vine, then quickly pouring in the liquid and plugging them up. The holes may be made by a pointed bar driven by a maul. About two ounces of the liquid to each of these three holes are recommended. Soon after the announcement of this method, I employed it as a test on three Vines which I knew to be infested with Phylloxera, using 3 ounces to the first, 6 ounces to the second, and 9 ounces to the third—the soil being a light clayey loam. At the end of twelve days I found plenty of living lice on the first and second Vines, and such were found long afterwards, though in small numbers up to the time of the freezing of the ground. On the third Vine all the lice were evidently charred, but the Vine was also evidently injured, as the leaves wilted as though they had been scorched, though whether from the vapour issuing from the ground or from the injury to the root, it was impossible to determine. I think, however, from the former, as the larger roots were yet alive late in the season, and the Vine seems at this writing to be living. After very careful and laborious experiments made in France at different points and on different kinds of soil, by a commission especially charged with studying the action of this chemical, under the method proposed by Messrs. Monestier, Lautand, and d'Ortoman, it fails to fulfil the sanguine expectations of these gentlemen. The liquid is costly, its application is laborious, and there is great difficulty in reaching and killing all the lice without injuring the Vine. Great caution must also be had in its use, as it is extremely volatile and explosive—the vapour igniting at a great distance from the vessel containing it. While, therefore, not very satisfactory results have followed the use of pure insecticides, the application of fertilisers intended to invigorate the Vine and at the same time injure the lice, has been more productive of good. Especially has this been the case with fertilisers rich in potassic salts and nitrogenous compounds, such as urine. Sulphuret of potassium dissolved in liquid manure; alkaline-sulphates, with copperas and Rape seed; potassic salts, with guano; soot and cinders, are, among other applications, most favourably mentioned.

Why the Insect is more Injurious in Europe than America.

Without going into particulars, several good reasons may be given to explain the fact that Phylloxera is more devastating in the Vineyards of France than in our own. There exists a certain harmony between the indigenous fauna and flora of a country, and our native Vines are such as, from their inherent peculiarities, have best withstood the attacks of the insect. The European Vine, on the contrary, succumbs more readily, not only because of its more tender and delicate nature, but because it has not been accustomed to the disease; there being, doubtless, a parallel between this case and the well-known fact that diseases which are comparatively harmless among peoples long accustomed to them, become virulent and often fatal when first introduced among those that have been hitherto uncontaminated. Then the particular natural enemies of the insect which belong to its own class, and which in this country help to keep it within due bounds, are lacking in Europe; and it will require some time before the closely allied European predaceous species will prey upon and check it there to the same extent. The Phylloxera will, also, all other things being equal, have an advantage in those countries where the mildness and shortness of the winter allow an increase in the annual number of its generations. Finally, the differences in soils and in modes of culture have no insignificant bearing on the question in hand. Though Phylloxera, in both types, is found on our wild Vines, it is very doubtful if such wild Vines in a state of Nature are ever killed by it. With their far-reaching arms embracing shrub and tree, their climbing habit unchecked by the pruner's knife, these Vines have a corresponding length and depth of root, which render them less susceptible to injury from an underground enemy. Our own method of growing them on trellis approaches more nearly these natural conditions than that employed in the ravaged French districts, where the Vines are grown in greater proximity and allowed to trail on the ground, or are supported to a single stake. Their soil is also, as a rule, poorer than ours. One other important fact must also be taken into account in this connection, as it throws new light on the rapid spread of the disease in France. We have seen that from the middle of July to the end of the growing season the winged females are issuing from the ground, and scattering far and near to other localities. When we reflect that a single quart bottle, filled with roots taken from an infested Vine in August will furnish daily, for two or three weeks,

upward of a dozen such winged females, we gain some idea of the immense numbers supplied in the course of the year by a single acre of infested Vines. Last August M. J. Lichtenstein announced the discovery that these winged females congregated on a species of Scrub Oak (*Quercus coccifera*) for the deposition of their eggs, and while, as I predicted at the time, the insects he discovered proved to belong, for the most part, to Oak-feeding species of *Phylloxera*; yet, as he assures me, he is still convinced that he also found a certain proportion of the Grape species upon such Oaks. This I can the more readily believe because I have myself beaten from our Post Oak a large species which cannot possibly live on Oak, but which forms a gall on Hickory. The winged female *Phylloxera* is, therefore (and I know such to be true, in a measure of *Pemphigus* and *Eriosoma*) not drawn by instinct to any particular plant, but is wafted about, and will lay her eggs, or, in other words, deliver herself of her progeny, wherever she happens to settle. If this be upon the Grape Vine, well and good—the young live and propagate; if upon other plants, they perish. We thus have the spectacle of a species annually wasting itself to a greater or less extent, just as in the vegetable kingdom most species produce a superabundance of seed, the larger proportion of which is destined to perish. Thus, in the thickly-planted Vine districts of France, few winged insects would fail to settle where their issue could survive; while, in America, an immense number annually perish in the large tracts of other vegetables intervening between our Vineyards.

The American Oak *Phylloxera* (*P. Rileyi*).

There are several described and undescribed species of *Phylloxera* in this country, most of them inhabiting leaf-galls made on our different Hickories. The species herewith figured is the only external feeder known in America, and is briefly alluded to in this connection showing that, as with the Grape *Phylloxera*, it does not need a "winter egg" to enable it to hibernate, but passes the winter in the larva state (as at fig. 18), firmly attached to the tender bark of the younger twigs, and thus braving all the vicissitudes and inclemencies of that season. In the summer it is found on the under surface of the leaves of the White and Post Oaks, in the wingless female state of all sizes. Soon after it is born it inserts its beak into the leaf-tissue, and becomes more or less stationary. It causes no swelling of the leaf, but a yellow circular spot (fig. 17, *d*) somewhat larger than its own body and showing most plainly on the upper surface. The eggs are laid singly round the louse, and the process of parthenogenetic reproduction goes on for several generations, as in the Grape *Phylloxera*. By about the end of August, when these lice and their eggs are often very numerous, and when the speckled and often withered appearance of the leaf easily betrays their presence, the winged individuals begin to appear. This species is at once distinguished from all other American species, so far known, by its slender form and small size, but particularly by the long tubercles of the larger apterous individuals, and of the pupæ (fig. 17, *a*). Otherwise it greatly resembles the Grape *Phylloxera* in colour, and in the different forms it assumes. In habit and general appearance it very closely resembles the European Oak *Phylloxera*; but differs remarkably in its winter habit from what has hitherto been recorded of this last species, in that the last hatched larvæ in the fall fasten themselves to the more tender Oak twigs, where they rest till the following spring, with scarcely any change except in the deepening of the colour, which, as in the young Grape *Phylloxera*, hibernating on the roots of its food plant, becomes deeper and acquires a yellowish, or even a reddish-brown, tint. As the leaves begin to put forth, our young Oak *Phylloxera* cast off their winter skin, and their lethargy with it. They may then be seen crawling up and down the twigs, but do not settle on the leaves.

Fig. 17. *Phylloxera Rileyi*:—*a*, pupa; *b*, winged female; *c*, antenna greatly enlarged; *d*, portion of infested leaf, underside.

Fig. 18. *Phylloxera Rileyi*:—*a*, *b*, dorsal and ventral views of larva as seen hibernating; *c*, *d*, highly magnified leg and antenna of same.

Attaining, in a few days, full growth, they begin a virginal reproduction by covering the twigs with eggs, which hatch in about a week if the weather is warm and propitious. Thus the hibernating lice acquire their growth, and give birth to the first generation, in the short space intervening between the opening of the buds and the full growth of the first leaves. Beyond this I have not yet traced the vernal history of the species. Several parthenogenetic generations then follow each other until the winged females begin to appear early in July, when from them are born the sexual individuals, just as with the Grape Vine, and the European Oak species. With the drying of the leaf in fall the young lice congregate on the twigs, and the older ones perish.

GARDENING FOR THE WEEK.

Hardy Flowers, Alpine Plants, and the Wild Garden.

How to Plant an Herbaceous Border.—Having arranged (see p. 98) where the herbaceous border is to be, and how it is to be made, the next point is, how it is to be planted. Let us presume that the border is 8 or 10 feet wide, and that it will admit of four or five rows of plants. These individual rows must, of course, be graduated to some extent, according to height, though, in this respect, a considerable amount of variation will be advisable compared with the effective distribution of the contents of one of our regular floral ribbon borders; and I may further say that not a little of the interest and beauty of such borders depends on this variation. Sameness is the marked characteristic of the one, whereas diversity and individuality is that of the other. In this variation we have really one of the happiest coincidents in the formation of a border of this sort, as we are not governed by any fixed laws, nor are we obliged to exclude plants that may, by their nature, claim a wide diversity of development under different conditions and circumstances. Admitting, however, that diversity and individuality are the all-important points of an herbaceous border, there ought and must, indeed, to be effective, exist a certain prevailing tone of regularity—both as regards colour and development—something to indicate that the elements which Nature has so amply provided have been turned to the best and most effective account. In planting an herbaceous border the chief points to be studied resolve themselves into three, viz.:—colour, height, and season of blooming. Now the first of these is, in general, easily and correctly ascertainable from books and catalogues, and the broad principles that govern taste in the arrangement of colours being pretty well understood, I need not dwell upon this, except to remind my readers that along with colour the season of blooming must be taken into account, as a blue spring flower will not in the least interfere with a summer flower of the same colour, much less with an autumnal one, if they are placed side by side. As regards height, the matter is not so easily settled; true, the same catalogues give information upon this point also, nor is it any fault of the compilers if their information be not always correct. Amongst herbaceous plants I have seen the same identical species growing 4 feet high in one garden and 9 feet in another, the difference arising, to some extent, from the character of the soil, but more especially from that of the sub-soil. Then, again, a plant may attain an unusually great height the second year after planting in a newly-formed border, but will in a year or two revert to its normal development as the soil becomes exhausted; hence any local exuberance of growth as to height must be dealt with by placing such a plant a rank or two further back in the border. Let it, however, always be borne in mind that too much regularity in height will lead to a formality which ought to be absent from the herbaceous border. As to the season of blooming, though certain variations in respect of the seasons themselves, as well as the local peculiarities of climate, may cause considerable alteration, the main point to be aimed at is to distribute the plants that represent the seasons in the broad recognised sense of spring, summer, autumn, and winter, over the entire length of the border. If this be not attended to, half a dozen autumn flowers may be placed together, rendering one portion of the border gay at the expense of the remainder. The same remark equally applies to the plants of any other season. I have in the outset stated that, in all herbaceous borders, there ought to exist a certain amount of regularity, with a view to distant effect. This can easily be obtained, without by any means interfering with that variety of material, both in flowers and foliage, which give a special interest to the close observer. How this may be attained one or two examples will readily explain. Take the first rank; every one is familiar with the carpet patches of purple and white formed by the *Aubrietia* and *Arabis* in early spring. Now, if these are planted alternately and equidistant—say 12 feet apart—along the border, they will give all the effect of regularity, and yet leave

plenty of space between for other dwarf-growing plants. Take, again, for the third rank, such a plant as the fine garden variety of *Lythrum*, which continues in bloom for at least three months, and alternate it with the beautiful white autumn-flowering *Anemone Honorine Jobert*. The former I select, as a plant of taller growth, to stand well above the general height of the row. Let these be planted at distances of 15 feet apart, all along the border, and they will give all the regularity requisite. In the fourth row, the tall bright yellow *Achillea Eupatorium*, with its pretty Fern-shaped foliage, may do duty alternately with one of the tall-growing *Larkspurs* planted at similar intervals, or, perhaps better still, with the *Macleaya cordata*, whose lovely foliage is suffused with a rosy hue, as though it were continually reflecting the glories of the setting sun. For the back row, you have your *Hollyhocks*, your *Polygonum Sieboldi*, and some of the tall autumnal *Asters*, which may be so arranged as to present that continuity which ought to make itself visible all along the border. These plants I have selected as continuing in bloom for a long period and for possessing certain points that peculiarly adapt them to the purpose. There are many others. I merely use these as an illustration of the mode of carrying out the principle. I wish to establish a principle that I think is too often lost sight of. The time for planting is now fast approaching; but if, as is generally the case, your plants are in pots, my advice is not to be in a hurry; give your border plenty of time to consolidate; the end of March or beginning of April will be soon enough. If the plants are in pots, carefully disentangle the roots as you plant; this operation, though perhaps a little tedious, will sometimes save a season; and, above all, be not too sanguine about the success of your newly-formed border the first season, but remember that there are some herbaceous plants that will take two or even three or four years to recover a removal; and, further, that those plants usually live the longest and are the most valuable—in illustration of this you may take any of the tall-growing *Gentians*. I mention this, as many people used to the rapid growth of our bedding plants are too apt to expect the same from their herbaceous plants, whereas the latter are to last for as many years, or terms of years, as the former do months.—J. C. NIVEN.

Flower Garden and Pleasure Grounds.

Owing to the cold and sunless weather which has prevailed during the first half of this month, the growth of spring-flowering plants and bulbs has been considerably retarded; and in some instances a slight protection may have been found necessary, especially as regards early bulbs and other spring-flowering plants, and such shrubs as the *Chimonanthus* and *Jasminum nudiflorum*, early-flowering scarlet *Rhododendrons*, &c. As soon as a favourable change in the weather takes place, such protections should, however, be removed. When fine weather has set in, lawns should be again well swept and rolled; Grass edgings to walks should be lowered where necessary, and rendered solid by being well beaten down with a turf beater, and immediately afterwards they should be neatly and carefully edged. Finish, as soon as possible, any new work or alterations which may be in hand; and during frosty weather turn frequently the compost heaps, which should be in preparation for the flower beds and borders, and which should be ready to be applied as soon as the bulbs and spring-flowering plants are removed from them. If not already done, prepare beds for *Ranunculuses*, by removing the soil to the depth of 18 inches or more, and if the situation is in any degree damp, put in the bottom 4 or 5 inches of some rough material to act as drainage, such as brick-bats or lime scraps, and on this place some sods or litter to prevent the soil from mixing with the drainage; on this should be placed a portion of sound maiden loam and well rotted hotbed manure or dried cow-dung, together with a portion of the original soil; this should be, to some extent, incorporated together without, however, bringing the loam and manure to the surface. When the soil has become well settled, drills not exceeding 2 inches in depth should be drawn some 5 or 6 inches apart, and the roots should be placed in the bottom of the drill with their claws downwards, and pressed gently down at a distance from each other of about 3 inches; if the soil is at all heavy, the roots may, with advantage, be slightly covered with a mixture of finely-sifted leaf soil and sharp river sand. The drills should now be filled, in pressing the soil gently down with the hand and raking the surface of the bed smooth and level. Top-dress *Pinks* and *Pansies* in beds, and fill up any vacancies which have occurred. Let bedding *Pelargoniums* of all sorts, which may have been inserted as cuttings round the sides of pots some 5 or 6 inches in diameter, be now potted off singly; and, if possible, they should be placed in some situation where they can have the advantage of artificial heat until they have become somewhat established in their pots; they may then be placed in cold pits or in any other position where they can be protected from frost. The

variegated and tricolor sorts should be treated in the same manner; but, as they are more tender than the green-leaved or zonal kinds, they will require more care. Single plants of these sorts, in small or 3-inch pots, may with advantage be shifted into pots of larger dimensions in order to have the plants of considerable size when planted out. Cuttings of trees and shrubs of various kinds, such as *Poplars*, *Willows*, *Privets*, &c., should now be put in; while *Limes*, and other kinds of trees, which are usually increased by means of layers, should, when well rooted, be separated from the stools, and the roots should be carefully trimmed and planted in nursery lines, as should also the one year's seedling forest trees of various kinds. Prepare clay for grafting, and take off scions of ornamental trees and shrubs which it may be intended to increase by this means, such as those of the *Acer Negundo variegatum*, variegated *Elms*, and weeping trees of various sorts. Place the end of such scions in the soil in a shady situation in order that they may keep fresh until the sap is fairly in motion in the stocks on which they are intended to be worked, an operation which should be performed about the middle of next month.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Indoor Fruit Department.

Vines.—Pot Vines swelling their fruit should be liberally supplied with manure-water at every alternate watering. This has a beneficial effect on the swelling of the berries; and so has a thick top-dressing of manure. For this purpose, half-rotten cowdung is best, and when the pots are too full of soil to admit of much manure being applied, it may be built up, in the form of a cup, a few inches above the rim—a shape which will admit of water being given. If the fruit is wanted before it is likely to be ripe with ordinary forcing, the heat may be increased 5° or so. When the fruit and wood are fairly formed a little extra heat has not the same weakening effect as it has when given previously to their having attained that stage. Every favourable opportunity should be taken to admit fresh air to all growing Vines, shutting up early in the afternoon. A temperature of 80° is not too high at this time. Continue to pinch and tie the shoots, and to thin the fruit, as these operations become necessary. A genial moist atmosphere has a beneficial influence on all young growth, and has at the same time a tendency to keep down insects. In dull weather the foliage should not be syringed. Damping the pathways and keeping the evaporating pans full will be found to produce sufficient evaporation. Probably Vines that have been cut back may not start simultaneously into growth; each plant must, therefore, be lifted out of the bottom-heat in which it is growing, when the height (18 inches) previously recommended has been attained. As soon as a few roots have been formed, keep the temperature well up about Vine eyes, and, until the pots are well filled with roots, keep them rather dry than otherwise.

Pines.—As regards these, a general shift will shortly be necessary, and then the ball of every plant should be examined in order to ascertain in what state the roots and soil are. It is desirable to have the roots in a healthy-growing condition at the time of shifting, and, when the soil is not much exhausted and is well filled with roots, the ball will not require reducing while potting. These should now have a copious watering, as this is the last they will get until they have rooted into fresh soil. The soil in which Pines are to be potted will be benefited by an occasional turn over, and fresh plunging material should also be secured. Where leaves are used for this purpose, they should be turned where they are stored a week or ten days before they are removed to the Pine bed. Unless on extremely cold nights, the temperature in which Queens in fruit are placed should not be lower than 70°, and 15° above that is not an excessive heat at shutting-up time on a mild sunny day. Remove all the small gills and little sucker-like growths as soon as they appear around the base of the fruit.—J. MUIR.

Fruit Rooms.

Apples and Pears are now getting scarce, and as many weeks must elapse ere any considerable quantity of fruit will be available for dessert, increased care should be exercised to prevent decay. The stores should be examined at least once each week, clearing out all rotten fruit, and any that is even partially decayed should be at once sent to the kitchen for immediate use. Ventilate freely for a couple of hours every day, when the state of the atmosphere permits, remembering that rain, fog, or damp of any kind, and also keen frosty air, should be scrupulously excluded. On some kinds of Pears, through the wet season, mildew has been troublesome; the best remedy I have yet found is to gently wipe each fruit with a dry cloth, which is not nearly so formidable a task as it may be thought, as a handy boy will do several hundreds in a day. *Easter Beurré*, *Joséphine de Malines*, *Ne Plus Meuris*, and *Bergamotte d'Espéren* we are now sending in for dessert, all of which are in a good state of preservation and of super-excellent quality. *Beurré Rance*, at one time considered a fine dessert Pear, has in this

district been placed amongst those for stewing, of which it is one of the very best; but this season it is equal to the best dessert kinds, showing conclusively how dependent, as regards quality, all fruits are on the character of the summer and autumn. The best dessert Apples now in are Newtown Pippin, Pitmaston Russet, Sturmer Pippin, Court of Wick, and Ashmead's Kernel. Kitchen Apples now in use are London Pippin, Northern Greening, Wellington, Rymer, and Bedfordshire Foundling. If it be desired to keep for a length of time any particular kinds of Apples or Pears, they should be wrapped separately in tissue paper, and placed in air-tight drawers or boxes. By this means I have known Apples preserved for a whole year. Grape rooms are not yet so common as they ought to be, and will assuredly become, as soon as the merits of preserving Grapes in bottles of water is better known. The whole of our Grapes were cut five weeks ago, and I have to-day (February 13th) looked them closely over, and out of some 200 bunches, I have cut out, perhaps, a score of bad berries, certainly not more, although it is a fortnight since they were last looked over. Had this quantity of fruit been hanging on the Vines, we should, in addition to firing, airing, &c., have had to examine them almost daily, and probably cut away six times the quantity of mouldy berries, keeping out of the question the fact of the Vines being at rest, and the house available for bedding plants, &c. The Grapes should be cut with a portion of wood attached (the longer the better) and inserted in bottles of water, fixed in a slanting position, so as to allow of the Grapes hanging clear of them. The wood in front of the bunch is, for the sake of neatness, frequently cut off, but this practice should be discontinued, as it retards the circulation of sap. The difference here last year was very marked between those bunches having the front shoot cut off and those upon which it had been left, the advantages being greatly in favour of the latter. Thorough ripeness is indispensable to good keeping, indeed, it is the one great secret of the system, and when, as I am sometimes, told of failures and asked how it is my Grapes keep so well, I invariably answer—because they are thoroughly ripened.—W. WILDSMITH.

Kitchen Garden.

Cauliflowers, wintered in frames, may now be planted out under hand-lights; it is almost impossible to make the land too rich for them. Station planting may be advantageously adopted if the land is not in first-class condition; mark out the stations or positions, where the hand-lights are to stand in rows, 4 feet apart, and 3 feet from each other in the rows. Dig holes about the size of the hand-lights, 18 inches deep; put a barrowful of manure in each hole and make the soil level; take the plants up carefully with balls, and put four plants under each light. Those plants put out in the autumn under hand-lights may be thinned out to four under each glass, and the thinnings planted elsewhere; dustings of soot round and about the plants will be beneficial, and abundance of air should be given on all favourable occasions. Cauliflowers may also be planted in trenches, and if some warm stable manure can be had, good early Cauliflowers may be obtained in this way. The trench should be 5 feet wide and 18 inches or 2 feet deep; and the width will admit of three rows being planted, one along the centre and the other two 1 foot from each side. In casting out the earth the highest ridge should be laid on the side from which the coldest winds blow. Warm manure, to the depth of about 1 foot, should be placed all over the bottom, and then covered with 8 inches of soil. When planted, the plants may be protected in cold weather by means of old lights, oiled calico, straw or reed screens, or, if nothing better can be had, Spruce or Yew branches; even Pea sticks laid across the trenches will afford a good deal of shelter. Planting in trenches is a good plan to adopt in dry soils, as a good opportunity is afforded for applying liquid manure. Peas and Beans that have been raised under glass may be planted out in the warmest and most sheltered positions that can be had. Select a calm day for the operation, and when the planting is finished lay a ridge of dry soil along each side of the rows; place sticks not exceeding 3 feet high to such kinds as Ringleader and William the First, and the trimmings from the long sticks might be used for such kinds as Gem and Tom Thumb. Although sticks may not be absolutely necessary for the latter, they are more productive when kept off the ground, and they will also afford considerable shelter. As a further precaution, Spruce or evergreen branches, about a foot high, may be placed on the windward side. Beans may be protected in a similar way. Clear off all old crops of Cabbages or winter Greens; manure and dig the land for Potatoes to be planted next month. Celery may be taken up carefully with the roots, as far as is possible, entire, and laid in thickly in ashes or old tan under a north wall. In such a position it will keep in good condition a long time, as it will be less influenced by a rise of temperature when it occurs, and the land may be prepared for the next crop, which will be well suited for Carrots or

Cauliflowers. Jerusalem Artichokes may be planted now at any time; although this is a crop that will grow in almost any position, like everything else it pays best with good culture. In heavy land draw drills 3 feet apart and 2 inches deep, place the tubers 1 foot apart in the drills, and cover with a hoe, drawing the earth from each side over them, so as to form a ridge about 5 inches deep over the sets. Sow a few Leeks of the Musselburgh or Ayton Castle varieties for early planting; also the early Ulm Savoy. Capsicums may be sown in pans in heat, as also Tomatoes. Cuttings may be taken from the latter when stock plants have been kept through the winter, as plants so raised generally come into bearing first. Successional Mushroom-beds may still be made up in the house, and, at the same time, also, a bed might be made up in an open shed in a north aspect. There is no occasion to wait for the beds to decline to 65° before the spawn is inserted, as the moment the heat falls below 90°, and is still declining, the bed may be safely spawned, and much time gained. Of course, beds in a cool place will require more attention to coverings in order that the temperature may be kept regular. Provide a good stock of Cucumber plants for frame and pot plants. Hot-beds that have been used for Asparagus forcing, and that have lost most of their heat, may be planted with Lettuce, Potatoes, or Carrots, or they may be turned over and fresh manure added and used for forcing other crops requiring more heat, and for pricking out Celery.—E. HOBDAV.

EXAMINATION PAPER FOR STUDENTS ON BOTANY.

By the INJUDICIOUS HOOKER.

1. Why is the Gardenia so called, since it grows, not in gardens but in ladies' hair and young swells' button-holes?
2. What is the difference between the Broccoli and the Cauliflower? Has it anything to do with that which exists between a crocodile and an alligator, or a solicitor and an attorney?
3. Distinguish between Venus's Bath, Venus's Comb, Venus's Hair, Venus's Fly-trap, and Venus's Looking-glass? What kind of flies are usually caught in *Dionæa muscipula*, or Venus's Fly-trap? Do not "detrimentals" often escape? What sort of ladies are fondest of the *Specularia*, otherwise known as Venus's Looking-glass? Is ugliness their usual characteristic?
4. There is a species of *Phalaris* known as Gardeners' Garters. Does it give its name to the Order of Knighthood conferred on those famous gardeners, Sir Joseph Paxton and Sir William Hooker.
5. Is the *Ormosia* or Necklace tree worth cultivating by jewellers?
6. *Atriplex*, *Anthyllis*, and *Plantago* are known as Lamb's Quarters, Lamb's Toe, and Lamb's Tongue. Mention the London butchers from whom they can be purchased.
7. Lady students are requested to give the Latin equivalents for Lady's Bedstraw, Lady's Comb, Lady's Cushion, Lady's Fingers, Lady's Garters [*Honi soit!*], Lady's Glove, Lady's Hair, Lady's Laces, Lady's Looking-Glass, Lady's Mantle, Lady's Nightcap, Lady's Slipper [ah, how long since Mr. Punch played "Hunt the Slipper"!], Lady's Smock, Lady's Thimble [true ladies are not ashamed of the thimble, though vain young lady minxes are], Lady's Tresses, and Lady's Thumb.
8. Classify with care the two unique species, *Gladstonia morosa* and *Disraelia gloriosa*.—"Punch."

Sunken Boilers.—I am astonished that these boilers have not been condemned long ago by your practical horticulturists; but I suppose that custom and routine are, in England as elsewhere, hard to break through. For my own part, I see no reason for burying the boilers. Why not use the portable upright slow-combustion stoves, like those made by Read, Deard, and others of your able constructors? That apparatus is here called the Thermostat thermosiphon. For the last ten years I have always used one. It is placed in a small room, which serves me as library and writing office. Next to it is another small room, which separates the office from my greenhouse, and the pipes pass through the two walls. My greenhouse measures 30 feet long by 12 feet wide, and the length of the 4-inch cast-iron pipes is about 160 feet. The house has not been covered this winter; and, although we have had some severe frost in December and January (8° Fahr. out of doors) the temperature inside remained above the freezing point. This apparatus has the advantage of being portable and economical, and of not requiring any fixing, and but little attention. Mine is about 3 feet in height and 1 foot in diameter in the interior. At night, about eight o'clock, I fill it with coke, suppressing nearly all draught, and the next morning, at seven o'clock, I find the fire still lighted. I always attend to it in the day, so as to have more heat than at night, although I see my neighbours do the reverse. They most likely have never observed that, even in the warmest climate, the nights are much cooler than

the days, and that plants want their night's rest as well as animals. I have learnt from experience that gas-coke is the best fuel for these stoves; but it must be broken, as regularly as possible, in small pieces about the size of a Walnut. If I could obtain coke without stones, I might light my fire on the 1st of October and keep it burning until the 1st of April. I now clean the apparatus once a week, and light the fire again. I expend coke to the value of 6d. in twenty-four hours. The price of coke here is 3s. 3d. per 200 lb. The draught of the chimney must be checked, and the coke must consume slowly to produce its effect. These stoves are particularly useful for amateurs who, like myself, attend themselves to their plants, but object to getting up at night to look after their fires. My opinion is that this apparatus ought to supersede all other methods of heating greenhouses.—JEAN SISLEY, Lyons.

The Artichoke a Remedy for Rheumatism.—In the "British Medical Journal" for December 19, Dr. Copeland, of Norwich, has published some cases confirmatory of a former paper recommending the treatment of rheumatism with the common Artichoke in the form either of tincture or extract. These are prepared from the leaves gathered just before the vegetable is fit for food, and whilst they are full of juice. If the leaves are left until the top is cut off for cooking purposes, and the plant begins to wither, the product is useless and inert. To this circumstance Dr. Copeland attributes the negative results met with by some practitioners.

Home-grown Tobacco for Purposes of Fumigation.—Ordinary Tobacco, as used by smokers, has undergone a certain amount of fermentation. In America, immediately after the plants are cut, they are hung upon lines stretched under open sheds to dry. When dry, they are next taken down, sprinkled with water, cast into a heap, and allowed to remain until a proper degree of fermentation is attained. The fermentation is then promptly arrested by again hanging them over the lines to dry. The above process is repeated two or three times in succession, when the leaves are ready to be packed for the use of the tobacconist. I am afraid, however, that home-grown Tobacco will be found to be totally useless for purposes of fumigation, manipulate how one will. I have repeatedly tried some grown in my own garden in the north of England, and have found it no better than the same amount of brown paper, owing to the non-formation of the poisonous essential oil—nicotine—in plants grown in these cool latitudes. I was myself puzzled to know the reason why our own tobacco should differ so widely in taste, smell, and effects from the ordinary weed, when tested in a pipe, and the microscope solved the mystery. For the benefit of those who may not be conversant with the subject, I may explain that the nicotine is alone secreted and contained in minute urn-shaped knobs, situated upon the tips of the hairs which thickly cover the epidermis of the whole plant—both stem and leaves; and that the peculiar effects of tobacco, either when smoked or used as a fumigant, almost entirely depend upon the presence of this principle. On submitting (says a writer in the "English Mechanic") a portion of sound Virginian Tobacco leaf, even after having undergone all the various processes of manufacture, to the microscope, these urns will be readily seen terminating the hairs. Now, on examining the plants grown in my own garden, I discovered that these capillary urns were almost entirely absent, with the exception of a few sparsely scattered at rare intervals upon the stem and under-side of the mid-rib of the leaves—due, no doubt, to the comparative coldness of the climate—although the plants were, in every other respect, vigorous and well developed, the hairs all over the leaves, with the exception named, terminating in sharp points, like needles, in place of urns. Hence the unsuitableness of home-grown Tobacco for ordinary uses.

PERSONAL.

GOLDEN SQUARE, we understand, is about to be remodelled by Mr. Bromwich, of 25, Buckingham Palace Road.—Mr. William Lewin, brother to Mr. H. W. Lewin, Drumpellier, succeeds Mr. Michael Gray at Aske Hall (Earl of Zetland's), from Upleatham.—Mr. McKenzie, of Alexandra Park, having nearly completed the outdoor works and glass structures there, is prepared to take commissions in landscape gardening and the improvement of landed estates. He will still continue on the official staff of the Alexandra Palace Company.—Mr. Smith, many years gardener at Exton Park, is about to take charge of the extensive garden establishment at Mentmore, the seat of Baron M. de Rothschild.

OBITUARY.

We have to record with much regret the death of Lady Cullum, at Hardwicke House, Bury St. Edmund's, on the 16th inst. Mr. Fish thus informs us of the suddenness of the sad event. He says, "Her ladyship was with me in the garden yesterday till three, and was in good health and spirits; but, after she went into the house, she was taken ill directly, became insensible, and never rallied." Lady Cullum was devoted to horticulture, and had a charming garden.

NOTES AND QUESTIONS.

[Many notes and answers, obligingly sent us by correspondents, are unavoidably omitted this week from want of room.]

Narcissus pachybulbos.—Some of your readers may like to know that this Algerian plant is now in bloom in Mr. Munby's garden at Alice Holt, Farnham, for the first time in this country.—H. HARPER CREWE.

Continuous-blooming Indoor Roses.—Can any of your correspondents give me the names of a few Roses that will bloom all the year round in a greenhouse?—T. O. R.

Grafting Magnolia Campbelli and Lenne.—When should I graft these, and which is the best stock to graft them on; also, how should I afterwards treat them?—G. H.

Orchid Baskets.—For the information of "Devonian" and others we may state that the rustic pottery-ware Orchid baskets alluded to last week (see p. 143) are manufactured by Mr. Matthews, of Weston-super-Mare.

What is the Maze Berry?—Can any of your readers tell me what this fruit is? A clergyman, who resided ten years in Jamaica, tells me it is the finest of the tropical fruits, and is produced by a small tree. Neither the "Treasury of Botany" nor "Lindley's Vegetable Kingdom" allude to it.—W. T., Ipswich.

Mistletoe Seed.—Can any of your readers assist me to some fresh Mistletoe seed? I should be happy to exchange seeds of hardy plants for it, or plants of *Pentstemon ovatus* and *speciosus*, *Aquilegia arctica*, *truncata*, or *Skinneri*, *Primula japonica* or *farinosa*, &c. Address, GARDEN OFFICE.—SALMONICEPS.

Large Persian Cyclamens.—We have received from Mr. Williams, Victoria Nursery, Holloway, some of the largest and best blooms of *Cyclamen persicum* we ever remember to have seen. They belong to the variety of *C. persicum* called *giganteum*, a name which they well deserve, being not only in substance but in size a great improvement on the ordinary type.

Planting Large Camellias in Conservatory Borders.—We are thinking of making a border in our conservatory (doing away with the old shelves), and planting in it old plants of Camellias. Will some of your readers tell me what is the best time to do this, and whether or not it would be best to shake all the old soil from the roots or simply open the balls with a stick?—N. H. P.

Iris reticulata Indoors.—I have this now in bloom in a pot from bulbs potted up in November. Thus it blooms almost as early as *Scilla sibirica*, and simultaneously with *S. bifolia*, grown in a cold house. It is seldom met with, notwithstanding the beautiful flowers which it produces in a cool house or frame at this very early season. Its flowers reach to a height of 6 inches, are of a rich bluish-purple in colour, with bright orange throat, and would be very effective in bouquets or in ladies' hair. It is one of those early hardy bulbs that all should grow.—A. D.

Vine and Peach Destroying Maggots.—I have sent you some maggots, and a specimen of their work on Vine and Peach tree roots. They are very numerous. Could you inform me what they are, and what will kill them without damaging either the Vine or the Peach. In the case of the Vine, the maggot eats the roots, and, in the weevil state, ascends and eats the young shoots.—THOMAS BOYD. [This is the larva of an *Otiorynchus*, possibly *O. sulcatus*, but more probably some other species. If our correspondent would breed some of the larvæ, and send us the perfect insect, it would be very desirable.—A. M.]

Winter Broccoli.—It is sometimes recommended that late Broccoli should be planted thickly, in order that they may shelter each other during severe weather. This is a mistake; the destructive effects of the late frost will afford a very useful lesson in this respect. Thick planting encourages weak soft growth that soon succumbs to cold, but where the plants have stood 3 feet apart, or even at wider intervals, the growth is dwarf, firm, well matured, and in a better condition, generally, to resist extreme cold. Being dwarf, a covering of snow affords greater protection, and the loss, consequently is trifling.—E. HOBDAY.

Psidium.—This name is now appearing in various mediums for advertising, and has already elicited some speculation as to its pronunciation and meaning. It should be pronounced *Psidium*, by no means *Psidi um*, as some suppose; and is the name given by botanists to a genus of which the Guava is the best known representative. The title owes its present prominence to the fact that it has been chosen by Messrs. Piesse & Lubin, of New Bond Street, as the designation of a new perfume which they are about to issue, and which is likely to become as popular as the "Opoponax" with which the same firm puzzled people in general a few years back.—B.

Zinc Garden Labels.—We have received from Mr. Yeats, of Willow Cottage, Mortlake, specimens of zinc labels, light and neat in shape, and of forms suitable for pots, walls, or for suspending from Standard Roses or other trees. The latter are fixed to the tree by means of stout leaden wire passed through two holes in the label, which is thus firmly held in a readable position, and at the same time secured in a double manner to the tree. On samples of these labels, exposed to all weathers since 1868 and 1870, the names are as legible as when first written. Labels of this kind are cheap, durable, and the ink apparently indelible.

Great Scotch Firs.—Few are aware that this tree attains such proportions as it does in many places in the north of Scotland. On referring to the forest of Glenmore I find I did not give the dimensions of the skeletons still standing there denuded of bark; the boles of many of these measure above 20 feet in circumference. There is even now in Scotland many fine Firs likely to attain these dimensions. At Dornaway Castle, the seat of the Earls of Moray, there is a noble tree of this description of Fir 15 feet in circumference, and 50 feet in height without a branch. At Inverary Castle, too, there is a tree 115 feet high, with a circumference of 13 feet 6 inches at 3 feet from the ground.—J. T.

Grafting Walnuts.—How can a remarkably good Walnut be propagated?—H. MEADE-KING. [In the climate of England, and even in that of Paris, I only know one method of propagating the Walnut with any chance of success. This is by grafting, or by inarching. By means of cleft-grafting, whip-grafting, and crown-grafting, I have sometimes succeeded, but seldom in proportion to the number of trials. The difficulty felt here in propagating the Walnut by grafting arises from the fact that the wood of the grafts is not sufficiently ripened. In the south-east of France, where the summers are hotter, and where Walnuts are an article of extensive commerce, an ordinary operator succeeds in fifty cases out of a hundred, and it is whip-grafting that is most frequently practised, but flute-grafting is also employed. These remarks wholly apply to open air culture. There is also a chance of succeeding with the Walnut by means of plants cultivated in pots, which are grafted in the spring under cloches, very much in the same way as *Rhododendrons*, *Oranges*, and numbers of similar plants; but, by this plan, one ought to be satisfied with very moderate success.—F. D. JAMIN, Bourg-la-Reine.]

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare*.

GRAPE GROWING IN THE OPEN AIR.

ONE cannot read of the system of Grape culture pursued by the French in the vicinity of Paris, which is fully described in "The Parks, Promenades, and Gardens of Paris," and also by the late Mr. Thompson, of Chiswick, without coming to the conclusion that their success is largely due to French thrift and industry. Their methodical way of training the Vines so as to cover every inch of wall surface, and enable them to calculate exactly the number of bunches to be had from a given area; their painstaking system of pinching the shoots in order to regulate the vigour with the utmost nicety throughout the whole tree; their cheap and expeditious manner of thinning the berries; and their somewhat primitive but effectual protective and other appliances, remind one of the thrifty and plodding Chinese agriculturists we read of, and indicate a settled and profitable industry handed down from sire to son, with little or no change, for generations. Mr. Thompson states (p. 676 of the "Gardener's Assistant") that as many as 320 bunches can be produced on a surface little more than 8 feet square. Of course the bunches are only middle-sized; but what a quantity! Is any such instance of systematic heavy cropping under glass even on record in this country? Mr. Thompson was a conscientious writer, and not likely to exaggerate in such a case. The same authority also states that the training and stopping of the shoots is conducted so methodically, and with such periodical regularity, that the quantity of foliage on each plant is, year after year, almost uniformly the same. Both plants and shoots, too, are restricted to a limited space, but apparently restriction produces none of the ill effects usually ascribed to it. No doubt the Thomery Grape growers have some advantage so far as climate is concerned, but not much in mean temperature, at all events. Possibly a rather more constant sunshine constitutes the only real difference in this respect, and it would be unfair to credit this advantage with more than a fractional part of the success which is attained. We must, I think, rather attribute it to that faculty which the French possess for turning circumstances to the best account, and for making the most of trifles—a faculty which often enabled the French soldier, in the dark days of the Crimean expedition, to extemporise a dinner or a salad out of a few materials, when his English comrade had to go without; and the same power of adapting means to ends is said also to constitute the difference between an English cook and a French one. The fact exists, at all events, that Grapes of fair quality can be grown out of doors in England; but since Vineyards disappeared instances of anything beyond a slovenly attempt at out-door Grape culture are exceedingly rare, and yet many a proprietor and cottager might make it not only a source of pleasure, but of profit. Local horticultural societies might accomplish practical results in fostering Grape culture with the class among whom they seek to encourage a love of gardening. I can personally testify that the system of offering small prizes for the best kept gardens, adopted on some gentlemen's estates, is attended with the very best results. I speak within the truth when I say that some of the best cropped gardens, best vegetables, and best hardy fruits I have ever seen, belonged to cottagers who were encouraged in this way. The prizes were almost nominal. The "honour of the thing," and the prospect of receiving a kind word of approbation from the squire, soon came to be the ruling motive among the competitors. It has often been difficult to determine, in our own experience, who deserved a prize; but a word of commendation or praise, or a mere exhibition of interest in any special feature deserving of notice, never failed to stimulate and encourage to still greater exertions. Now I would suggest some effort of this kind in those districts where there is a probability of Grape culture succeeding. The Vine is easily propagated, and those who are disposed to assist their cottagers and neighbours need be at no further expense than is entailed by striking the Vine cuttings and giving

them away. Unfortunately, modern writers on the Vine have not generally contemplated its culture in the open air in England among the humble and rural population, and, while their teaching has been adapted to the purposes for which it was intended, it has undoubtedly had a tendency to create an impression among the uninitiated that Vine culture was an awful mystery. It is well, therefore, to state here that the Vine, though it does not ripen its fruit in some parts of Great Britain and Ireland, is perfectly hardy, and, wherever its wood attains sufficient maturity, it is one of the most certainly prolific fruits with which we are acquainted. It will also thrive well in any ordinary garden soil that is generally suitable to common vegetables; but its vigour and fruitfulness will of course depend upon the cultural treatment it receives. Further, it is easily trained, grows rapidly, and begins to bear fruit at an earlier age than almost any other hard-wooded fruit tree. In short, it may be said that the chief obstacle to Grape-growing anywhere in England is the ripening of the wood. Whenever the summer shoots get brown and tolerably hard by October or November a crop of fruit is ensured; and this ripening is a question of summer heat and summer pinching and training. The French growers are, it appears, satisfied if the base bud on each shoot, to which they cut back in winter, is thoroughly ripened; and that this much and more can be secured in many parts of this country, against walls and cottages, with the earlier kinds of Grapes, is a fact beyond dispute. It is important to note this; for, as a rule, the annual shoots of the Vine ripen contemporaneously with the fruit, and where the one ripens the other will. Having said this much in order to remove some very prevalent but false impressions concerning the Vine, I may give a few practical hints on culture. Though the Vine was formerly grown in the open ground, espalier fashion, in this country (an argument which should surely encourage us to expect some success against walls now), I am not going to recommend the practice here. Whoever has got a wall, however, or, what is better, a warm house-front or gable end, facing to any point between south and south-west, may attempt Grape culture. Possibly, a line drawn across the country about the northern limits of Nottinghamshire or Lincolnshire would represent the northern boundary within which success might be expected, though, doubtless, there are many favoured nooks much further north where Grapes might be ripened. The Black Hamburgh is not by any means the earliest Grape, and consequently is not suited for out-door culture everywhere; but I have seen it ripen its fruit on the front of a cottage about Worksop, where it was trained intelligently by the proprietor. I have also seen fairly finished bunches of the same variety grown against the chimney stack of a forcing pit as far north as Dumfriesshire. About London and further south no doubt such instances are numerous. On the sloping roof of a tiled house in Kent a friend of my own had an old Vine that regularly ripened a quantity of Grapes, though it certainly did not receive the attention it deserved. As the Vine, when grown out-of-doors, is not likely to grow so luxuriantly as under glass, and as it is not desirable that it should do so, the border need be neither so deep nor so rich as Vine borders are usually made. Good ordinary garden soil, such as is found to produce fair crops of such vegetables as Peas and Potatoes, and in which other fruit trees grow well, will do. If chopped turf can be had to mix with it, all the better, especially if the soil be light; or, if it be old, kitchen garden soil in which humus has accumulated. If it be heavy, well-rotted stable dung and leaf mould may be added in considerable quantity, and in either case bones or bone-dust will repay application. The border need not be above 12 feet wide, and, I need hardly say, it should be well drained. It should slope to the sun more than fruit-tree borders generally do; and, in order that the sun's influence may be felt on the Vine-roots, it should not be more than 18 inches deep. Some sort of trellis should be provided for training the Vines against the wall. This may be either of wood or wire; the latter is most convenient, and, as the wires can be stretched by anybody, it is not expensive. Whatever material be used, the supports should be stretched horizontally 18 inches apart, and about 3 inches from the wall. These directions are also applicable to house fronts or cottage ends—only that, where but one or two Vines can be accom-

modated, a semicircular piece of ground, about 15 feet wide, will represent the border. In such situations the site is generally sufficiently drained, and, if the ground is deeply and regularly dug over, and enriched with any of the materials before mentioned, it will be in a condition for receiving the Vines. In another number I shall conclude by describing briefly the planting of the Vines, and the simplest and most methodical way of training and cropping, so as to get early and regular returns in the shape of fruit. J. S. W.

SULPHUR OFTEN THE CAUSE OF RUST ON GRAPES.

YOUR correspondent, "J. M." (see p. 150), says he does not believe that sulphur fumes have any influence in producing rust. I confess to having been somewhat startled on seeing such an assertion made by one who is looked to as an authority in such matters. Sulphur itself may be used in any quantity in a house at whatever stage the Vines may be in, without the least injury, provided it be used so as not to come in contact with any heated surface, such as pipes, flues, &c. I have used it repeatedly for prevention of mildew by mixing it with water and syringing it on while the foliage has been in a tender state, and before the bunches have been in bloom, immediately after they were set; and, indeed, in all stages as occasion required. It is only when applied to surfaces that become heated that any danger is to be apprehended, and only then when it becomes sufficiently heated for the fumes to contain sulphuric acid gas, one of the most deadly known to vegetation, as may be seen in the destruction that occurs near large works evolving this gas. That sulphur fumes will produce, and are more frequently the cause of, rust on Grapes than anything else, is a fact known to most gardeners, and many have had to lament the incautious use of it for the purpose of eradicating red spider; I would therefore warn your readers of the risk they run by having sulphur on the pipes or other heating surfaces while the berries are small and tender, and the young leaves susceptible of injury by a little overheating at that critical time. The skins of the young berries at setting, and just after they have set, are so exceedingly tender that a very small matter, such as a slight brush against them by the hair of the head of the person working amongst them; a rush of hot or cold air, or similar extremes; even their own pollen and portions of the flower hanging about them too long at setting time; have been known to cause rust, showing how exceedingly delicate and tender the skin is just at that time, and how imprudent it would be to have the air just then impregnated with sulphur fumes. After the stoning period is the safest and best time to apply sulphur to the pipes for the purpose of keeping red spider in check, and a Vinery must have been badly managed, indeed, if it is required before that time. As to the small bunches on the lateral shoots escaping, that may have occurred from their close proximity to the glass, or from shelter they may have received from the leaves or some other cause just at the particular time mentioned by your correspondent. At any rate, if "J. M." does not mind trying the experiment, he may soon have convincing proof that sulphur fumes are a sure cause of rust if allowed to circulate in the air of the house while the skin of the Grapes is tender and susceptible to injury of that kind. J. SHEPPARD.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

The Mazeberry (see p. 168).—This is doubtless the Jamaica Plum (*Sapota Achras*), commonly cultivated under the name of Naseberry. It is a native of Trinidad, but is cultivated throughout the greater part of the West Indian Islands. The fruits, when dried, are occasionally brought to this country, and are, to my thinking, very superior to French Plums.—J. TYERMAN.

Outdoor Peaches.—The Early Ascot is one of the best for open walls, being very hardy. Its fruit is deep red, large, tender, and well flavoured; it also forces well. Another excellent outdoor Peach is Marquis of Downshire, a mid-season or late variety. Its fruit is deep red, beautifully marked, large, tender, and melting. The tree is very hardy and forces well.—DAVID LUMSDEN, *Bloxholm, Sleaford.*

Knight's Monarch Pear.—Though by no means new, this is a Pear which should be in every collection. Its flavour is excellent; it is a good bearer, and it remains longer in season than any other variety. It began to ripen here on the 1st of November, and lasted in good condition for ten weeks. I do not mean to say that all the fruits were ripe in November, but one could always select a dish from them fit for the table. What I wish to state is that they do not ripen all at once like other varieties; I found this Pear to be the latest here, except Prince Albert, which with me is only fit for stewing. Knight's Monarch ripens well as a standard in favourable localities.—J. RUSK, *Tunbridge Wells.*

Ashmead's Kernel Apple.—We have received from Messrs. Wheeler, of Gloucester, specimens of this excellent Gloucestershire Apple, which is one of our best table varieties from November till May. It is a nutty, crisp, medium-sized Apple with a delicious flavour—better, in fact, than anything just now in Covent Garden Market. The tree, which in habit resembles that of a Nonpareil, is very hardy, and well deserving of cultivation.

NOTES OF THE WEEK.

—MR. J. SHERRATT, Knypersley, near Congleton, writes to us to say that the Mangosteen (*Garcinia Mangostana*) is now in flower there, and that the Kumquat (*Citrus japonica*) is also splendidly in fruit in the same establishment, in which it is bearing upwards of 460 ripe little egg-shaped Oranges, and forming a really beautiful object.

—FIFTY guineas are to be awarded in prizes this autumn by Messrs. Hooper, of Covent Garden, for the two Potatoes Snowflake and Eureka, the prizes to be divided equally between them. The conditions under which the competition is to take place will be found in our advertising columns.

—DR. MOORE, writing to us from Glasnevin, Dublin, says:—"We have had remarkably mild weather here of late, which brought out quite a blaze of spring flowers, but they were laid low by 5° of frost on Wednesday night. This climate of ours is unequalled in most respects, but very treacherous during the early spring months."

—MR. HOBDAY, Ramsey Abbey, Huntingdonshire, says, we had 11° of frost this morning (Feb. 24), and signs of more snow. Pears and Apricots are swelling their blossom buds; but all are as yet safe. Fruit prospects, judging from the well-ripened appearance of the wood, and the numerous blossom buds with which the trees are studded, look promising.

—WE hear, on good authority, that at a meeting of the Council of the Royal Horticultural Society, held this week, it was ordered that the prize money due to exhibitors for the past year should be paid. This will be welcome news to some of our readers who have complained to us about the matter. At the same meeting Sir Alfred Slade and Sir G. Chetwynd gave in their resignations.

—"A FINE collection of hybrid *Amaryllis* is now flowering in Messrs. E. G. Henderson's nursery at St. John's Wood. They are principally hybrids of the *A. pardina* section, and may be grown in a much cooler temperature than the ordinary kinds. One of the finest is "E. G. Henderson," a variety with a finely expanded flower, suffused and speckled with crimson-maroon, the segments being tipped with white. Many of these seedlings are strikingly beautiful, and will become exceedingly popular, being easily grown, and effective winter flowering plants.

—DR. MASTERS delivered a lecture, on Wednesday evening last, in the Council Room of the Royal Horticultural Society, at South Kensington, on "Charles Darwin as a horticulturist." He pointed out that Darwin, without being in reality a horticulturist, had, nevertheless, united the observations of gardeners with the researches of botanists in such a way as to enable him to build up theories with regard to cross fertilisation and natural selection of the utmost value to cultivators in their everyday practice. The lecture was illustrated with coloured diagrams and living plants.

—WE have received a flowering specimen of the dusky-coloured sweet-scented *Iris longifolia* from the Rev. J. T. Boscawen's garden at Tregoney, Cornwall, through the kindness of Mr. Tyerman, who remarks that it forms a useful companion to *I. reticulata*, *I. (Xiphion) Histrio*, and *I. stylosa*. *I. longifolia* is of a metallic purplish-green tint, something like that of the wing cases of the Rose beetle, while the tips of the outer segments are of a rich velvety brown. Irises are all, for the most part, easily-grown garden plants, and we are pleased to learn that their nomenclature has been carefully revised by Mr. Baker, who has already done such good service in that way in the case of other popular genera.

—MR. TYERMAN has sent us another charming collection of early flowers from Tregoney, comprising, amongst others, *Narcissus odorus*, *N. papyraceus*, *N. Tazetta* (*Hermione floribunda* of Jord. and Four., Ic.), a splendid large white variety, with clear lemon cups. The flowers of this fine form measure fully 2 inches across, the segments being an inch broad, and much imbricated, and from ten to twenty flowers are borne on a single scape. These were accompanied by a fine specimen of the Summer Snowflake (*Leucojum aestivum*), which seldom blooms until much later in the season. Mr. Tyerman informs us that a large, rich scarlet-flowered form of *Anemone coronaria* is now very beautiful in many Cornish gardens.

—WE reprint, elsewhere, an article from the "Saturday Review," on modern flower gardening. The writer, of course, has his fling at the gardeners, who, however, are by no means so much to blame as those who command or encourage them to follow the course he deprecates. Many a gardener, fond of plants, and with a good knowledge of them, received orders to follow the fashion and to pay no attention to older favourites. We are convinced that most gardeners would be pleased to reduce the "bedding display," as it is called; for it is the most expensive and troublesome mode of embellishing a garden; but it is for their employers to give the word. If some of the labour and expense devoted to the production of this ephemeral decoration were bestowed in permanently embellishing a different portion of the grounds yearly, it would be very much better for gardening and gardeners.

MONKSHOOD AND HORSERADISH.

CASES of poisoning so often arise from the roots of Monkshood being mistaken for those of Horseradish that we have thought it well to illustrate the two, with the view of pointing out the differences that exist between them. Professor Bentley thus directs attention to the characters by which they are distinguished in the "Pharmaceutical Journal":

Monkshood (*Aconitum Napellus*).—The root of this plant is a biennial. It is formed on the side of the root of the previous year during the summer and autumn, and the old root then gradually

Monkshood (*Aconitum Napellus*).

decays. About the months of October, November, December, and January, when the leaves are absent, it possesses the greatest activity, and hence the above months are the best time to collect it when required for medicinal use, and also that period in which its poisonous effects are the most intense. The time, therefore, when the root is most poisonous is that when it is alone liable to be substituted for Horseradish, for when the leaves appear the two roots are not likely to be confounded. In length the root of Monkshood averages about 5 inches, but sometimes it is as much as 8, or even 10 inches if grown in a very luxuriant soil. In form it resembles the cultivated Carrot, or more nearly the common Parsnip, being broad at its upper extremity and tapering gradually downward to a small thread-like point; the upper extremity, on an average, being about the thickness of the middle finger, but frequently an inch or more in diameter. Sometimes the main root divides into two or three divisions, each of which resembles the other. It passes perpendicularly into the earth, giving off from its sides numerous cylindrical fibres, about the thickness of a common knitting needle. In colour, externally, the main root and its fibres are coffee-coloured, or dark brown, or some shade of brown. Internally, it is white. It has no particular odour, being merely earthy. Its taste is at first bitter, but in a few minutes a very peculiar feeling of numbness and tingling is perceived in the lips, cheeks, and tongue.

Horse-radish (*Cochlearia armoracia*).—The root of this plant is a perennial. It is commonly a foot or more in length, giving off from its sides a number of irregular branches of variable sizes, and terminating frequently at its upper extremity in two or more divisions, from which the leaves arise. In diameter above it varies from about half an inch to 2 inches or more; as commonly used, it is about the thickness of the thumb. In form, it is enlarged about the crown, or point where the

Horseradish root.

leaves are given off; it then slightly tapers for a short distance, and becomes ultimately more or less cylindrical, and instead of tapering gradually to a point, as the root of Monkshood, it frequently maintains nearly the same thickness to its lower extremity, and then commonly divides into two or more branches. In other cases, however, it does taper somewhat from its upper to its lower extremity, but by no means, in any instance, so evidently as in the root of Monkshood. In colour, externally, it is white with a tinge of yellow, and whitish internally. Its odour, when scraped or bruised, is exceedingly penetrating and acrid, exciting frequently sneezing and secretion of tears. In taste it is very pungent, especially in autumn and spring, accompanied by a bitter or sweet flavour, according to circumstances; as, for instance, the season at which they are collected, the manner in which it has been cultivated, and the soil in which it is grown. The more important distinctive characters between the two roots may be thus tabulated and contrasted:

MONKSHOOD.	HORSERADISH.
Conical in form, and tapering perceptibly to a point.	Slightly conical at the crown, then cylindrical, or nearly so, and almost of the same thickness for many inches.
Coffee-coloured, or more or less brownish externally.	White, or with a yellow tinge.
Odour, merely earthy.	Odour especially developed upon scraping, when it is very pungent and irritating.
Taste, at first bitter; but afterwards producing a disagreeable tingling and numbness.	Bitter or sweet, according to circumstances, and very pungent.

The roots of Monkshood and Horseradish may be also distinguished by the different appearances they present when scraped with a knife. Thus, the former will then be observed to be of a succulent character, and the scraped portions soon to acquire a pinkish or reddish hue; whilst the latter scrapes firm and dry, and does not alter in colour.

From the above description of the roots of Monkshood and Horseradish, it will be seen that instead of resembling each other, as is commonly supposed, they have scarcely any appearance in common, presenting evident and well-marked distinctive characters in their form, general appearance, colour, odour, and taste. The only resemblance between the two roots, and this is but a slight one, is in the appearance of their crowns, but even supposing it possible to mistake them so far, the other characters of distinction are so well marked, that no difficulty ought to arise in distinguishing between them.

Crassula lactea a Good Plant for Winter Decoration.

This is a plant which is not so generally grown in gardens as one could desire, seeing that it flowers in the greatest profusion, even in mid-winter, in a cool greenhouse or window, for the ornamentation of both of which it has few equals. Small plants of it are, as a matter of course, comparatively ineffective, but, after they have attained size, so as to produce from sixty to eighty white star-like flowers on a plant, it becomes an object both attractive and striking. We have plants of it here three years from the cutting stage in 8-inch pots, that are each producing the number of blooms just mentioned, and which we found useful for the decoration of the conservatory, in which they are much admired. The culture of this succulent is so easy that nobody need experience any difficulty in the matter. It is readily propagated, and grows freely in sandy-loam, in which there is an admixture of broken soft brick and lime refuse—materials more suitable than crocks for this class of plants. The pots should be well drained, and, in order to secure thorough maturity, Crassulas are benefited by being exposed for a time after they have made their growth under glass. Water should be administered sparingly when they are in bloom, but when in active growth they require a liberal supply. A good companion plant to *C. lactea* is *C. quadrifida*, a pretty pink-flowered kind.—ARTHUR COOMBS, Witley Court Gardens.

Modern Competition.—Our very distant relatives, the apes, are beginning to find useful employment in rural economy. A correspondent of a Ceylon newspaper states that large apes are now regularly employed in the Straits settlements to gather Cocoanuts. These monkeys are imported from Acheen in batches, like coolies, and are marched round the plantations by their owners, who let them out on hire. A line is first attached to each of these peculiar labourers, and he is then sent up a tree, where he is said to select suitable fruit with great discrimination, and to twist the nut round and round until it falls to the ground. Each successive fall of a nut is hailed by the hairy operator above with a chuckle of satisfaction. We are afraid the human natives will like this competition as little as the American workmen liked the introduction of their Chinese brethren. As yet, we believe, they have not struck for higher wages

THE FLOWER GARDEN.

THE BEST VARIETIES OF BEDDING PLANTS.

THE names of a few of the best bedding plants may be of some service at this season, as it is now the time to make provision for future requirements in this respect. Geraniums still afford the principal supply of flowers for summer decoration in most gardens. Softer shades than that of scarlet have been much sought after lately, and raisers seem to have no difficulty in producing what is wanted. Various tints of salmon, rose, and pink are now in vogue. Mrs. T. F. Fenn, Mrs. Keller, Mrs. Rogers, Mrs. Musters, Mrs. Turner, Mrs. Holden, Mrs. Gibbons, Florence Durand, and Annie Orton, are at present considerably in advance of many others; whilst Mrs. William Paul, Rose Rendatler, and several more of the same kind have lost favour considerably, and Amaranth, I understand, will soon be in the same position, as I hear that something of a far superior description has been produced. Corsair is the best scarlet I have seen; the colour is extremely rich, and the trusses are produced in profusion, either in pots or planted out. Of the same colour Vesuvius, Glow, and Glorious are good; I could never detect the slightest difference in the three. Bayard, Warrior, Lady Constance Grosvenor, Cybister, Lucius, and the old Stella, are useful kinds, of a reddish-orange colour. Amy Hogg, Trentham Rose, Violet Hill, and Lord Derby, are above mediocrity. I never could observe anything very superior in Le Grand as a bedding kind; the trusses are certainly large, but there are few of them. I do not like double-flowering Geraniums for bedding; when planted out they run more to leaves than flower. Fine-foliaged Geraniums are very suitable for bedding, but when used for this purpose they should not be allowed to flower; the majority of them are not showy. Amongst the newer varieties of these I know none to surpass William Sandy, Abraham Bass, Lady Manvers, and Lucy Grieve; and Mrs. Pollock, Crystal Palace Gem, Castle Milk, Pearl, and Flower of Spring amongst the older kinds. For a creeper or climber Mangles' variegated and Duke of Edinburgh are always useful. I have not mentioned one in every hundred kinds of Geranium that exist, but those I have given are sufficient, both as regards flower and foliage, and belong to many sections of tricolors, bicolors, &c. Centaurea ragusina is too well and favourably known to be lost sight of as a bedding plant. Polemonium coeruleum variegatum is a handsome plant, with leaves like green and white Fern fronds. It is not used so much as it should be, for it is not necessary to keep it hot throughout the winter. Imperial Blue and Tom Thumb Ageratums are amongst the best, and Sedum spectabile should be in every garden, for it blooms late in autumn, when fresh flowers are scarce. It is quite hardy. Tropæolums in general are valuable subjects; T. Cooperi is by far the finest I have seen. From June until October, it is simply magnificent. Excessive heat or wet has not the slightest injurious effect upon it. It should be planted in masses, although it looks well when planted singly, and whether viewed closely or from a distance it is alike pleasing. T. Bothwelliana is a splendid wall variety. Iresine is a dark foliaged plant, well fitted for flower-garden decoration in some places. It does not do well in the majority of places in the north, and seldom grows after it has been planted outside. Dell's Crimson Beet is everywhere far superior to it. Verbena venosa is a grand plant, with a beautiful violet colour. For this shade it is the finest I know, and may be mixed with any other white flowering or foliage plant. Mangles' variegated Geranium is often associated with it, and looks well as a companion to it. Amongst other Verbenas, Violet King is better than Purple King; yet they are both good. Crimson King is also good. Lady Victoria Scott is a very handsome plant that blooms freely; so much so that in autumn it is often difficult to get cuttings from it. Snowflake and Mrs. Holford are both fine whites. There are a great many more kinds in these and other shades of colour, but, for flower gardens, the kinds I have named are, in my opinion, the most suitable. I do not think Verbenas are so much grown now as they were at one time; they should never be planted where rabbits can get at them, or they will constantly remain stunted. Mildew attacks them in a wet season, and heat injures them in a dry one. Although many substitutes have

been introduced for the Calceolaria, I have seen nothing to come up to this plant; yet, where they do well, I know no other bedding flower that possesses the same hue as that of the bronze kinds, such as Gen. Havelock or Ambassador. C. canariensis, Prince of Orange, aurea floribunda, and amplexicaulis are what I consider the best yellows. Where these have failed, I have seen the yellow-flowering Tagetes introduced in their stead; but, at its very best, it will not compare with the Calceolaria, which should be tried in every possible way before it is abandoned. Lobelia speciosa is a valuable plant when bred from a good strain, otherwise it is useless; Trentham Blue is nearly as good. For a neat front line, L. pumila grandiflora is excellent. The great point in using these plants raised from seed is to have them thoroughly true. Dactylis glomerata is pretty and useful; being nearly white, it looks well against such plants as Violet King Verbena. Festuca glauca is of the same order, but its colour, especially in a dry summer, is nearly blue; both are suitable for front rows, and neither should be allowed to flower or seed. The same remarks apply to Gnaphalium lanatum. East Lothian Stocks would, of themselves, give colour and interest to a flower garden. They are during summer and autumn what Hyacinths are in spring flower gardening; they flower early, and continue to bloom late; they look well either when the first flowers are opening amidst the leaves; or further on, when the flowers are so profuse as to hide the leaves. The true Tritoma Uvaria is a stately-blooming plant, which has a grand appearance placed here and there along a back line in a broad border, or massed together. Too much cannot be said in favour of Pansies and Violas for summer bedding. They lack height, and, therefore, cannot take the same positions as the Calceolaria; but, otherwise, the yellow-flowering sorts are excellent. Their colours are very numerous; Viola Dickson's Golden Gem is unsurpassed either by Violas or any other yellow flower. Blues and yellows are the most distinct colours, as Blue Bell, Blue King, Yellow Prince, Canary, and many others. Whites and purples are well forward. For carpet bedding, Alternantheras are the finest plants that can be used. A. amoena is the most beautiful in colour, being lively magenta; but it is more tender than the less highly-coloured A. amabilis, A. magnifica, and A. paronychioides. Where Oxalis corniculata rubra is used, it must be kept within bounds, or the whole place will soon be overrun with it. Pyrethrum Golden Feather is a common plant of great worth. The varieties of Echeverias are so numerous and interesting, that it is difficult to make a selection. E. metallica is much used as a tall kind, and E. glauca metallica, E. pumila, E. glauca, and, indeed, the whole are well worth a place. The same may be said of every kind of Saxifraga and Sempervivum. In planting these succulents, it is best to keep them as much together as possible. They do not mix well with the generality of flowering plants, unless where edgings of them are made. The whole grouped together are very pleasing to look at. The three varieties of Thymus—lanuginosus, citriodorus, and variegatus—are pretty sweet-scented plants for edgings. They stand out all winter, and may be used in the spring flower garden. Coprosma Baueriana variegata is another handsome plant; the leaves are conspicuous, green and white, with a dwarf and somewhat creeping habit. It is difficult to propagate. The best way to overcome this is to plunge the pot containing the old plant in a propagating bed, and layer the shoots which droop over. Bambusa Fortuni variegata might often be planted out with advantage in many places; small plants of it do well for edgings, and larger ones when planted singly. The foliage of the Sensation Chrysanthemum gives a yellowish-creamy shade in a back line when these colours are in request. Antennaria tomentosa is a little gem with silvery leaves. It is quite hardy, and has the peculiarity of looking well anywhere; it is very serviceable for edging, as it is of a creeping habit. Santolina incana is of nearly the same shade, and as pretty in summer. It grows from 4 to 6 inches in height, and is herbaceous. All the Mesembryanthemums are plants of great beauty and interest; M. cordifolium variegatum is, perhaps, best known and most used. Its foliage is very pretty, but not so curious in form or arrangement as that of many others of its kind. It is a pity that Coleus Verschaffeltii does not succeed everywhere; in summer, and after it has got sunburnt, it looks like rows of

exquisitely moulded rich metallic bronze. I have seen it do well in the sheltered nooks in the flower-garden at Archerfield and Beil, in East Lothian; but I never saw it flourish further north than at Mayfield in Stirlingshire, and in Scotland generally it cannot be put out with certainty. Such plants as Pentstemons, Heliotropes, Pinks, Carnations, Sweet Williams, Phloxes, and many other easily-grown sweet free-flowering plants, are not generally considered "bedding plants;" however, they always find a place in a spare border, and there their beauty is none the less appreciated. *Abutilon Thompsonii* is a showy-foliaged plant for bedding; the leaves are blotched all over with green and golden-yellow. Amongst subtropical plants, *Caladium esculentum* is a noble one, and *Ficus elastica* is invariably useful. Cannas are the best for the inexperienced to start with; they grow freely, and have a very tropical aspect; their foliage is of many different shades. *C. rubra perfecta*, *C. robusta*, *C. discolor floribunda*, and *C. nigricans* are amongst the best. *Yucca aloifolia variegata*, *Y. filamentosa variegata*, *Y. gloriosa*, *Seaforthia elegans*, *Solanum marginatum*, *Dracaena australis*, *D. Draco*, *D. angustifolia*, *Wigandia Wygerii*, *Chamærops Fortuni*, *C. excelsa*, *Latania borbonica*, *Arundo conspicua*, and numerous Aloes, Agaves, &c., are some of the principal plants for making a comparatively hardy and not easily damaged subtropical bed.

J. MUIR.

BLUMENBACHIA (CORONATA) CHUQUITENSIS.

(CAJOPHORA.)

THIS pretty species was introduced by Messrs. Veitch from Peru, through their late collector, Mr. Pearce. It is a dwarf shrubby half-hardy annual, forming handsome tufts about 1½ feet high and

Blumenbachia (Coronaria) Chuquitensis.

about 1 foot through. The flowers, which are borne in great profusion, are of a striking orange-red colour, coronal-shaped, and are about ¾ of an inch deep by 1½ inch in diameter. Its branches and leaves are clothed with hairs, which sting like those of a Nettle. The other species of *Blumenbachia* in cultivation are *B. insignis* and *B. multifida*. *B. insignis* has an angular-branched stem, clothed with hairs, some of which are simply glandular, and others of a stinging character, with opposite palmately-lobed or deeply-pinnatifid foliage, and flowers produced singly from the axils of the upper leaves, on long foot-stalks, which are at first erect, but ultimately drooping. The blossoms of this species are pure white, an inch across, with compressed keeled petals, furnished with a large serrated tooth on each side. *B. multifida* is a plant of much stronger growth, more hispid with stings, and with much larger five-parted leaves, longer two-bracted flower-stalks, and broader obtuse petals. Both species are natives of the southern parts of South America.

PROF. OWEN ON PERMANENCE OF VARIETIES.

It is but justice to the author of the "British Flower Garden," in relation to the "permanence of varieties" mooted in some of the late numbers of THE GARDEN, and to the share taken by insects in their production, in the plant kingdom, to recall attention to the following passage:—"Gladiolus Colvillii—A very splendid hybrid production, that was raised, in 1823, at the Nursery of Mr. Colvill, from seeds of *Gladiolus concolor* that had been fertilised by the pollen of *G. cardinalis*; all the plants that have yet bloomed have been exactly alike, not the slightest variation in them; which confirms our belief that the numbers of species of plants are daily increasing, in the same manner, by natural means, as we increase them by artificial ones; indeed, we cannot see how it can be otherwise, particularly in warm countries, where myriads of insects are continually flitting from flower to flower, and fertilising one species with the pollen of another. By this means of producing hybrid plants in our collections, the flowers may be much improved in beauty and variety, as it is only necessary to consider what two colours to be mixed would cause an intermediate one, surpassing either, with part or all of the spots and marks belonging to both; and plants raised from the seeds of the male plant, if fertilised with its own pollen, will all come as true as any species whatever; not, as has been advanced by some, return by degrees back to one or other of its parents: that is entire nonsense, as anyone who practises raising male plants must soon be convinced of." The results of such experiments, and the conclusions therefrom, are of a higher scientific character and import than the naming of new species from dried plants. In a national *Hortus vivus*, applied to its proper and peculiar aims, these assertions and convictions of Sweet, in 1826, might have been tested experimentally, in such variety and during such tract of time as would have precluded the necessity, more than thirty years after, of a confession of faith, in the "Botany of the Antarctic Voyage," as to the origin of species, based on similar experiments and results made and obtained, elsewhere than at Kew, in private gardens or establishments. I am induced to add this remark by seeing, in your last number, that the national *Hortus siccus*, founded by Sir Joseph Banks, and maintained at the public cost in its proper metropolitan locality, the British Museum, has been deprived of "the collection of dried plants from the banks of Lake Tanganyika, sent home by Lieut. Cameron, which are now in the hands of Dr. Hooker." The keeper of the national collection of dried plants, or botanical department of the British Museum, is relieved of his proper duty, for which he and his assistants receive their salaries from the nation; and the time spent on these dried plants at Kew is so much abstracted from experimental work on the living plants there, which was the prime intention of the wise administrator, Sir Joseph Banks, through whose suggestions and recommendations those botanical gardens were founded and developed by His Majesty King George III.

Sheen Lodge.

RICHARD OWEN.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Protecting Ornamental Beets.—These may be protected by laying a few branches over their tops in autumn, and covering them over with Fern or dry litter. When uncovered in spring, the young leaves will be found to be fresh and to possess the most exquisite colours. The litter should not be laid on them so thickly as to exclude air.—J. T.

The Prostrate Fuchsia (*F. procumbens*).—Dr. Masters showed, at a recent meeting of the scientific committee of the Royal Horticultural Society, on behalf of Kinghorn, a fruit of *Fuchsia procumbens*. The fruit is about half an inch long, obovoid, pink, and covered with a glaucous bloom. It is, therefore, an additional attraction to this interesting species, which is likely to prove a hardy one.

Saxifraga longifolia.—Mr. Muir a few weeks ago stated that he had long edgings of this beautiful plant in the kitchen garden. If it be the true "Queen of Saxifrages," it must indeed be rare and beautiful, but I suspect it is the commoner *S. cotyledon* or *pyramidalis*, which is very generally mis-named *longifolia*. The finest of the section, next to true *longifolia*, is probably the variety named in some botanical gardens *nepalensis*. The strap-shaped leaves are very fine and distinct; it is a free bloomer, and the inflorescence is very striking.—SALMONICEPS.

Origin of Fuchsia Riccartoni (see p. 150).—This originated at Riccarton, the seat of Sir Wm. Gibson Craig, Bart., near Edinburgh, and not at Port Famine, as Mr. Tillery supposes. It was raised from seed by the late Mr. John Young, then gardener at Riccarton, and afterwards for many years gardener at Archerfield. Miss Gibson Craig painted a beautiful flowering-branch of this Fuchsia and presented it to Mr. Young some time before he left Riccarton. I have frequently seen this painting when at Archerfield.—RICHARD NISBET, *Aswarby Park Gardens*.

Hardiness of Liliun giganteum.—Mr. Baxter, curator of the Oxford Botanic Gardens, mentioned to me the other day the case of a plant of this species which had stood in a pot in the open air during two winters without injury. It was then planted out, and the next season was found killed by frost. The ground is very wet at Oxford during winter. Many argue that if a plant will stand being frozen through, as it would be in a pot in the open air, it would be better in the open ground, where it would not be subjected to so low a temperature; but it is evident that the state of the drainage must be taken into account, for it is certain that many plants which are hardy in dry soils will not survive in those that are wet.—J. CROUCHER, *Hammersmith*.

THE INDOOR GARDEN.

DRACÆNAS.

THESE are very common inmates of plant-stoves and green-houses, some of the species requiring the former, others the latter kind of protection. They are all exceedingly attractive, some of them having most beautiful and conspicuous foliage, whilst their habit is such as to render them very useful for all kinds of decoration. They are easily grown, and difficult to kill, although to bring them down to a ragged unsightly condition (as is often seen in plants with their bottom leaves half decayed and the young ones blemished at the points), is a very simple matter. Small plants are generally the most needed and serviceable for room and vase embellishment; and, when used for this purpose, for which they are more and more in demand, they remain a long time in perfection. Larger plants are required frequently for staircase, balcony, and entrance-hall ornamentation. The drooping foliage of some, the upright leaves of others, and the tropical appearance of all, render them splendid objects when used in such places. Some of the most tender species are sometimes placed in the subtropical bed or garden during the summer. This treatment can only be given them in southern counties, and I have often felt sorry to see their dejected appearance in such situations; with the greenhouse kinds it is different. Dracænas should be very extensively cultivated on account of the extreme easiness with which they may be propagated; a single stem, 3 feet in height, will produce three dozen young plants. When any plant becomes uselessly tall or bare of foliage, it should be cut into pieces about an inch long. These may either be put into a bed of soil on a hotbed, or be placed thickly in pans filled with a mixture of peat and silver sand. After watering, the pans should be plunged in a bottom-heat of 85° or 90°; here they should not be allowed to suffer for want of water, although, while plunged, the quantity required is not great. The young plants sometimes come up irregularly, but none should be taken from the pan until they are all fit for removal. As soon as this is the case, the whole panful may be carefully turned out, and potted singly into 3-inch pots, without damaging the young roots. They should again be plunged in the same place, and kept there until they show signs of growing; after that they may be removed, and placed on a shelf or some other hard bottom in the plant stove or propagating pit, where growth should be encouraged until they are ready to shift into larger pots. Hitherto they will have been potted in the same material as that in which they were rooted, but, at this shift, peat, sand, loam, charcoal, and a little decayed Mushroom dung may be introduced with advantage. The mixture must not be too fine, but sufficiently so to admit of a certain amount of all the ingredients being put into a 5-inch pot. This size will grow well-furnished plants until they are 18 inches or 2 feet high; when, if they are wanted of larger dimensions, they must be shifted on—the same mixture being used as that just referred to. After being shifted from the small pots, they generally do not require more root room for one season than is afforded them in the 5-inch pot; so that the following spring is a suitable time for potting on large plants. I have seen some very fine plants grown in 5-inch pots, which is the most convenient size for decorative work. Another means of propagating is found in the root. Large plants form a number of thick leading roots at the base of the stem; at the end of each of these there is an eye. If an old stem be cut up, these eyes should be cut off, and put in together with the other eyes. In shifting well-grown plants into larger pots, these eyes may be taken off during the operation without injuring, or checking the progress of, the plant. In this way, a fresh stock may be raised without even cutting down a large plant; and when only a few are required, I prefer these root growths to any other. Sometimes the tops are put in as cuttings, but I never found these make such good or handsome plants as those from eyes. When propagated, and in growing order, their daily requirements are few. A slight shading is necessary at all times during strong sunshine. They are particularly sensitive to dryness at the root, which often entails the loss of the lower leaves; and the points of the tender young foliage are sometimes allowed to wither through the same cause.

At the Clifton Hall Gardens, Mr. Anderson grows a good many Dracænas in pans about 10 inches in diameter, and 2 inches deep. The young plant is placed in this when quite small, so that the root is easily covered with soil. When this is done, some of the finest kinds of the Selaginellas, and the pretty creeping *Panicum variegatum* are planted on the surface of the pans, a method which produces a remarkably pleasing effect, as the creepers form a cushion of green and white underneath the drooping high-coloured leaves of the Dracæna. The following I consider are among the best to grow either singly or collectively:

D. ferrea versicolor (terminalis).—This is one of the oldest, best known, and most beautiful. It was introduced into this country, from the East Indies, in 1820. The leaves grow from 1 to 2 feet in length, and 4 and 5 inches in width; they are of a dark green colour, richly and profusely shaded with brilliant scarlet; the young leaves, and the entire upper part of the plant are sometimes wholly scarlet. It succeeds best in an exotic stove.

D. Macleayi.—One of the best of the dark-leaved kinds; it does not grow rapidly, but is very robust. The leaves are generally from 18 to 24 inches long, and are of a very deep brown hue, with a metallic polish. It contrasts strikingly with the former in colour, but is of the same graceful habit.

D. Chelsoni.—This makes a fine plant. The leaves are very large; the ground colour is a bronze-green edged with crimson.

D. Cooperi.—This somewhat resembles the first described, but is, if possible, more beautiful in colour and more graceful in habit. It is moderately hardy, and does fairly in the greenhouse during the summer months.

D. Guilfoylei.—A magnificent species, with long narrow leaves beautifully variegated and striped with bright rosy-pink, white, green, and red; the leaf-stalk is also variegated. Being a native of the South Sea Islands, it is somewhat tender, but, like the rest, easily grown.

D. gracilis.—This is an elegant little plant; the leaves are only about 1 inch in breadth, 12 inches in length, and incline nearer to the horizontal line than those of other kinds. The main colour is bright green, margined with purple.

D. Dennisoni.—Another elegant species, of the deep bronze type; leaves, from 12 to 15 inches long; habit, compact; other characters good.

D. regina.—This is different from any of the preceding, and a fine variety; leaves, erect, centre green, edged with creamy white; sometimes the upper half is quite white, which gives a speckled appearance to any collection with which these plants may be intermixed.

D. umbraculifera.—This is quite different from any of the above; it grows several feet high; the leaves are generally about 3 feet long and 1 inch broad, and of a rich glossy green colour; at the top they stand straight out, but the older ones at the bottom droop. The plant, when large, forms a conspicuous object anywhere; it grows rapidly.

D. magnifica.—Leaves, about 8 inches in width, and as much again in length. When young the leaves are pink in colour; when old they are of a purple-bronze shade.

D. Draco, D. australis, and D. atro-sanguinea, are nearly hardy, and useful for conservatory decoration. I may further state that greenfly is sometimes troublesome on the young leaves; fumigation is the remedy for this, and a sponging now and then keeps the foliage clear of dust and insects.

J. MUIR.

THE BEST FRANCISCEAS.

Franciscea confertiflora.—This is one of the most useful of all stove plants. A warm greenhouse or intermediate-house will suit it, but the temperature must not be allowed to fall below 45° Fahr., or injurious effects will follow. It is useful as a decorative plant, and for exhibition it ranks as one of the best, its habit being good and its colour of the dark purple which is so much needed among plants in bloom or in the exhibition tents. When bloomed under proper treatment the flowers are very dark, but, if opened in heat, they become much lighter in colour. The greenhouse is the place in which to bloom them, and, with plenty of light and air, colour and substance will be obtained, and the plant rendered more

robust and better capable of bearing removal to exhibitions. If the plant be well tied and treated as recommended, it may be used more than once or twice. After its return from any exhibition, examine the plant carefully, and pick out the stale blooms, placing the plant in the house again; in five or six days it will be ready for use again with a crop of bloom as good as before. After the blooming season is over, and if the plant be small, and you are desirous of increasing its size, encourage its growth, stopping any shoots that may be too vigorous, in order to throw more strength into the smaller and weaker growths, and, towards the fall of the year, when the plant has done its work, it will begin to set its bloom for the following season.

Franciscea Lindeni.—This variety has only recently been introduced, and is therefore comparatively unknown. It is my belief, however, that when more widely grown it will be appreciated on account of its being easy to manage. Its character is very different from that of *confertiflora*, which sets its bloom in the autumn, whilst *Lindeni* produces its bloom on the growth it makes in spring. After it has finished blooming, it can be treated as *confertiflora*, if an increase in size is found desirable. When tied and put into shape, take off all the points, or rather stop them, and then you will have several breaks instead of one when the plant is started for blooming. It will stand in a warm greenhouse throughout the winter, till six or seven weeks before it is wanted; place it in the intermediate-house till the flowers are nearly opened, and then harden off in the greenhouse; it will thus obtain colour, and be fitted for exhibition.

Franciscea calycina is distinct as regards habit. The flowers are large, and, though useful for home decoration, it is not so well suited for exhibition purposes, as the flowers bruise easily in carriage; anyone growing *Francisceas* for exhibition alone may, therefore, dispense with this variety, although it is well worth growing for other purposes.

Franciscea eximea.—This is one of the hardiest of all the *Francisceas*. It will stand through the winter in a cold greenhouse, where it will retain its leaves till spring, and before blooming it will be clothed with new foliage, so that the treatment for *Lindeni* will suit *eximea*, which, like the former, flowers on the young wood it makes in the spring. There are other kinds, but those mentioned are the most valuable; and, well grown and bloomed, will well repay anyone for their trouble. I have found them thrive best when potted in equal parts of good loam, peat, and sand, with the assistance, in the growing season, of clear liquid manure, or one or two dressings of Standen's manure. When the plants get established, and of a reasonable size, they will go on for years without shifting, but their wants—of which the grower will be the best judge, from having them always under his care—must be attended to.

J. W.

Hardy Plants under Glass.—I have read with interest the letter of "D." in your columns (see p. 115). I am in the habit of doing much as he does. One tires of *Cinerarias* and *Primulas* in a greenhouse, and I do not find it so easy at all times to have variety there; but hardy plants, which have been taken from the open ground, are a great help, and in many cases they can be put in the border again without receiving any injury. Another advantage of this method is, that by subjecting specimens of the same sort of

plant to different influences you very greatly prolong its blooming time. Thus I have now *Anemone apennina*, *Dielytra spectabilis*, &c., in full flower in a cool greenhouse, and when they go off there, others of the same kind will be fast coming on in the garden. I think, however, that "D." might add to his list several very desirable plants, such as *Dielytra spectabilis* beyond all others; two or three sorts of *Spiræa*, *Trillium grandiflorum*, *Schisostylis coccinea*, *Stokesia Cyanea*, &c. I wish that I knew the names of some more good things for this purpose, for I find that while some respond to it easily others resent the treatment altogether.—H. EWBANK, *St. John's, Ryde*.

COCHLIOSTEMA ODORATISSIMA.

THIS plant was introduced into Europe a long time ago, but it is not with certainty known whence it came or who first discovered it. Everything, however, points to the fact that, like its beautiful congener *Cochliostema Jacobiana*, it comes from tropical America, most likely from Brazil. It was originally cultivated under the name of *Tradescantia odoratissima*, but was re-named by M. Charles Lemaire, under the impression that it had nothing whatever in common with the genus *Tradescantia*. It is an herbaceous plant, the leaves of which are long and graceful, pale on the upper surface, with undulated edges ornamented with red. The flower is composed of

Cochliostema odoratissima.

three canicular sepals of a yellowish-green at the base, becoming reddish towards the extremities, and three large oval obtuse petals, edged with blue, with a larger white blotch at the base. The most interesting part of the flower from a physiological point of view is the stamen, which is composed of a short filament dilated so as to form a conical pouch, woolly at the base, acuminate at the upper extremity, and enclosing two organs which somewhat resemble the screw of a wine-press, and taper off at the two extremities. The *Cochliostema odoratissima* (says the "Revue Horticole") enjoys a damp warm border, an open and turfy rather than a sandy soil, with which may be mixed a little *Sphagnum*, the whole being well drained. Frequent sprinklings and waterings are necessary during its

growth, which must be withheld during its season of rest. It is propagated by means of offsets.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Fuchsia Rose of Castile.—This fine variety makes a most showy pillar and rafter plant in a greenhouse or cold conservatory. I have it here trained to an ornamental wire trellis of pillar, and it has now got to the height of 12 feet. Being spurred in at pruning time, it is one sheet of bloom from bottom to top all through the summer and autumn months.—W. TILLEY, *Welbeck*.

Continuous-blooming Indoor Roses (see p. 168).—No Rose will bloom always; but some will bloom longer and oftener than others, as, for instance, kinds belonging to the Tea and Noisette sections. I should recommend your correspondent to get *Gloire de Dijon*, *Madame Falcot*, *Madame Maurin*, and *Vicomtesse de Cazes*. For a Hybrid Perpetual, none beats *Jules Margottin*.—N. H. P.

Chrysanthemums to Bloom in Large Quantities.—I want a large quantity of cut blooms of this favourite autumnal flower, and I am thinking of planting out an abundance of cuttings of it in the reserve garden, and taking the plants up in the autumn and putting them pretty thickly on the floor of the conservatory, merely filling in amongst the roots with soil and then watering. Will anyone say whether or not I may trust to this plan for yielding me what I require?—N. H. P.

Virgin Cork for Covering Garden Tubs.—Round or square tubs for garden purposes, especially when used in houses, are not satisfactory; on the contrary, they often look unsightly in themselves and spoil the effect of the plants. At the Alexandra Palace, Mr. McKenzie has got rid of this objectionable feature by covering them with virgin Cork, and the effect is extremely pleasing. Round the rims and bottoms of the tubs are single bands of cable rope, which impart to them a finished appearance. Small tubs and baskets may be made entirely of Cork, but for large plants it is not strong enough.—J. CROUCHER.

GARDENING FOR THE WEEK.

Flower Garden and Pleasure Grounds.

CONTINUE to increase the stock of various kinds of bedding plants in such quantities as may be required. Beds formed on Grass or gravel are not unfrequently margined by an edging, which may consist of sundry materials; but such as are formed of glass are better than any live edgings for flower beds, as they tend to preserve their form, and may generally be allowed to remain undisturbed for several years. In all cases, however, wherein tiles are not used, the turf round the beds should be carefully cut into proper shape by means of a sharp knife or edging iron. But, as flower beds generally form a geometric group of more or less intricacy, each bed forming a component and necessary part of the whole, it is expedient, in performing this operation, to ascertain the exact centres from which the various curves forming the beds are described, otherwise the beds will soon deviate very considerably from their original shape should the operation of edging them be repeatedly performed by the aid of the eye only. The rough sketch of the garden, however, which I have often recommended to be used as a memorandum for the names and quantities of plants required for the beds, if correctly drawn, could also be made to materially assist in this matter, by having the various centres distinctly marked upon it. In planting, care must be taken to avoid a too free use of the primary colours, such as those produced by the scarlet *Pelargonium*, the yellow *Calceolaria*, &c.; and in nearly all flower gardens a judicious use may with advantage be made of succulents, and other ornamental-foliaged plants of various kinds. Many succulents which are found to be so useful for this purpose are quite hardy, such as the *Sempervivum californicum*, *Sedums* of various sorts, &c.; while the *Echeveria secunda glauca*, on account of its soft neutral-tinted foliage and compact habit of growth as a marginal plant, requires only the protection of a frame or cold pit, and should be kept very dry during the winter months. Small plants of this *Echeveria* should now be encouraged to grow; while larger plants of it should be kept as cool and quiet as possible, in order to have them all, as nearly as possible, of a uniform size when the planting-out season has arrived. Sub-tropical plants of various kinds, intended to be increased by means of division and cuttings, should now be placed in strong heat, in order that their propagation may be proceeded with as rapidly as possible, so as to have them sufficiently strong when turned out to produce an immediate effect early in June, which is as early as this can be done with safety. If it be desired to raise a stock of the various kinds of *Cannas* and similar plants from seeds, the latter ought to be sown immediately if the plants are expected to be effective during the first season. Young plants of the *Musa Ensete* will probably form very effective objects in the sub-tropical garden, but its seeds should be sown at once in order to get the plants of sufficient size to turn out. The middle or the end of March, however, will be sufficiently early to sow seeds of many of the quick and strong-growing annual plants which are so effective in this style of planting, such as the various *Castor Oil* plants, *Maize*, and its variegated or striped variety, *Beet*, *Solanums*, *Amarantuses*, &c. The various varieties of *Gladioli* for early flowering should be planted now in soil which has been liberally dressed with well-rotted hotbed or cow manure, and which has been deeply dug or trenched. They may be planted in beds, with the bulbs placed at a distance of 10 or 12 inches from each other, and planted about 3 inches deep; or they may be planted in clumps, consisting each of a few bulbs, on the Rose border, between standard or other Roses, or with very good effect in front of *Rhododendrons*—the soil prepared for American plants being generally found to suit *Gladioli* well. The following beautiful and interesting plants are also found to succeed admirably when planted in a similar situation, all of which should be planted about the present time, viz.: *Ixias*, *Sparaxis*, *Tritonias*, *Watsonias*, *Nerines*, *Zephyranthes*, &c., the bulbs of which may all be planted about the same depth, as has been recommended in the case of the *Gladiolus*. The stakes and ties of standards and other plants requiring support should be examined, and replaced where necessary. The margins of shrubbery borders will now be gay with the *Snowdrop*, *Crocuses*, *Primroses*, *Violets*, &c. Much of the charming effect, however, which these welcome harbingers of early spring produce will be lost if neatness and good order do not characterise all their surroundings.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Roses.

Rose Forcing and Roses for Forcing Through the Winter Months.—This winter has been a severe one for Rose forcing, for we have had more rain and less sunshine than usual. A few remarks, therefore, upon the varieties that have succeeded best may be of advantage to those who desire to go thoroughly into Rose forcing. I have found it to my advantage to have a small house set

apart expressly for forcing Roses, and have thus succeeded for two seasons in cutting Roses all the year round, having obtained all the best varieties of pot Roses and nearly all the Tea varieties that are useful for pot culture. The first matter that, in order to ensure success, must be thoroughly attended to is freedom from greenfly, mildew, or caterpillar, and the glass should be kept clean during the winter months, so as to make the house as light as possible. These pests are easily overcome by remedies given in former numbers of THE GARDEN. November and the early part of December, in my experience of Rose forcing or growing, is the worst time for producing flowers, but by carefully housing the late summer-pruned plants there are many varieties that will be found to have enough buds to keep up a succession of flowers till the early forced varieties begin to come into flower about the end of December. This cannot be done with a few plants, but it necessitates the possession of a good stock of pot Roses. In December, for Christmas:—*Maréchal Niel*, *Lamarque*, *Goubault*, *Isabella Sprunt*, *Gloire de Dijon*, *Sofrano*. The flowers of these were all excellent for the time of year, with *Duke of Edinburgh* and a few other hybrid-perpetual flowers, but they drop as soon as cut, although for one evening they last well. In January for New Year's Day and through the month *Maréchal Niel*, *Isabella Sprunt*, *Goubault*, *Gloire de Dijon*, *Sofrano*, *Madame Falcot*, *President*, *alba rosea*, *Belle Lyonnaise*, *Devoniensis*, *Lamarque*, *H. P. Centifolia rosea*, *Beauty of Waltham*, *Duke of Edinburgh*, *Charles Lefèvre*. The above have answered the best; they have flowered as well as could be expected and have fine blooms. For February the foregoing kinds must be added to *Souvenir d'un Ami*, *General Jacqueminot*, *Victor Verdier*, *Boule de Neige*, *Elie Morel*, *Dupuy Jamain*, *Exposition de Brie*, *Madame Julie Doran*, *Princess Louise*, *La France*, *Comte de Nanteuil*, and *Catherine Mermet*. These varieties I have found to force well, and I must state that *Maréchal Niel* is without exception the easiest Rose to force, and the freest flowerer through the winter. No forcing house ought to be without one of these plants. The flower of *Maréchal Niel* and *Devoniensis* stand best after being cut. *Goubault*, *Isabella Sprunt*, *Madame Falcot*, *Sofrano*, and *General Jacqueminot*, should always be cut in the bud, for, if allowed to expand, the flowers are useless for packing, and very soon drop. *Alba rosea*, *Lamarque*, *Duke of Edinburgh*, *La France*, *Charles Lefèvre*, and *Boule de Neige* are excellent varieties, both in bud and open, and are about the best and foremost flowering varieties for forcing; as perpetual flowerers *Maréchal Niel* and *Goubault* bloom all the year round. Most of the other fine flowered varieties will now be coming into bloom. I have only enumerated those I have found do well for very early work.—H. G.

Floral Table Ornaments.

Ornamental stands for growing flowers and plants can be easily constructed in the following manner. Take an ordinary 10 or 12-inch seed pan, and have it painted green outside; cover the bottom of the pan with broken crocks, and fill it in with soil to half its depth, as though about to sow seed. Then fit it up with whatever plants and flowers may be desired; *Adiantum cuneatum*, or any other light-growing Fern in the centre, with a wreath formed round it of *Snowdrops*, has a very pleasing effect; or, for this outside ring, dwarf, white, and scarlet Tulips are also well adapted. Those who may not care for a Fern in the centre, can substitute a group of three Hyacinths, or a clump of Lily of the Valley; either white Hyacinths, or the latter with bright blue dwarf *Scillas* round the outer margin, look well. The fitting up of these little stands is, however, quite a matter of taste, as, what might please some, others would not care for. However, presuming one to have had the flowers placed in their proper position, they should be packed in with fresh wood Moss, to keep them steady and also to cover the soil, which, if left exposed, looks unsightly. Fresh-looking Moss should be chosen, and the effect of the flowers growing up, as it were, through it, is very pleasing. If the appearance of the outside of the pan be objected to, it can be hidden with an expanding cover similar to those employed for concealing pots; if this cover be of gilt rustic work, the dark green back ground throws it up well. These little pans can also be purchased, made of rustic terra cotta (like those covered with a bell glass, which form Fern cases), or of virgin cork. The two last are most expensive, and do not look as well as the ordinary pan, if the latter be covered with a case such as I have described. These little stands look well in the drawing-room, and form tasteful ornaments for the centre of a small dinner table for every day use. If they are used for the latter purpose, *Scillas* should be avoided, as they lose their pretty bright blue shade when subjected to artificial light. They are, however, well suited for the breakfast table.—A. HASSARD, *Upper Norwood*.

Indoor Fruit Department.

Vines.—When all the soil intended for making Vine borders is chopped up, one barrow load of lime rubbish, and the same quantity of roughly ground bones, should be added to every ten barrow loads

of it, and the whole should be turned over two or three times until all the materials are well mixed together. Charcoal may be used instead of the lime rubbish, where the latter cannot be conveniently obtained. They both serve the same end, viz., keeping the soil open; and where it is naturally of a very open character, they may be dispensed with altogether. The bones should not be overlooked. I dislike horse droppings in Vine borders, as they have a tendency to produce fungi, and other kinds of soft manure are not lasting. Vines to which such manures are given often do remarkably well for a year or two, and then suddenly begin to go back. Young Vines planted last season, and which have been started this year with the intention of getting them in early, should now be pushing vigorously, and require, at first some care in training. When they are planted $2\frac{1}{2}$ feet apart, only one rod should be taken from each root. If a foot or two wider than this, two may be taken. All the shoots should be rubbed off, except the two from which the canes to be retained are to spring. These should be trained at equal distances one from the other, and should be brought away from the bottom in the form of the letter V. All tendrils and lateral growths should be kept within bounds, in order that the leader may make as fine a shoot as possible, as the lower part of it will have to bear a crop next year.

Pines.—Select the first mild day for re-potting and overhauling the stock of these. Soil and pots should be in readiness before disturbing a single plant, in order that no check may be given through exposure. Large fresh well-rooted suckers may be shifted into their fruiting pots at once, while small plants, indifferently rooted, should be re-potted into small pots and grown on for six weeks or two months before being placed in large pots. Smooth-leaved Cayennes, Charlotte Rothschilds, Providences, and other strong-growing varieties, should be placed in fruiting pots 12 inches in diameter across the mouth, but pots 2 inches less will be large enough for Queens. When potted, they should be well and firmly plunged in the beds in which they are intended to be grown throughout the summer. Previous to plunging them, the old fermenting material should be mixed with a liberal addition of new tan, and the glass and wood-work should be well scrubbed with a brush and soft-soap and water. Two feet apart in the row will be room enough for Queens, and 6 inches more for the others. In plunging, the pots should be placed level, in order that they may hold water. When all are plunged, a string supported by stakes should be put along the edge of the bed next the pathway to prevent the leaves from coming in contact with passers by. If the plants are tied up, when untied, every leaf should occupy its former position; 80° will be sufficient bottom-heat with which to start, and it should not be allowed to rise above 5° more. Re-plunge those unfit for fruiting in the bed from which they were taken.—J. MUIR.

Hardy Fruit.

The cold we are now experiencing has given a salutary check to the swelling of all kinds of fruit buds; no time, however, should be lost in preparing protection for wall and other fruit trees. If expensive coverings of glass, canvas, or netting are not to be had, one or other of the methods of protection recommended in a former Calendar should be adopted, and labour or trouble must not be taken into consideration if a crop of fruit can be saved by these means. On bright sunny days the coverings should remain down, in order that the opening of the blossom may be retarded as long as possible, for, as the season advances, there will be a greater likelihood of favourable weather at the "setting" period, which is always the most critical. Presuming that planting has been completed, each tree requiring it should be staked and tied; tar-twine is the best for this purpose, and a bunch of hay, straw, or moss should be placed between the stake and the tree to prevent injury, and, if it has not previously been done, spread over the roots a thick layer of decayed leaves or litter, as drying winds may soon be expected, and mulchings of this kind neutralise their effects. Stake and tie into form espaliers and pyramids, and see that all are correctly labelled. If American blight or scale be troublesome, paint over the trees with a strong solution of soft soap, sulphur, soot, and lime. As a rule, this should be done before the buds have begun to swell; but it may yet be done with safety. Cuttings of Gooseberries and Currants may now be put in. Select the straightest cuttings, and let them be at least 12 inches long, and plant in lines 18 inches asunder, and 3 or 4 inches apart in the lines. So soon as started, pick out all the eyes or buds, except a couple at the top, which will give clean stems to the future trees. The grafting season is now fast approaching, and all scions for the purpose should be prepared and heeled in, for it is necessary to successful grafting that the scion should be later than the stock, and this can only be managed by securing the grafts before the sap begins to rise. There being now so many good varieties of all kinds of fruit, doubtful or second-rate kinds should not be tolerated, but the trees headed down and grafted. Clay for grafting should be got ready by

tempering it well, and by working in with it a portion of horse-droppings to ensure adhesiveness.—W. WILDSMITH, *Heckfield*.

Kitchen Garden.

A heavy fall of snow, accompanied by rather severe frost, has for the present suspended operations out-of-doors, so far, at least, as regards planting or sowing; but advantage might be taken of such weather to prepare materials for making up or renewing hotbeds, making reed or straw mats or screens, which are so neat and economical for protecting early crops in cold weather, or for laying over seed beds in early spring instead of using loose straw, which, in a private garden, looks untidy. Such screens are also equally useful later on in the season for keeping the earth cool, and encouraging the rapid germination of successional crops of Radishes, &c., in the hot weather. When the weather breaks and the land becomes dry enough for resuming operations, the sooner the spring-sown crop of Onions is got in the better, and especially is this necessary in the case of light soils, or where the crops suffer from drought in dry seasons, so as to get the young plants well advanced in growth early in the season. To obtain fine bulbs a long growing period is essential, and to obtain this object an early start is advisable. Screens should be more used in this way than they are, as, unfortunately, few gardens are so well provided with water as they ought to be, or, with what is equally necessary, proper machinery for its economical distribution. In dealing, however, with heavy retentive land, we must wait till the surface is dry. Assuming that the quarter intended for the main crop of Onions was well manured and worked up deeply during the autumn or early in winter, just previous to preparing it for sowing wheel on to it sufficient thoroughly-decayed manure, to which, if it can be had, charcoal dust, burnt earth, charred refuse, or any similar material may be added, so as to form a surface dressing about an inch or so in depth, rake it well about, so as to partially mix it with the surface soil, raking all smoothly at the finish, and removing all rough pieces and stones. I sow in drills from 9 inches to 1 foot apart, because of the facilities such a plan gives for hoeing and cleaning; otherwise equally good Onions may be had by sowing broadcast on 4-foot beds, if thinned early. In any case the ground should be made firm either by means of treading or rolling, and do not bury the seeds too deeply. The Brown Globe is one of the best Onions for keeping purposes, and the White Spanish or Nuneham Park for general early use. I have already said that, as far as possible, all things should be sown in drills, and we have here a very simple form of drill that any carpenter can make for a very small sum. The head and handle are formed like those of a common wooden hay rake, only much stronger and heavier; the head is made of Oak, 2 feet 4 inches long, $2\frac{1}{2}$ inches deep, and 2 inches wide, in which are inserted three triangular drills or teeth about 1 foot apart; the teeth are 3 inches wide and about the same in depth, and, of course, taper off to a point. In drilling a piece of ground, all that is required is to set the line properly in the first instance, and in drawing the implement across the quarter the first time, the end will run parallel with the line and close to it; afterwards one tooth will run along the last drill made, and in that way all will be kept straight and true. Laxton's Supreme, Hundred-fold, or any of the improved forms of Champion of England Peas, may be sown now, as may also William the First or any other esteemed dwarf early kind. It often happens that Peas sown in March will come in within five or six days of those sown in January, but in most places those few days gained are appreciated. In heavy soils where Parsley is a long time in vegetating sow some now in light soil in boxes, and transplant in April. I always transplant a part of my crop, and the transplanted is invariably the most curled, and best for garnishing. Make a small sowing of the scarlet Intermediate Carrot to come in after the Early Horn; but the main sowing of Carrots should in most places be delayed till the first week in April. Divide and transplant Chives about 9 inches apart. They are used in some places for flavouring Salads, &c. Sow strap-leaved Turnips on an east border where the soil is rich, and where the surface has been heavily dressed with charred material from the rubbish heap, a fertiliser which will ensure that free and rapid growth which is essential to mild flavour. The crop would be forwarded if a foot or so of hot manure could be had, so as to give a slight bottom-heat; but, as the season is now rapidly advancing, this is not absolutely necessary. Sow Chervil on a south border to come on early. Basil and Marjoram sown in heat should be pricked off when large enough, and pushed forward under glass for early use.—E. HOBDAV, *Ramsey Abbey*.

Deep-digging Light Land.—I am not overdone with labour power, and to get my land deeply dug without the extra labour and time of double digging, I get my men to dig with drainers' tools. These tools have blades 18 to 20 inches long, are spoon-shaped, and taper to the end, so that they leave the bottom ground as open as a 3 or 4-tined fork would do. The effect on the crops is remarkable.—N. H. P.

FORMING LAKES AND PONDS.

WATER seeks its bed in the lowest ground, which should always be made choice of for the formation of a lake; but, when the lowest ground cannot be made available, so as to bring the water into view from the house or the pleasure ground, and a higher level must unavoidably be taken, the view beyond must be stopped by planting. The designer, therefore, after he has fixed the sites, and taken such levels as may be considered most suitable for the purpose, will at once see the necessity of judicious planting about the lower end of the lake, so as to fill up, and shut out, as much as possible, the appearance of the valley below, especially in the vicinity of the lake. In most cases this will give the appearance, in a great degree, of water resting on a natural flat. In lining out lakes of large size, bold prominences and deep bays must be produced rather than tame, zigzag, or small indentations. In well-kept grounds, lakes or ponds must be characterised by the same bold curves; but the margins should be kept neat, with smooth Grass to the water's edge, rather than consist of deep, earthy, and broken banks. Yet gentle and grassy swells, rising immediately from the water, are important acquisitions; and some portions of the margins may be fringed with interesting and suitable plants. Islands are indispensable in lakes of considerable dimensions; they not only add greatly to the variety and interest of such pieces of water, but are of importance in assisting to conceal their real extent. The greatest depth of water in a lake should never, if possible, exceed 5 feet, in order to render it safe from accident during sailing excursions and winter amusements on the ice. This depth is, moreover, quite sufficient for fish, proper provision being made for their retreat, in severe weather, about the islands and in the deepest parts of the water. These retreats may be composed of roots of trees, or stones, reared together; or stones, sunk at intervals, with a slate across them. The water should also be clear, and not stagnant, and kept free from rubbish. Having decided upon the site, we must next determine the levels. If the fall of the ground is considerable, it will generally be better to lower the highest side rather than raise the head or dam too much. We would rather lose sight of a portion of the water nearest the point of view by the rising ground, than have a prodigious embankment; this would, in almost every case, not only be found to work better but please the eye more, especially with a judicious sloping of the higher ground, and with proper breaks in planting. The levels having been taken, a better notion of the form of the water will be ascertained. But in staking out in undulating ground, advantage must be taken of the lowest parts of the ground to give breadth or expanse to the water, and variety of form in its outline. Otherwise, cutting down the rising knolls would not only cause additional expense, but greatly lessen the variety of surface, which we ought ever to study to preserve. Where a bridge is to be introduced, two of these prominences should be brought near enough together to afford a natural site for that purpose; where it is not required for convenience sake, but only for effect, one end of it may rest on an island, in which case the latter must be sufficiently large to make a bridge seem useful for landing upon it. In shaping the embankment or head, much will depend upon its depth and extent. If the valley, where the head is formed, is narrow, its construction will not be difficult; but should it be wide, great caution will be required, not only for security against the pressure of water, but that its outline may be as natural as circumstances will allow. This will generally be best managed, and the pressure of water borne, by forming a large and bold promontory to shoot out a considerable extent into the lake, of sufficient surface to allow of an outlet for the water, and room for planting on each side of it, without interfering with the puddle. This will be most properly effected by raising the ground a little above the general level (with the exception of the margin close to the water), and so providing depth of soil for the roots to work in. Further, in forming the embankment, or head of a pond or lake, it should slope considerably under the water. This gives strength to the dam, inasmuch as the water bears upon the slope, and is not so liable to burst the bank as if the latter were more perpendicular. An equal, or rather greater, slope will be required on the contrary side of the bank; and it is indispensable that a

firm wall should be built where the water passes over, to prevent its being washed down. But if an interesting fall is to be formed (which certainly ought to be if water is plentiful, and if a walk can with propriety pass near it), it should be built in a natural firm form, with rugged massive stones.

Islands.

One island near the head will generally be necessary; and if sufficiently large and well managed, will be better than more. This should be placed 10 or 20 yards from the outlet, and perhaps should be the widest across the pond parallel with the dam, letting the side next the outlet of the water form a broken or irregular concave, in order to harmonise with the convex or promontory stretching into the water. Then, a little above the island, the margin or outline of both sides of the pond should be made to project into the water, so that, conjointly with the island, the eye may be prevented from discerning the end or outlet of water, thereby deceiving the mind as to its extent. But, in order to effect this properly, bushes and trees must be planted on the island and on the sides of the lake. In lakes of considerable extent groups of islands would be effective, and ought to be introduced, in preference to their being scattered singly all over the water. They must, further, be placed not as if by design, but rather to appear in connection with some of the smaller or moderate-sized promontories, and as if the water, from time to time, had severed them from the adjoining projection of the shore. Whatever may be the number of islands forming a group, care should be taken to have the largest of them about the centre. For instance; on all the sides but that next the shore, the smaller islands will appear most in character outermost, and the distance from one another must vary considerably. These islands may be from 5 to 30 yards or more from the side of the water, according to its extent; but must be sufficiently far from the middle not to appear central. In a lake of 50 or 100 acres several groups, composed of three, four, or five, of different shapes, may be formed; and one or two of these may be of considerable extent—say, from a quarter of an acre to one or two acres. Although formality should be avoided in placing islands, yet the appearance on both sides the lake should, in some measure, be equalised, leaving the widest portion of water about the middle, but still naturally broken or varied with the islands. Were there a large island and numerous small ones on one side of the lake only, from some points of view the water would appear out of balance, leaving the eye dissatisfied. This effect must be guarded against. The prevention of danger must be observed in the formation of water. Such danger too frequently arises from the usual way of forming ponds or lakes, and the means by which it should be averted are these:—First, it is quite unnecessary to have deep water close to the margin; as there is the same breadth or extent of water, and certainly an equally good effect is produced when the water is shallow as when it is of considerable depth. It is, therefore, of the first importance that a shelf or platform, 4 or 5 feet broad, should be formed all round the margin of the lake, admitting only of water resting upon it to the depth of from 6 to 9 inches, so that should even an infant fall in its life would scarcely be in danger. This platform may fall from the margin towards the water to the extent of 4 or 5 feet, at the rate of about an inch in the foot; the slope from that point must be much more rapid until it ends in the deepest part. If white pebbles, or pebbles of any kind, or even small stones mixed with sand, could be spread all over the shelf, it would add much to the clearness of the water and the general beauty of its edge. All the margin in natural and varied surface should not appear smooth and even, but Nature should be studiously imitated; and this will be greatly promoted by allowing at intervals steep or deep earthy margins to appear, and large stones, and roots or stumps of trees, to present themselves in masses and groups. Of course the margins in polished or kept grounds must assume a varied appearance, without being rugged. In all ponds or lakes it is necessary to use puddle of clay in places where embankments are made to dam the water, in order to prevent leakage. In such parts the puddle-dykes should be made in the ledge or shelf above-named, where, I think, it would be the least liable to be injured by the roots of trees and bushes. The bottom

ORNAMENTAL WATER

of the lake, also, when the materials are not naturally retentive, will require puddling, especially about and under the dam, or other raised parts.

Lake Vegetation.

Trees and bushes are indispensable embellishments to water. They are important for concealing its real extent, besides producing light and shade. In planting near water we must not interrupt the best and most lengthened view of it, as seen from the house and the principal parts of the park or pleasure ground; neither must we entirely shut out from view the whole of the ends or boundaries of the outward prominences, or some of those parts which project into the water. At the same time caution must be used not only to prevent the eye from catching the various bends of the outline of water from any one point of view (which would be bad), but also so as to afford variety in the grouping of the trees and shrubs; indeed, the whole planting must be so effected as to leave the extent of the water undetected, and even unimagined, from any one position. The following may be named as suitable for planting in the neighbourhood of water. Those to be employed as low growths in dressed grounds should consist of common Heath, Ferns, double Ayrshire Roses, Sweet Gale, English Juniper, dwarf spreading Willow, Andromeda polifolia, Ledum palustre, and others. The Alder, kept low by occasional cutting, makes a fine fringe, and forms a strong barrier for the margins of water when the current is liable to wash away its banks. The common Whitethorn, Bramble, hedge Rose, red Dogwood, Honeysuckle, and Blackthorn, afford proper marginal decoration for water in natural scenery. Trees suitable for dressed grounds may be of various kinds. Those best adapted for positions nearest the water, where the ground is liable to be moist, must consist of the common Alder, various kinds of Willow (including the Weeping and Rosemary-leaved Willow), *Alnus cordifolia*, Norway Spruce, deciduous Cypress, and Hemlock Spruce. Such plants are also quite proper for the islands; but in order that the roots may not lodge too much in the water, the parts of the islands to be planted should be raised irregularly, or in a natural manner, with stones, roots, sods, &c., mixed with suitable soil, a few feet higher than the level of the water. The five last-named kinds of trees are most appropriate for beautifying water in well-kept grounds. Amongst the larger trees employed, not exactly fringing the margin, but at a moderate distance from the water, the Wych Elm is the most elegant, and should always be planted in extensive places; its elegant massive twigs and pendent branches entitle it, above all other large trees, to this distinction. Nevertheless, the English Elm, Lime, Beech, Weeping Birch, and Larch, would be appropriate. Every kind of Poplar should be excluded, except, indeed, the Lombardy, of which two or three may be planted so as to rise out of the midst of masses of other trees. In planting, room should be allowed for walking near the water's edge; sometimes close to it, and at other times with a bush or group of shrubs interposing. Swans, by all means, must be introduced, as well as other water fowls.

Effect of the Winter in the Edinburgh Botanic Gardens.

—Mr. M'Nab states that some plants in the Edinburgh Botanic Garden have suffered considerably from the effects of the past winter. A few points of some of the Cupressineæ are observed to be a little browned, particularly in low situations. The leaves of the Golden Queen Holly are also much discoloured. The green Hollies, particularly the tree forms, have parted with a large quantity of their leaves. The *Phormium tenax* or New Zealand Flax, as well as the *Cordyline angustifolia*, have suffered severely. Many of the latter plants have stood unprotected on the rock garden during the last five years, some having attained the height of 6 feet. During December, 1870, the frost was so severe that several of the *Cordylines* at that time were killed to the ground, but they again pushed up from the lower portion of the stem, and afterwards became fine plants; hopes are therefore entertained that the injured specimens will all break out again, the plants being considerably stronger than they were when last damaged.

Terrestrial Radiation.—Professor Dyer made the following communication the other day to the Scientific Committee of the Royal Horticultural Society, basing his remarks upon the observations of Mr. Buchan:—"The effects of terrestrial radiation are at

the maximum when the air is calm and very dry, and its temperature rather low. If, however, the cold air produced through the influence of terrestrial radiation be allowed to accumulate close to the ground, no small amount of damage may be done by a comparatively slight frost. On sloping ground such accumulation of cold air cannot go on, because cold air being heavier than air which is warmer, as soon as the air in immediate contact with sloping ground is cooled, it flows down to a lower level, just as water would do, and its place is taken by the warmer current of air immediately over the downward-flowing cold current of air. In this way a higher night temperature is maintained in situations where the ground slopes down to lower levels, and accordingly such situations should be chosen for those plants which, at any stage of their growth, are peculiarly liable to be injured by frost. If the air be not calm, but a wind—even a slight wind—be blowing, the different layers of air are thereby mixed; and thus the air, cooled by contact with the cold ground, is not suffered to rest on the ground, but is mixed with the air above it, and the temperature is thus prevented from falling so low as it otherwise would."

DRAIN GRATINGS FOR GRAVEL WALKS.

I THINK your correspondent, Mr. Sheppard (see p. 155), will find his style of grid capable of considerable improvement. As I am constantly using large quantities of grids in laying out and altering gardens, &c., I have paid a good deal of attention to the subject, and find, in practice, that the plain grid recommended by Mr. Sheppard requires great nicety in fixing upon the brickwork, and is very liable to be displaced when ramming the gravel. In course of time the cesspool or eye is apt to be filled with leaves, &c., washed off the walks; then the grid, cast in one piece or rivetted together,

Scale: 2 inches to 1 foot.

must be pulled out, necessitating considerable disturbance of the gravel. To meet these objections, I have a grid cast which I now almost invariably use, and of which the accompanying is a section. The grating and box are cast separately, thus allowing the former to be lifted out at any time for the purpose of cleaning out the cesspool, &c., without disturbing the surface of the walk. The projecting flange round the bottom of the box or frame increases the bearing surface so much that any ordinary labourer can readily fix it upon the brickwork without chance of displacement. I have also discarded the old form of hollow or flat gratings, finding that a heavy shower often chokes them up with rubbish, whereas the arched form shown in the section is not liable to this defect, and is also much stronger.

J. H. CARRINGTON.

Mile End Nurseries, Stockport.

THE "SATURDAY REVIEW" ON QUEEN ANNE'S FLOWERS.

PARLIAMENT has met, Rotten Row is filling, Valentine's Day has come and gone, the birds are beginning to sing, but even "the inquiring bee" could scarcely find a flower in Hyde Park. In August, when every one is out of town, and empty chairs are all that remain to remind us of the gay toilets and crush of the season, the beds from the Marble Arch to Stanhope Gate will be in the full blaze of their gay, if not altogether harmonious, colouring. When in November people begin to return, these beds will be mounds of dark empty earth, giving passers-by a shudder as they liken them to uncared-for graves. In his delightful essay "Of Gardens," Bacon says, "I doe hold it in the Royall Ordering of Gardens, there ought

to be Gardens for all the Moneths in the Yeaere. In which, severally, Things in Beautie may then be in Season." But few modern pleasure-grounds are managed on this sound principle, although with the numberless plants and the rich variety of flowering and berried shrubs now added to our list, it ought to be much easier to arrive at the acme of good gardening than it was two hundred and fifty years ago. In those days gentlefolk were content to live all the year round in a country house. There was no social pleasure to force them to spend the sweetest months of spring and early summer in crowded streets and heated ball-rooms. A family tour on the Continent was arranged years before, and talked of years after the great event had been accomplished. The lives of those prosaic folk were still endurable to them although they had no shooting-box in the Highlands, no yacht in the Mediterranean. But now the "prince-like" gardens of which Bacon speaks, and which, he says, ought not to be less than 30 acres in extent, have to be managed on totally different principles. The great aim of an intelligent and experienced gardener in these days is to produce his best show in whatever season, be it spring or autumn, the family chance to be at home. This is by no means difficult to accomplish, although one may constantly see fine places where such an obviously necessary plan does not even seem to be attempted. It would, of course, be most unreasonable to expect the Board of Works to know at what time London is full, or during which months it is empty. For all we know to the contrary, the gardening in the parks may be for the benefit of country tourists. It would be unfair to ask men already overworked to remember that this is precisely the season of the year when a generous display of even the commonest flowers, provided they were bright in colour, would be acceptable to Her Majesty's subjects. Competitive examinations certainly do not include gardening amongst their subjects, although a useless knowledge of botanical terms is not uncommon amongst young men. But every one must have felt at some time in his life how, with the lengthening of the days, comes a desire to see things growing. It is now that we watch with impatient interest the snow transforming itself into Snowdrops, the icicles growing into catkins, the Crocuses returning with interest every ray of sunshine, though it be given grudgingly and through tearful clouds. When the east wind blows, they shelter themselves in their spiky sheaths, but are ready to open their glowing breasts at the faintest invitation from the west. It is now that we welcome the purple flush of spring on the Beeches, the wakening of the Daisies, the sprouting of the Grass, the bursting of the Lilac buds. But in the parks we must for the present be content with a few scattered Crocuses supplemented by Orange peel. We look in vain for the Hepaticas which ought to be popping their little pink or blue noses out of the ground, for the single Anemones, scarlet and purple, with which French and Italian Vineyards will shortly be carpeted, for the winter Aconite, and the hardy crimson Primroses. There are no pots of early Tulips, no patches of spring heath, no dwarf blue Scillas. We do not see any Grape Hyacinths or Dog's-tooth Violets appearing. Even if these plants had to be raised in pots it would be at no great expense or trouble. They could be easily removed when out of bloom, and replaced by other things in their season. Then, too, it would surely not be unreasonable to ask that in the borders that skirt the railings, and amongst the clumps of shrubs, there might be planted plenty of Daffodils which "come before the swallow dares," and an abundance of winter Violets, Snowdrops, and Narcissi. Unfortunately, the neglect of spring flowers of which we complain is not confined to the managers of public gardens; it exists wherever gardeners have their own way. They hate spring flowers, because they interfere with the only things gardeners think fit for a gentleman to look at—bedding-out plants. It is odd to see how these foreign plants have now almost ousted the flowers of our grandmothers' days. They appeal to the vulgar love of garish colour, they suit the taste of the people who buy tartan shawls, they are admired by those who do not think their dress perfect without the help of both a good red and a good bright yellow, and plenty of them; but, above all, they have been the fashion for the last ten or fifteen years. It is often amusing to trace a fashion as it percolates downwards. By the time it has reached the far-away sleepy country villages, something quite new and entirely opposite is really the rage amongst the upper ten thousand. Cottagers now try to fill their little plots with Geraniums and Calceolarias, which they are obliged to keep indoors at great inconvenience to themselves and loss of light to their rooms. Meantime my lady at the Court is hunting the nursery grounds for London Pride and Gentianella to make edgings in her wilderness, and for the fair tall Rockets, the Cabbage Roses, and the nodding Columbines, which her pensioners have discarded and thrown away. The disappointed gardener at the Court sees the border which he had destined for the last new and most hideous pattern of ribbon bordering turned into a lovely plantation of Lilies and Larkspur, Pentstemon and Phlox, all allowed to grow at

their own sweet will amongst hardy and sweet-scented shrubs. The beds in which he had intended to imitate as nearly as possible an oilcloth pattern are, to his horror, filled with pearl-powdered Auriculas, and Daphne Cneorum; while "Many a Rose Carnation feeds with summer spice the humming air," and blue Salvias and tree Peonies mingle with Honeysuckles and Poppies. If he has any regard for his reputation among his fellows, he will throw up his place, however much his wages may be raised to compensate his feelings for such a state of things. Thank goodness, the days of ribbon borderings and oilcloth patterns are numbered. For once, fashion has done something to encourage natural beauty and true art. We rejoice heartily, so far as the science of gardening is concerned, at the new turn of the wheel which has given us back those dear old flowers. Queen Anne has come to her own again, and the train of faithful and enthusiastic subjects with whom she has returned bring in their hands proud Turncap Lilies and stately Hollyhocks to plant against a background of moulded brick or melancholy Yew. They troop into the panelled rooms of her houses, bearing in their hands creamy white vases filled with Lavender and Lupin, which they place on emaciated tables to harmonise with the dove-coloured curtains and the straight lines of the uncomfortable sofas. They plant Passion-flowers round the porticoes and train the Musk Roses, despised but yesterday, to mingle with the ghostly Juniper, and to blush as the inhabitants look at them through the square-paned windows. We may now hope again to see lovers walking in "Alleys Spacious and Faire, hedged at both ends to keep out the wind." They will stop and look at the "Heapes," "some with Periwinkle, some with Pincks, some with Sweet William red," and they will gather "the like Low flowers, being withal Sweet and Sightly." We shall also, if Piesse and Lubin have not entirely destroyed our natural taste by their artificial productions, take care that there are aromatic herbs in our pleasure-grounds, because "the Breath of Flowers is farre Sweeter in the Aire (where it comes and goes like the Warbling of Musick) than in the hand." Bacon goes on to remind us of many a fragrant plant, and speaks of "Strawbery leaves dying which yeeld a most excellent Cordial Smell." We know of other Strawberry leaves which are also a "cordial" of the most esteemed kind in these latter days. Our grandmothers did not despise a posy of Gillyflowers and Balm of Gilead, and lovers sent each other "Rosemarie for remembrance," which was considered comforting to the brain and strengthening to the memory before Perdita put it into her garlands. The truth is, our grandmothers loved and superintended their gardens; they gave to them that air of individuality and refinement without which no drawing-room, no pleasure-ground is perfect.

Medicinal Rhubarb Grown in England.—I pointed out your remarks (p. 148) upon Turkey Rhubarb to a friend of mine, who, with myself, had always believed that *Rheum palmatum* was the source whence the drug was derived and not *Rheum officinale*. It would appear, now, that we were right; but, surely the question might easily be set at rest once and for all. It could not be a matter of much difficulty, one would think, to ascertain what plant produces so well-known a medicine as Rhubarb. My own impression is, that what is known under the name of Turkey Rhubarb is the produce of more than one species of *Rheum*; for I happen to know a person who has made a comfortable little fortune by growing the medicinal Rhubarb in England. Passing through a part of Oxfordshire last November, I saw in a district where the red soil charged with iron seemed excellent in quality, some fields in which there were strange-looking vegetable remains. These, upon closer inspection, proved to be the decayed flower-stems of Rhubarb, and, on further enquiry, I found that the fields in question were what were called celebrated Turkey Rhubarb grounds. I obtained, through the agency of a friend, some fine roots from them, and shall therefore be able to ascertain what Turkey Rhubarb grown in England really is. With the roots I also received a quantity of the prepared article—enough, in fact, to stock a small druggist's shop. Quantities of the Rhubarb from these grounds are sent to France, Belgium, and other places. I am going to have it tested and compared with what is sold as Turkey Rhubarb at a chemist's. Some of the dried pieces sent to me are 12 inches in circumference.—T. WILLIAMS.

Cement for Iron and Stone.—Glycerine and litharge stirred to a paste hardens rapidly, and makes a tolerable cement for iron upon iron, for two stone surfaces, and especially for fastening iron in stone. This cement is insoluble, and is not acted upon by strong acids. Cloth can be cemented to polished iron shafts, by first giving them a coat of best white-lead paint; this being dried hard, coat with best Russian glue dissolved in water containing a little vinegar or acetic acid.—"Iron."

TREES AND SHRUBS.

SKIMMIA JAPONICA AND FRAGRANS.

SKIMMIA JAPONICA, Thunberg tells us, was for a long time the only variety known to us. Now, however, we have at least five recognised species, viz., *S. japonica*, *oblata*, *Veitchii*, *laureola*, and *fragrans*, of the first and last of which we furnish illustrations. *S. japonica* is

Skimmia japonica.

valuable on account of its brilliant red fruit, about the size of a Pea, which, growing in profusion, remains on the bush all the year round, thus giving it a very ornamental appearance, especially in winter, and perhaps not less so in the following spring when, through this strange tenacity of adhesion, it is not unusual for the plant to

Skimmia fragrans.

be seen, as in our illustration, laden both with fruit and flowers at the same time. *Skimmia fragrans*, which bears a sweet-smelling white flower tinged with yellow, possesses this peculiarity—that though its buds appear before winter sets in, the flowers do not open till the following April. With the exception of *laureola*, which is indigenous to Nepal, all the varieties of *Skimmia* come from Japan; they are well worthy of extended cultivation, being very hardy and

adapting themselves readily, when young, to almost any soil or climate. They may be easily increased by means of cuttings struck under glass, or in some cases from seed. Siebold and Zuccarini state, says the "Revue Horticole," that the Japanese and Chinese class *S. japonica* amongst poisonous fruits.

More Great Australian Trees.—Baron Mueller, government botanist, Victoria, in his last report gives some interesting details of the results of recent explorations in the Upper Yarra, Hume River, and other districts. In the forest regions of the Upper Yarra and the southern branches of the Goulburn River, measurements were taken of some of the larger trees of *Eucalyptus amygdalina* var. *regnans*, the highest being approximately 400 feet, but it is believed that there are higher specimens, which, however, could not be measured on account of the labour of clearing away the dense jungle to get a base line. The magnificent Grass, *Festuca dives*, first discovered in West Gippsland, was found in the same districts. This Grass grows from 10 to 12 feet high, or even as to much as 17 feet in the rich soil of the Fern-tree gullies. A list of new additions to the genera of Australian plants during the year numbers fifty.

Destruction of Rome's "Garland Forest."—In Mr. Augustus J. C. Hare's book, "Walks in Rome," recently published by Dolby & Son, he alludes to the insensibility to, and want of appreciation of, landscape, sylvan, and horticultural beauty manifested by the Roman municipal authorities in carrying out recent improvements. The Villa Negroni Massimo, the most beautiful of Roman gardens, with the grandest of old Orange avenues and glorious groves of Cypresses, amid which Horace was buried; a villa whose terraces dated from the time it belonged to Mæcenæ, and which was replete with recollections of the romantic story of Vittoria Accorambuoni, of Donna Camilla Perretti, and of Alfieri, has been ruthlessly and utterly ploughed up, so that not a trace of it is left. "Even this, however," Mr. Hare goes on to say, "is as nothing, compared with the entire destruction of the beauty and charm of the grandest of the buildings which remain. The Baths of Caracalla, stripped of all their verdure and shrubs, and deprived alike of the tufted foliage amid which Shelley wrote, and the flowery carpet which so greatly enhanced their lonely solemnity, are now a series of bare, featureless walls, standing in a gravelly waste, and possess no more attraction than the ruins of a London warehouse." Then with regard to the Colosseum he writes, "The Colosseum, no longer 'a garlanded ring,' is bereaved of everything which made it so lovely and so picturesque, while botanists must for ever deplore the incomparable and strangely unique flora of the Colosseum, which Signor Rosa has caused to be carefully annihilated, even the roots of the shrubs having been extracted by the firemen, though in pulling them out more of the building has come down than five hundred years of time would have injured."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Huon Pine hardy in Wiltshire.—I find this Conifer to be quite hardy; we have a specimen of it here about 24 feet high; its habit is slender, but very graceful.—GEORGE BERRY, *Longleat, Wilts.*

Fertilising Aucubas.—The bloom buds on our male *Aucuba* are very forward and will soon open, while those on the female are still invisible. Can I do anything to check the former? It is in the open ground.—J. H. W. THOMAS, *Carlton*. [Secure the pollen when the flowers open, and keep it in lead paper until the female blooms are ready to be fertilised.]

Fine Cupressus Lawsoniana.—The finest specimen of this handsome Cypress that I have seen is in Mr. Pearson's pleasure grounds at Chilwell. It was planted a sapling in 1853, but is now 20 feet high and 30 feet in circumference close to the ground, although this width is carried up to within a foot or two of the top, its symmetry is very perfect. This particular tree appears to be more hardy than others of its kind at Chilwell. It seems, indeed, to be endowed with a Siberian constitution.—J. MUIR.

The Mammoth Tree in the Atlantic States.—Mr. Meehan says, in his "Gardener's Monthly," that the Mammoth tree has not proved a success in the Atlantic States. It gets diseased in summer, and after a few years dies away. Of hundreds set out around Philadelphia, he only knows of one living now, and this is sheltered from the summer sun by tall white Pines. No winds or frosts have hurt it. The cool shade, however, keeps the summer complaint from being rapid enough to destroy it. Three-fourths of the lower branches are killed; but it seems to keep a little ahead of death.

When Should Hollies be Pruned?—What is the best time to prune and cut into shape a large Silver Queen Holly that has been neglected for three or four years, and sadly wants bringing back to its lost pyramidal shape. My own opinion is that it should be done in March, but I fear committing a blunder that may be disastrous to a splendid tree 25 feet in height.—HIN, *Bromsgrove*. [I have no hesitation in recommending your correspondent to cut in his Silver Queen Holly at this season. I have pruned Hollies both in spring and autumn, and never found any bad effects to be the result. After the operation, darken the cut extremities of the branches, stir up the surface of the ground with a fork, and place some good rich soil over the roots. The cutting in of many of the Hollies in this garden (to make them assume a pyramidal shape) was done about a fortnight ago.—JAMES McNAB, *Royal Botanic Garden, Edinburgh.*]

PROF. NEWMAN ON FRUITS AND VEGETABLES AS FOOD.*

At the editor's request, I begin this article with a few words on my personal experience of vegetarianism. I was led to study the question during the first cattle murrain, and approached it on the side of political economy and for avoidance of disease among the poor. I did not at all believe it could suit me personally, yet was ashamed to talk or write in favour of it without at least trying it. Upon trial I soon found my digestion to improve—carefully rejecting white bread, and getting the brownest which was to be had. I had previously, by medical order, eaten flesh meat regularly twice a day, and rather largely. Dinner pills were ordered me to assist digestion of so much meat. These I abandoned with flesh food, and have never resumed them. My general health is better than I can remember it, nor has my enjoyment of food at all lessened. In my seventieth year I need neither doctors nor medicine. By general testimony the colour of my skin and fulness of my cheeks have much improved under this diet, which I would now on no account give up, though I adopted it with much more of fear than of hope. The increased price of flesh meat has become an untractable fact, distressing to the gentry who cannot increase their income, and to thousands of small households in our vast trading community. To the artisans who have acquired habits of flesh-eating in the last twenty-five years, it neutralises the advantage of their higher wages, even when they are abstinent or very moderate as to intoxicating drinks. Necessarily then, the whole question of this diet is coming forward into fuller discussion, and interests thousands who a few years ago never gave continuous or attentive thought to it. There are three main topics, on one or all of which those who assume the name Vegetarians base their abstinence from the flesh of animals:—The argument of economy (private or national); the argument of physiology—which bears on health, longevity, and even moral temperament; thirdly, the argument from the rights of animals. To different minds these arguments bear a different scale of importance. Naturally, to statesmen the argument of national economy, determining the population which a given area of soil can feed, will seem primary in this question; but to those who, not through poverty, abstain from flesh food, the other arguments will generally take the lead. The author of the classical work on "Fruits and Farinacea" was brought to renounce flesh meat from being led to study the basis of our rights over the lives of animals. He came to the conclusion that without decisive and urgent necessity we have no right to deprive harmless animals of life; and on pursuing his enquiry further, he convinced himself that to feed on their flesh does not conduce to superior health, strength, or longevity, but contrariwise. Beginning from this side of the subject, he worked out the whole of it, so that it is hard to say which of the three topics he regarded as the principal one. The late Mr. Brotherton, long distinguished in Parliament as the Vegetarian member, and signalised for vigour in advancing years, certainly gave no practical prominence to the economy of vegetarianism; and probably, like Mr. John Smith, was allured to it on what may be called the Brahminical side, by the tenderness of his nature and his strong sense of universal justice. One might gather from the comments of the public prints on the vegetarian festivals of those days, that the leading vegetarians some twenty years ago were more anxious to convince rich men what luxurious repasts they could give, without flesh food, by elaborate cookery, than to show to poor men—and to all who desired to spend as little as might be on lower appetite—how simple and cheap is a satisfying vegetarian fare. Of course, it is possible to be as extravagant on one form of cookery as on another. There is no upper limit. It is only concerning the lower limit that there can be any available discussion.

The topic of health and longevity is naturally prominent with all vegetarian physicians. Dr. Lambe, in the past generation, gave a life-long adhesion to this practice, and an enthusiastic advocacy of its excellence. Before him Dr. Cheyne, of Bath, though less consistent and thorough-going, gave very remarkable testimonies, especially to the efficacy of vegetarian diet in chronic diseases. It must at once appear how many important enquiries crowd in, as soon as the relation of diet to the health of invalids is touched. While men and women are in rude health, and live simply, without excess, the stomach digests with seeming indifference a vast variety of food. Whatever can nourish appears to be healthful, and all scruple about the kind of food sounds like pedantry or superfluous care. Not so with invalids. Not so with those who live a sedentary life—those who disproportionately use the brain—those whose nervous system is overstimulated—those who have no full and regular muscular action. In these health cannot be robust and rude; and if food less natural to man—that is, less completely suited to his organisation, be used, one may reasonably expect frequent damage to health and some shortening of life unawares. When it is manifest how large a frac-

tion of English diseases among our middle and upper classes arise from the stomach, diet must assume a first-rate importance with physicians; though it is said (probably with truth) that our townsmen and our upper classes, and the servants of the rich, suffer far more from excess in quantity than from any error in quality. With such complexity in the questions concerned, there is evidently room for great variety in the details of vegetarian practice. We might expect, what indeed we find, a few vegetarians rigid in the extreme. The late Mr. George Dornbusch, of Threadneedle Street, went even beyond vegetarianism. He not only abstained from all the received animal foods—from everything that had had animal life, and from eggs, milk and its products, but from every form of vegetable grease or oil, from the chief vegetable spices, such as pepper and ginger, and emphatically from salt. The present writer, in a long conversation with him, entirely failed in discovering, beyond the argument that salt is a mineral, any other ground for these abstinences than that they agreed best with him. He took only two meals in the day, and could boast of unbroken health in very continuous business. On one remarkable occasion he was assailed in the street by an escaped lunatic, who stabbed him in twenty-three places. He went into the first chemist's shop, and got his wounds bound up. Loss of blood caused him much weakness, forcing him to be absent from business for a fortnight; but he wanted no medical advice, nor any drugs: every wound healed easily, and he was soon perfectly recovered. Finally, through too much trust in the strength of his constitution, he exposed himself unwisely to cold when already suffering from bronchitis, and the hot bath did not save him from being carried off in the midst of vigorous life. Another gentleman informed me, that without knowing that there was a Vegetarian Society in England, or being acquainted with anyone who followed their tenet, he once lived for three years on fruits only, and is convinced that at no time in his life was he so strong; but he gave it up from the inconveniences of the practice. A few vegetarians (only a small fraction of those known) abstain from milk and eggs as severely as from beast, bird, and fish; some, from the desire to carry a principle through so completely as to avoid all cavil; others, from the consideration that so long as there is a demand for milk male calves and oxen will be killed for the table, and probably the cows also before they pass middle age.

Another possible form of abstinence is regarded by the Vegetarian Society as far too imperfect to be recognised at all or to deserve a name; yet there is no compromise so likely to be widely adopted by our nation as that alluded to, viz.: to abstain from quadruped and fowl, but accept fish and marine animals. Inasmuch as no pure vegetarians can reasonably hope that a nation long accustomed to flesh-meat will collectively change its habit, except in the course of several generations, this imperfect form of abstinence might seem to deserve their warm encouragement. Fish do not occupy arable land. Fish have no family life or family affection. To take one life does not torture another. They are, themselves, nearly all fish-eaters. Our capture of them generally is, and ought always to be, painless. If it be admitted to a severe vegetarian (what is hard to prove) that to eat a fish-dinner once a week somewhat shortens life, yet perhaps no vegetarian will assert that the use of marine sauces, or of caviar, or of isinglass, has any such tendency. Hence a diet, such as poorer men would naturally take, resorting to marine products rather as an aid to cookery than for the substance of food, appears to reduce the objections of vegetarians to a minimum. I may be permitted to dwell a little on this topic. While on the whole, to any family of the gentry or of thriving shopmen, a vegetarian diet which admits milk and eggs sparingly may be far cheaper than one into which butchers' meat, pork, fowl, and fish freely enter, those who are a little poorer find gravy and fats hard to dispense with, because of the high price to which good butter is run up. Suet, indeed, itself is dear, good oil is dearer; mustard oil might, perhaps, be very cheap, and is largely used by the poor in India; but at present bacon-fat, lard, and dripping have strong hold of the common imagination; moreover, such articles as sprats, bloaters, herrings, and sauces made of marine animals, give either strong taste or oiliness to many forms of food which, unless skilfully cooked and seasoned, are judged mawkish. Instinct is quite right in demanding flavour, and a fair supply of oleaginous material. The poor, nay, the whole nation, has yet to learn how to cook well and with least trouble. It is new to the present generation of English workmen to have butchers' meat even once a day; a little wise persuasion may induce many to abstain from it on principle, as their fathers did from necessity; but to refuse not bacon-fat only, but also red herrings, bloaters, and sprats, is a still harder thing for those who cannot afford butter—who have no supply of savoury herbs, and no experience in cooking. If any mass of our workmen could be induced to adopt the more moderate abstinence of accepting the animal produce of the seas, but refusing that of the land, many of the most valuable results claimed by

* From "Fraser's Magazine" for February.

vegetarians would be obtained. Besides, if the principle of studying what is the best food once gains ascendancy, the more severe rule surely wins on the laxer. But even by the laxer rule we should reverse the error made from 1847 onward. In 1845 and 1846, before the actual repeal of the Corn Laws, it was predicted by Colonel (General) Perronet Thompson and Colonel Torrens, advocates of the repeal, that one result would be a great increase of demand for butchers' meat, dairy produce, and garden vegetables, by which the farmers would grow rich. So it shortly proved. As fast as wages rose in the towns through increased commercial prosperity, the artisan population consumed more and more of flesh meat. By a coincidence no doubt accidental, in 1847 the Vegetarian Society was formed, and year by year proclaimed to the multitude the wisdom of saving their money by a more economic diet, which was on several other grounds far better. But the newspapers treated them with ridicule; the medical practitioners and the employers of navvies zealously preached up butcher's meat; the mass of the nation never had the arguments brought before them; the rush after flesh-meat continued, until murrain after murrain resulted among the cattle; panic followed; public slaughtering was commanded, in order to "stamp out" the disease; prices already high, were hoisted higher and higher, until many began to ask whence this had arisen, and in what it would end?

No effort is here made to exhibit the immense mass of broad facts, based on the state of whole nations, which proved decisively that vegetarian diet is able to produce the maximum of human strength. As usual, men pretending to science quote cases of navvies who worked better on rumpsteaks and such-like narrow experiences, which always admit a simple solution:—"Pay men better, and they work with a hearty will: pay them better, and they also rush into sensual indulgence." But these overfed navvies are not healthy. The tale of them is that of athletes according to Aristotle, who were wholly unsound, because they "over-ate and over-worked." The reader must be referred to the pages of Mr. John Smith, of Malton, or rather to its abridgment by the Vegetarian Society, for the abundant evidence of the remarkable strength of nations who feed on grain and other fruits of the earth. Hitherto, as has often perhaps been remarked, the rich eat whatever they like, and the poor whatever they can get; few, indeed, appear to have made the enquiry, either morally or physiologically, what is best for a nation to eat? On the other side of the Atlantic we have a warning to what our national habits tend. In the American Union physical abundance has long reached the lowest class; butchers' meat is eaten as often as they please by the population in town and country; and no part of the English race is so unhealthy as they. Stomach-ailments, and nostrums to relieve them, abound there as nowhere else; a prevalent haggard aspect seems to tell of unsound nourishment; but, possibly, over-work of brain may in many cases conspire to the result. In Australia, some allege, the Yankee type of countenance already appears: but all is too new there to rest an argument on. In New York and the neighbourhood, in order to get a sufficient supply of milk, the cows are fed on the refuse of distilleries, by which the quantity of the milk is increased, and the quality deteriorated. Moreover the cows, confined in cellars, become emaciated and diseased. Such are the mischiefs which our artificial modern contrivances entail.

A second evil of the great demand for butchers' meat and dairy produce is, that the high price makes it worth while to restore cultivated land to Grass. The farmer saves the wages of tillage, of weeding, and of gathering crops; yet one cannot tell, *a priori*, whether he would prefer to devote the fields to crops for the consumption of cattle, and (perhaps) keep the animals in stables. But it is sufficiently testified in the Government Blue Book that in Ireland land is now given back to Grass, in order to rear more cattle and sheep. Hereby the soil is rendered immensely less productive of human food. The rustic population are less needed, and must be driven into towns to compete for work, or swell the ranks of paupers or emigrate to enrich other soils; while our towns become more and more dependent on the foreigner for food. This stage of national existence, denoted by overgrown towns, and rural places occupied by many cattle and few men, strongly marks the period of decay, and cannot too soon alarm us. But it will be observed, that whether a population eats or does not eat fish, neither usage promotes any of the evils which (in our present national stage) attach to a general coveting of butchers' meat. The supply of fish is just so much added to the national food, without using up an acre of cultivable land. It cannot cause displacement of rustic labour. Dead fish may, no doubt, be sold when unwholesome; so may vegetables; but to beware of each evil is comparatively easy. The fish is ordinarily brought to shore alive, in a perfectly natural state, in its own element. Hitherto, however, most fish is far too dear for the consumption of the millions. The argument here pressed is simply that, from the vegetarian point of view it is of comparatively slight importance at the

present crisis to induce the mass of the people to forswear fish as such. Few of them will get any other fish than sprats, skates, and, at certain times, mackerel and herrings; indeed, except near seaports, the supply will be generally confined to salted articles. If a pledge conduce to steadiness of conduct (as many find it does) it would seem expedient to have a series of pledges varying in stringency, so that each may select that which his circumstances allow him to carry out. But we turn now to a side of the subject which must grow in importance—the supply of milk. It was mentioned that the Vegetarian Society, while condemning suet and gravy, distinctly permits the use of milk, butter, and cheese. But milk and butter, alas! are now most difficult for our rustics to obtain. The railroads give facilities of transport, and the towns buy up the dairy produce wholesale. In many places it is a certain fact that farmers contract to supply so much that they have little or nothing left to sell to their own neighbours. If to Potatoes buttermilk can be added, an Irishman gets all that Nature needs; but if not even buttermilk can be got, Potatoes are not a sufficient food, nor is brown wheaten bread by itself palatable, unless it be in its prime of excellence. Charitable persons have been known to purchase preserved Swiss milk, dilute it with the due proportion of hot water, and sell it, as a charity, to our peasants, who otherwise had no chance of purchasing milk at all. When such facts raised the enquiry, "Could not our rustics have cows of their own, if a run for them were allowed?" the thought moved a nobleman, whose philanthropy we do not call in question, to abrupt laughter, so absurdly impossible did he regard it. Yet in other countries it is not impossible; and even in Scotland some large farmers deem it for their interest to allow cow-pasture to their labourers. Over the peasant's inability to get meat-fibre as food, it is not necessary to mourn; but the deprivation of even skim-milk and buttermilk is a very serious fact which urgently calls for remedy. Even wandering Arabs and Turcomans, who rarely taste flesh, account milk and its products a very important part of food. That our greedy towns should be able to buy all up, and leave the peasants empty, is a national scandal. Evidently the milk ought in some sense to be in the peasant's own hands, so that he may have the option of detaining it for the use of his family.

It is generally imagined that in vegetarian cookery great quantities of milk and eggs are necessarily used. This is a gross mistake; and some vegetarians do not use these articles at all. Still, it is unfortunate that, when they are not entirely renounced, it is always open to opponents to assert that they are inordinately used; and this often is asserted very broadly, though without any attempt at proof, proof and disproof being alike difficult. The assertion springs out of two erroneous assumptions—(1) that there is in every vegetarian a craving after the nitrogenous element supplied by the lean of meat, by milk, and by eggs; (2) that the supply cannot be obtained from purely vegetarian food. The second error ought not to be made in the present state of science. For more than twenty years it has been notorious, and conceded beyond controversy, that the gluten of wheaten brown bread and of barley is chemically identical with albumen; that is to say, with the substance of flesh meat; also that Beans, Peas, and Lentils are richer in nitrogen than is lean beef itself. The purest vegetarian does not need to suffer from any deficiency of nitrogenous food, and vegetarians in general steadily deny that they have any craving for such food. Indeed, it has been in more recent years ascertained that the nitrogenous or flesh-forming element is of immensely less importance than the heat-giving element, for the latter is that which gives vital force. If a man works very hard, he somewhat wears away the muscular tissues, on which account he needs a little more of albumen; but the exhaustion of vital force is by far the graver drain upon him, and, even when we work least, there must be large expenditure of the latter kind. Starchy and oily substances supply heat and force; and these substances abound in the vegetable world. If any vegetarians are extravagant in milk and eggs, it is not from any craving of their stomachs, but from excess of zeal or ignorance in their cooks. In every house of moderate wealth, the cook likes to make her dishes highly palatable, and will probably be lavish in the use of these popular delicacies, unless steadily checked by the mistress. To the present writer, ever since he has adopted vegetarian practice, it has been matter of conscience not to increase his use of eggs and milk—of milk especially; because, to make a run on it, involves all the same evils as to make a run on butchers' meat. In fact, if anyone can reconcile himself to the use of oil in cookery, there is no difficulty whatever; otherwise, there is probably a necessary increase in the use of butter in preparing vegetables when other animal fats are refused. Different vegetable oils have, no doubt, different flavours; and a little more experience will teach us how, by a slight addition of vegetable acid or of some savoury herb, any taste of an oil offensive to an individual may be corrected. Skim-milk, buttermilk, and cheese retain the nitrogenous element; hence, added to Potatoes or

bread, they make very complete human food. In buying up the country butter, the towns do not rob the rustics quite so cruelly as when they take the milk itself; still, it is very inexpedient and essentially unfair. If vegetarians are to hold up a noble and profitable example to others, they must not only jealously restrict their own consumption of milk and its products, but ever be aiming to lessen it. The argument on this side would become prudential and personal, if we could believe that the statements about pestilential milk which have had currency in our newspapers point at any general facts and soundly expound principles. Cows, it is said, were fed on unwholesome Grass (and were not visibly and at once made ill); but their milk instantly became pestilential, and whole families suffered mysterious disease from it. There has been plenty of unwholesome water and herbage too, in all past ages, to do cows harm, if their instinct did not avoid it. Have our cows suddenly lost skill in the choice of food? When, by an excessive use of liquid manure, the Grass of a meadow has been made pestilential, if cows, through hunger, eat it, and it be poisonous to their milk, must it not first be poisonous to their blood and quickly alarm the cowkeeper? Do men wish to poison their own cows? or, can they do so, and be blind to the fact? One may be pardoned some incredulity, however respectable the medical authority which is said to have traced the evil home to its source.

To return to the question of national consumption, it is beyond dispute that, by an injudicious choice of food, a nation may starve upon a soil which is amply sufficient for it. Horses we keep, not to feed on, but for service. But oxen are no longer used for the plough or the cart, or very rarely—they are raised for food; and to get the same amount of human food through them needs three or four times as much land as would be required if we fed directly on crops of grain, pulse, Potatoes, or fruit suitable to our climate. So little are the minds of even educated people exercised on these topics, that ridiculous objections are constantly made by them. "How can you get nitrogenous food to make you muscular, if you do not eat beef and mutton?" asks one gentleman who has a smattering of chemistry. But how do the bull and the horse get their muscle without eating flesh? Evidently they get it, not only out of grain, but even out of Grass, to which our organs are not equal; but the element must be in the Grass, unless you admit they get nitrogen from the air by breathing; and if they can, so can we quite as well. "What will you do for manure?" says another, "if you do not keep cattle?" But if you return to the soil all refuse of plants, and, in short, whatever you take out of it, no exhaustion can follow. Exhaustion is caused if you send the whole crop clear away, as, not least, when you annually export herds of cattle. "The oxen would eat us up if we did not eat them," is also a common remark. But why, then, do not the horses, whom we do not eat, eat us up? Our graziers do their utmost to multiply the oxen, yet the objector is not aware that their number is now artificially great. In fact, the oxen may be justly said now to eat us up, for they lessen largely the number of men who can live from our soil. Our whole treatment of these cattle is quite against Nature. Fifty and a hundred years ago the employment of oxen for the plough was in many counties still kept up, and there is no adequate reason why, in the nineteenth century, and with an improved breed, all the heaviest work on a farm should not be done by the bulls, as it was in Virgil's day. High-bred bulls walk faster than heavy cart-horses, and might advantageously supersede them. If fondled from early days, they are quite gentle; and, what is more, they are stronger for draught than horses. The very form of the horse marks him as designed for swiftness, that of the bull for weight and strength. Give back to the bull his functions in agriculture, and you will not need to ask, "What can we do with him if we will not eat him?" any more than concerning the horse. While it is in many ways evident that for national economy—for a wise application of national resources—we ought to feed on the direct produce of the soil, the arguments of private economy come home more quickly to each man if only he have that confidence in general reasoning which some study of numbers and mathematics ought to give to all of us. For we have the positive testimony of the first chemists as to the vast superiority of grain and pulse, and dried Cabbage, or dried Cauliflower, and Nuts, and dried Apples, and Potatoes, to equal weights of dried meat; so that it is very easy to convince oneself that a flesh diet is the more expensive; indeed, when largely indulged in, it is a scandalous extravagance. But inasmuch as we are guided to food—not indeed by pure instinct, but by a habit which takes the place of instinct—and our taste generally demands what is habitual; most persons are incredulous as to unusual dishes, and insist that *soupe maigre* must always be a "meagre" thing, and that without, at least, meat gravies we could not have palatable dinners. Only the few have strength of mind to resist the tyranny of customary tastes. Yet it is certain that the zest of food mainly depends on a healthy stomach and a keen appetite; and that the vegetable world has

countless delicious flavours, far outnumbering those of the few animals whose flesh we eat. There is no basis for the prejudice which here is often so obstinate. To begin with broth: the broth from Peas, Beans, or Lentils, is far superior to that from mutton. The flavour given by Celery, with Onions or Leeks, to vegetable soup competes with anything that flesh can give. Mushrooms of several kinds surpass in delicacy and flavour the best of chops and steaks, which, indeed, often owe much to Mushroom ketchup or Horseradish sauce, or Tomatoes or Capers, not to mention pepper and salt, curry and spices. The very cheap savoury herbs, which the poorest person can command, are numerous—as Mint, Thyme, Lemon Thyme, Sage, Fennel, Balm, Sweet Marjoram, Horseradish; from which, with ketchup or Celery, compounds may be made, giving flavour to every combination of leaves or roots, or to grain and pulse, without thinking of milk or eggs, or even cheese. It is only prejudice and ignorance of cookery that keeps people incredulous. But for this very reason it is a matter of first-rate importance to have in every great town at least one vegetarian restaurant set up, with substantial and pleasant dinners, at a price not to exceed sixpence. This can easily be done, and would be done in a month's time, only that the Vegetarian Society is very poor, and cannot run risks with its narrow funds. In New York a philanthropic gentleman started such a shop, which is said to be a success; and there is every reason why it should be so, if a right selection be made of its conductor. He (or she) must be a thorough vegetarian at heart, zealous for the cause, as well as clever in business, and up to the mark in cookery. Such an establishment would have an immense advantage over an ordinary eating house, in the fact that grain, Potatoes, and pulse, which are the staple in vegetarianism, all keep a long time quite unharmed, while flesh is spoiled in a week. This is one of the causes which has made "licensed victuallers" degenerate into mere drink sellers. Beer and gin keep well, and meat does not. Of course, nothing but trial will convince the public how advantageous and satisfactory are vegetarian dinners, and there must be a risk, probably a loss, before an attempt succeeds, because, at first, things cannot go on by routine and order; judgment is constantly needed, when to make large purchases, how to select, for what to prepare; nor can it at first be certain what class of dishes and what form of food will be most popular. Philanthropy and wealth are often found closely combined in London and in our manufacturing towns. If a few rich men, anxious for the public welfare, would take this task in hand, consulting with the Vegetarian Society, they might soon have very gratifying success. It may be well here to name, that anyone without any pledge as to his diet, may become an Associate of the Vegetarian Society by a simple declaration that he desires to promote the diffusion of their literature, and by subscribing (as a minimum sum) 2s. 6d. annually to their funds; which will entitle him to receive the "Dietetic Reformer," their monthly organ. The patron of a vegetarian eating-house, by becoming an Associate of the Society would obtain their zealous co-operation; but, of course, would remain uncontrolled on his own ground.

In the course of last year a challenge was made and accepted in Birmingham, which bears directly on the subject now treated. A vegetarian, twitted by an opponent with the expensiveness of his cookery, declared that he could give a dinner to twelve persons for five shillings. The opponent nailed him to his word, and defied him to make it good. It had been uttered rashly, yet he proceeded to justify himself. The conditions were written down. The dinner was to be (1) satisfying to the appetite; (2) grateful to the taste; (3) not displeasing to the eye; the price of the articles was not to exceed five shillings, but the price of coals and cookery was not to be included. In the result, not twelve persons only, but sixteen, joined in the dinner. It consisted of soup, Potatoes, Vegetable Marrows, stuffed with Sage and Onions, and baked; Plum pudding, Apple pie, Damson pie, and small Damson tart. The company was abundantly satisfied, and the gentleman who had challenged was foremost in confessing that the three conditions had been honourably fulfilled. The bill was then produced, by which it appeared that the cost had been one halfpenny less than the stipulated five shillings. It stands thus:—15 lbs. Potatoes, 9d.; 2½ lbs. flour, 6½d.; ½ lb. butter, 7d.; Vegetable Marrows, 9d.; Sage and Onions, 2d.; Split Peas, 2d. Celery and Carrots, 1½d.; Apples and Damsons, 10½d.; Raisins and Currants, 6d.; Sugar, 3d.; Milk, 2d.; Candied peel, 1d.—Total, 4s. 11½d.

On reading the names of the dishes, it might seem that the sweet predominated over the savoury; but the expense shows nearly 3s. to the savoury and 2s. to the sweets. It will be remarked that the small sum of 2d. gave milk for sixteen persons, while butter claimed the larger sum of 7d. Together, this is only 9d. out of 5s. Of course this dinner is only one out of a hundred that might be given; indeed, it is not everyone who likes Vegetable Marrow, nor is it easy to believe it substantial. One may believe that the Potatoes and the

Peas, giving starch and nitrogen, bore the brunt of the battle on this occasion; but the fruit also (costing 19½d. with the sugar) gave no despicable aid. Apples are often as cheap as Potatoes, and it is said they might be much cheaper. Of all food, in most climates, fruit produces the maximum yield for a given area. In Ceylon it may be in Cocoa-nuts, in the plains of India from some other Palm, or from Bananas; in France, Chestnuts are the most productive crop; in England it may be Cobnuts, or it may be Apples; and the union of the two is as admirable in food as bread and cheese, or as Figs and Walnuts. Fruit, which our richer classes treat as a toy and eat for amusement, ought to be a main part of our national food; and the cheapness of sugar gives us a wonderful facility in turning to service whatever our often harsh climate does but imperfectly ripen. Wheat is often called the staff of life, yet it is astonishing how slow we are to learn its dietetic value. Indeed, because it is too nourishing, and quickly dulls the appetite, all its most nutritive part is carefully extracted by our clever confectioners, until it is made as light as possible, in the form, perhaps, of a French roll or a Sally Lunn. Our ancestors boiled it and ate it as "firmity" (frumenty). Now-a-days, this is turned into a sweet dish, which is eaten as a curiosity at certain times of the year. The confectioners boil the grains whole, which makes the husks disagreeable in the mouth. The Syrians managed this dish far better. It is the standard daily food with the mass of the people, and is called by the unmelodious name *berghal*. The Wheat is cracked, not ground, and then boiled—half an hour seems fully to suffice. They eat it with curds of milk, the oxygala of the modern Greeks; and no more tire of it, all the year through, than we tire of bread and butter at breakfast. This is one mark that some simple combination of food thoroughly satisfies Nature—that we do not hanker after a change. In this sense, one of the refutations of flesh food is, that we ill endure the same dinner every day. Wheat, treated as by the Syrians, is called by the American vegetarians Wheat mush, and it is best to adhere to this name. I find that after it is boiled, a little Onion, sliced fine and fried, then mixed in with butter or oil, and a pinch of savoury herbs, makes the mush highly palatable. Some persons indeed have mistaken it for minced mutton, when so dressed. There always remains something to bite, as the Wheat is not ground, but only cracked. Lentils are another very delicate and very nutritious article, which the English public scarcely uses. Peas and Beans are almost identical with it, only coarser. Barley, by the richness of its gluten, is far superior to Rice, and either dressed as a pudding with raisins, or as a soup, gives a very substantial meal. In short, no one can look into the subject and make a few trials without seeing the enormous resources at our side, which are now wasted through an exclusive zeal for butchers' meat—the food of comparative barbarism. We have but to hope that men will arise able and willing to advance and risk or contribute funds, in order that Vegetarian eating-houses may have a fair trial. The superior cheapness and fully equal niceness of their food, it may be reasonably hoped, would call back our artisans from the vain chase of flesh meat. Probably it would be found desirable to begin by the system called by us ordinaries; in France *table d'hôte*. Guests would not at first know how to order a dinner, and it is even better that they should not. To be able to produce at once whatever is required, is only the result of long experience, and by an incipient system could not be undertaken with more than a very few staple dishes; indeed, a higher charge ought to be made for every thing demanded at irregular hours or out of the routine. In a populous town, large numbers of clerks and artisans would be satisfied by the system of ordinaries, if the food itself satisfied them. Trial would soon ascertain whether breakfast would need any change. For those who like some warm cheap food at breakfast, and do not take kindly to oatmeal porridge (which ought to be always coarsely ground, little more than cracked, and never swallowed without biting), nothing is easier to prepare and more palatable than yesterday's Potatoes fried up with a little sliced Onion. The nitrogen in the Onion will in the long run please most persons, and to a really healthy stomach it brings no after-taste. So far the argument has proceeded, first on that side of the question to which a statesman will chiefly look; and we may complete it by observing that, however some economists may talk about our being over-peopled, it is certain that every English ministry in the future will be constantly exercised by the problem—how to keep our people at home and secure an increase of their numbers. More than ever is it manifest that in the long run the power of every European nation will rise or sink with the numbers of its population. Spain is on this ground left behind in the race. German statesmen are already alarmed at the drain from emigration. Russia increases her numbers steadily, and loses none to the New World. Russia and North America already alarm all Europe by the colossal magnitude which they are certain to attain. To equal them is impossible; but it appertains much to English security and dignity that these three

kingdoms should have a population of sixty millions rather than of thirty; and it is certain that under wiser diet and improved land tenure, we could as easily feed sixty millions from the soil itself, as we now feed thirty with the help of enormous importation. Secondly, and more concisely, we may turn to the physiological question—the healthfulness of a vegetarian diet. A popular topic here at once applies. Physicians agree that, except our poorest, the nation habitually eats too much, and that this is a very prevalent source of disease. The very common phenomenon of a heaviness which before the age of fifty, damages Englishmen's activity, seems to point at over-feeding. Now a flesh diet, by its smallness in bulk, directly tends to this evil. It does not fill the stomach, yet the stomach does not act well unless distended. For this reason innutritious food, whether hay, straw, chaff, shavings, even sawdust, is needed by cattle who are fed on grain; and all condensed food is unwholesome, even dangerous. By reason of the condensed nature of flesh meat, everyone who depends on it is tempted to take in more than his stomach can deal with; hence the doctor orders dinner pills to fortify us for a larger dose of flesh food. If they succeed, the patient retains health, but wastes on his vegetative functions the strength which otherwise would have been at his voluntary disposal. But if his system is not equal to the effort, the superfluous food loads him with unwholesome fat, clogs his vital organs, and wearies his muscles with his own weight. But beyond this the subject admits, and has received, a purely scientific treatment. Only the outlines can be here sketched. First, what are the diseases by which our richer classes are chiefly attacked? Those which stand in close relation to gout. Dr. Prout recounts them as "strumous, lithic-acid, and gouty diseases," and attributes them to an imperfect assimilation of the albuminous principles of food; that is to say, to an excess in flesh diet. Next, what classes of men recover best from wounds and severe accidents? Much important testimony affirms it is those who eat least of flesh meat. Eminent surgeons testify that in this respect the Indians and the Chinese far surpass the English soldiers, and attribute it to "their vegetable regimen." As gout is not heard of among Irish peasants, so too, it is alleged, their blood is less inflammable than that of well-fed Englishmen, and they recover better from severe hurts. Thirdly, it is claimed that vegetarians have more exemptions from the attacks of epidemic disease than flesh eaters; in particular it is denied that any case of cholera has been found among them. Fourthly, it is admitted by physiologists in general that the cases of extreme longevity are almost solely found among vegetarians. Of course many things must conspire that an individual may attain the greatest age possible to man. He must have had no hereditary weakness, no violent shock from accident or acute disease, no permanent excess of toil or distressing care, no long exposure to bad atmosphere in cities; and if vegetarian food is of critical importance, he must have been a vegetarian from childhood: then possibly he will live to the age of a hundred. It is ridiculous to expect that by adopting this practice late in life an individual can become signal in longevity; yet it is maintained he may somewhat lengthen his years, especially because the diet itself suffices to cure many maladies, probably by the greater purity which it gives to the blood. The case of Professor Adam Ferguson is signal and notorious. When past fifty he was seized with very alarming paralysis. His friend, Dr. Black, the celebrated discoverer of latent heat, who was no vegetarian, was called in to treat him, and prescribed a strict vegetarian and milk diet. Under this he entirely recovered; ate no meat and drank only water or weak tea for the rest of his life; had no second attack, and after the age of seventy was remarkably hearty, continuing in much vigour until almost ninety. He lived to ninety-three. The effect of a mere vegetarian diet to renew shattered life appears here undeniable. Fifthly, fruit, which is presumed to have been the food of original man—of man who is born "a tropical product," with hairless body—fruit is to him peculiarly medicine as well as food. The Germans have their "Grape cure," and among fruits let Grapes by all means have a most honourable mention; yet happily they do not stand alone. When a child was covered with ulcers from head to foot, and blinded by them—when physicians despaired and confessed drugs to be useless—Mr. S. Rowbotham, a surgeon of Stockport, guiltless of vegetarian theory, cured the patient perfectly in a few months by a diet of stewed English fruit and honey. Sixthly, to pass from these details of experience to the higher region of comparative anatomy and physiology, it is contended that the interior organs and teeth of man show him to have been made for a frugivorous animal. To this day even surgeons and physicians of eminence may be heard to say (what betrays an ignorance in them disgraceful), that our canine teeth show us to be made for tearing flesh. That this is a gross error is no new discovery. Linnæus, Gassendi, Ray, Cuvier, Thomas Bell, Lawrence, equally with Professor Richard Owen, avow our teeth not to be canine, but to be nearest to apes' teeth. Their

fangs are indeed larger than ours, and well adapted to crack strong nut-shells; but none of them in a state of Nature eat flesh. Indeed, anyone who examines a dog's teeth sees at once the entire contrast; yet our scientific men (so called) allow the epithet canine to run away with them! A close comparison of the digestive organs in man with those of the domestic animals on the one side, and of the carnivora on the other, shows distinctly that his organs are intermediate, as are those of the apes. The entire argument is very extensive. Mr. John Smith develops it in his "Fruits and Farnacea"; here it can only be pointed at. He admits that art and the use of fire make flesh tolerable to us as food, but denies that that which art enables us to do can ever thereby become normally necessary, or tend to so great robustness as the use of that food to which our physiology and anatomy direct us. The mediate place between herbivorous and carnivorous animals is denoted by the epithet frugivorous. This is the place of man; also of the apes and monkeys; apparently too of the bear and the pig. The horse also has some approximation to the human organs, perhaps because grain is a food so well suited to him. Seventhly, in detail certain peculiarities are alleged, to which a reader (if he concedes the facts to be all correct) will give what weight he thinks they deserve. It is said that no carnivorous animals sweat; and since man sweats this allies him more closely to the herbivora. It is further said, that in the carnivora the salivary glands are comparatively small, in the herbivora very large; and the reason too is plain: the herbivora masticate their food with their broad grinders, and need saliva for the operation; but the carnivora never grind food, they have no grinders, and they cannot masticate. Now, in all these points, man resembles the herbivora. The present writer, however, must confess that he is here at a loss concerning the facts. A subtle question often arises, What is natural to man? Is not art natural? Fire removes evil juices from Potatoes. Vegetarians will not renounce this use of fire. They steep Beans and Barley, they grind or crack grain, they boil, stew, and bake at pleasure. Mills and stewpots were not born with the first human pair: they are after-inventions of human art. So is the roasting of flesh. Why, then, may we not call this natural, just as baking bread is natural, because each is naturally developed during the growth of the human intellect? Of cookery, in the abstract, we must admit this. Cookery is requisite to make the greater portion of a flesh diet endurable to us; and without this a large part of the world could hardly have afforded food for man in his barbarism. In this intermediate state we may agree to call Homer's cookery of a bull "natural" to man. But, if we claim to appeal to evolution in defining what is man's nature—if we contend that that is our truest nature to which we tend in our nobler and advancing condition (a very just and wise view)—then we are carried to the conclusion that vegetarian food, being the inevitable future of every thickly peopled nation, is the practice that must be avowed as alone suited to our highest and noblest development. Man in tropical regions began from it. Driven into ruder climes, and unable to live on crops fresh sown, or on fruits not yet ripe, he was forced by harsh circumstances to feed on the animals who abounded on the wild soil, or on the fish of seas and rivers, and became himself wilder and harder hearted. The command of fire enabled him to overspread these new regions, and during an intermediate era he found it easiest to live by hunting and on tame cattle. Besides that, it was long difficult to protect crops; indeed, those who sow or plant must stay by their field till they gather the harvest. Inveterate custom fixes the diet of nations, and is deaf to argument, until stern necessity again comes in—as it assuredly must at last, if human population is to multiply. Thus, as evolution proceeds, it is discovered that flesh-eaters are struggling against a deep current of Nature, and must suffer, if they are obstinate, in the contest.

The Professor finishes his paper by discussing the vast amount of cruelty and suffering to animals incident to the present great use of butchers' meat.

Sunken Boilers Unnecessary.—No boiler need be lower than the return pipe, and the flow may be at the same level if required. Fix the boiler level with the return pipe; let the flow rise perpendicularly a few feet, say 5 or 6; then with a syphon bend bring it down to the same level as the return; it may then be carried to any distance without the least fear of the water not circulating quickly. I have a low greenhouse 140 feet long heated in this way with a No. 3 Tubular Boiler. The water circulates rapidly, and nothing could answer better, clearly showing that sunken boilers are unnecessary. A good sized air pipe should be inserted into the syphon.—W. WILLIAMS, Ryde.

Boiler Setting.—Referring to this question, I believe the advantages of having the boiler under its work have been over-rated. Judging from my own experience, it is not indispensable either for efficient or economical working. About four years ago, being unable to drain the stoke-hole, we lifted our largest boiler, so that its crown or top is now 18 inches above the main flow in the houses. I cannot see the slightest difference in its working, and the consumption of fuel is certainly not greater. I could point out other instances where the boiler is still higher, but the results are the same. In all cases where the boiler is thus raised, a 3-inch expansion pipe should be placed at the highest point and carried up vertically 8 or 9 feet.—E. HODDAR.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Potato Planting under Slight Protection.—Few crops are of more importance than the Potato crop, and means should therefore be taken to obtain it out-of-doors as early as possible; for, although Potatoes grown in pits and frames are very acceptable, still, unless brought on in such places very slowly, they are rarely equal in quality to those grown in the open air. If there exists a good south wall, this will, no doubt, be occupied with fruit trees; but, without in any way interfering with these, a row of Potatoes may be grown at the foot of the wall that will come in, with a little care, a fortnight earlier than they can be grown without protection, even in a sheltered border at a greater distance from the wall. Fork the ground over 15 inches wide from the wall, not going so deep as to injure the roots of the trees; and, if the soil be poor, add a little rotten manure; then open a trench 8 inches from the wall and about 4 inches deep, drawing the soil forward; take some of the Potatoes that a short time back were advised to be prepared by sprouting, reduce the sprouts on each tuber to two, and in planting cover them with the soil very carefully so as not to injure them; 9 inches will be far enough apart, as they will be taken up as soon as large enough for use. Where there does not exist a wall that can be taken advantage of in this way, a few square yards of a warm sunny border should be selected; this should have the assistance of a temporary frame made of light boards, with strips of wood nailed across, so as to admit of being covered at night with mats, when the crop appears above ground, which it will before spring frosts are over. Crops thus produced will be found to be well worth the labour bestowed on them, as Potatoes raised in this way will come in after those that have been grown in frames are used, and before those in the open ground that have received no protection. Potatoes and Radishes in frames will now be up, and must receive plenty of air on all occasions when it is not absolutely frosty, or they will become drawn. The lights should be raised at both ends for these crops, so as to let the plants have air equally all over.

Cucumbers.—Where a bed was made up for these in the beginning of the month, and the seed sown as soon as the bed was fit to receive it, the plants will now be coming up, and will require care during the cold winds of the ensuing month; keep them within a few inches of the glass, and place on both sides of the bed two feet in width of good hot dung, allowing it to come up the sides of the frame to within 6 inches of the top. Put a foot of litter at both the top and bottom. The side linings will impart fresh heat to the bed, and the litter will assist in keeping out the cold winds. The plants should receive a little air by raising the lights at the back half-an-inch or so every mild day. They will require slight shade when the sun is very bright. The principal bed to fruit them in should now be prepared, making it in every way (but larger) as directed for the bed in which the seedling plants were raised. Where advantage of a stove can be taken, the plants advised to be sown in January will now be in a fit condition for planting out. Three or four plants grown in boxes 2 feet by 3 feet, and 18 inches deep will, if well managed, produce through the season a very large quantity of Cucumbers. The best way to proceed will be to place two plants in each box, allowing one in each to bear a few fruit earlier than would be advisable for plants that were ultimately to bear on through the season; and when these earliest fruited plants have borne a few to cut them out; their space to be occupied by the others which were not allowed to fruit so soon.

Pruning Roses.—The time has now arrived when Roses will require attention as regards pruning. There is a considerable difference in the time when this necessary operation is performed by growers; the exhibitor of Roses prunes his plants at different times, so as to enable him to have a chance of the best blooms at the particular times at which he wishes to show them, for, upon early or late pruning, provided there is no mishap through spring frosts, will depend the time, in some measure, of flowering—thus, the earlier Roses are pruned the earlier they will bloom if not cut off by frost. But, for those who grow Roses, either to admire them on the plants, or with a view to being able to cut them in quantity, the principal consideration will obviously be to prune at the time that is most likely to ensure a plentiful harvest of flowers, independent, as far as possible, of spring frosts. Some allowance should be made between the south and north of the kingdom, as also between the localities that are dry and early, and others that are damp, low, and subject to late spring frosts; if not pruned until very late, say April, the growth, which will have then made considerable progress at the extremity of the shoots, is so much of the energies of the plants wasted. The best time for pruning in general may be set down as the first days in March for the more favoured parts of the country, with the middle of the month for such as labour under local disadvantages of climate. I have known some amateurs so impatient to

have their Roses pruned early, so as to present a trim appearance, that they could not bear to see them left longer than the end of January; the result was, that year after year, the first, and by far the best flowers, were all cut off; yet, it never seemed to occur to them that it was the early pruning that was the cause. As to the extent to which Roses should be pruned, that is altogether dependent upon the strength of the variety; a plant of a given size of any strong-growing kind will most likely be able to make a dozen and a half of strong vigorous shoots, each bearing a goodly bunch of flowers, whereas a plant of a similar age, but a weak grower, will not, perhaps, be able to make four or half a dozen shoots strong enough to bloom; consequently the strong-growing sort will require pruning so as to allow it to form a score or so of shoots, whilst three or four will be enough for the weakly grower. This, I am aware, is opposed to the old theory of Rose pruning, but it is not opposed to a common-sense view of the matter. But I would say to the amateur, Do not grow these delicate, and, for your purpose, worthless weak Roses; and if you select the varieties you grow from the exhibition stage, you are sure to have a good sprinkling of these weak sorts. The object of the amateur is to get a quantity of beautiful flowers, and not to grow half a dozen plants of one kind, however excellent the individual blooms may be, even if from the half-dozen plants he only obtains as many flowers in a season. Thus it will be seen that the extent of pruning to which each tree or bush is subjected must be regulated by the natural strength of growth of the variety; the shoots that are allowed to remain may be cut back to three or four eyes, and all others cut clean out from the base where they spring, not in their case leaving so much as a single eye, as the object is to direct all the energy of the trees into the flowering shoots.

Glass Structures.—In the stove the generality of plants may now be potted; such as *Eucharis amazonica*, *Francisceas*, *Gardenias*, *Aphelandras*, *Ardiasias*, *Cyrtanthera magnifica*, *Eranthemums*, *Vincas*, *Torencias*, *Ixoras*, *Plumbago rosea*, *Pentas carnea*, the white-bracted *Mussaenda frondosa*, *Begonias*, *Alocasias*, *Caladiums*, *Anthuriums*, *Crotons*, *Dracenas*, *Marantas*, *Aralias*, &c., giving them pots proportionate in size to the requirements of the individual plants or the size it may in each case be advisable to grow them to. A good-sized stove plant of most kinds may be grown in a moderate-sized pot, especially if assisted through its most active growth with manure-water. Where there exist Vines in bearing condition that were pruned, and that received their winter dressing at the time advised, these should now be encouraged to push, by keeping the house close, with little air admitted; but this must not be attempted yet for some weeks, if it is simply a cold Vinery, without any heating apparatus, as in that case there might be danger to the young shoots, when just "broken," from the severe frosts we frequently get at the end of April.

A VINE AND PEACH TREE DESTROYER.

(OTIORHYNCHUS SULCATUS.)

AMONGST the numerous insects which annoy and trouble the cultivator, there is perhaps none so injurious and difficult to combat as this. Though classed with beetles, I believe the hard wing cases of these weevils are joined together, and do not cover true wings; at least I have failed to find any, and believe they never fly. But I am more acquainted with their habits than with their anatomy. Nothing is to me more surprising than that an insect which travels so slowly, and appears unable to fly, can find its way with such unerring instinct to the plants upon which it feeds. Perhaps the solution is that they are very numerous, and will feed on a great variety of plants. Of one thing I am quite sure, that many cultivators attribute the mischief caused by the grub of this weevil to the wire worm. The wire worm is injurious enough to Carnations, Pinks, Daisies, many of the Grasses, Carrots, Potatoes, and perhaps other culinary vegetables; but I never in my life saw the root of any tree or shrub touched by them, and should not care if there were a hundred thousand in my Vine border, provided they did not leave it for any other pasture. The grub of the *Otiorynchus*, which is white, and shorter and fatter than the wire worms (which are yellow, and, as their name implies, tougher), is a much more general feeder. There is little doubt they feed on the roots of Grasses, because I detect them at times in turf soils just brought from the field. They will be found at the roots of Yew trees, the small fibres of which are a very favourite food with them; and where Yews abound these insects are generally plentiful, but, as old Yew trees make such an immense mass of roots, they seldom or never appear to suffer from their attacks. But amongst a lot of seedling Yews the effect is very different, for fond as these pests are of Yew roots, they much prefer the young stem of a seedling Yew just below the surface of the ground; and, as they remove all the bark down to the hard wood, of course the plant is killed. In the same way they attack young *Rhododendrons* and *Azaleas*, and

many nurserymen have lost thousands of young plants from this cause, whilst the injury to older and established plants is generally trifling, as they never eat the stem of an old plant, though in light peaty soils they are sometimes numerous enough to injure even large plants by eating the roots. In the same way young Vines are often destroyed whilst in small pots, though I never knew an established plant suffer from their attacks. They are also very destructive to young *Camellias*, many plants being lost by the injury of the bark just under the soil; but as these plants do not at once show the effect of the damage, the cause is often not detected. Before the leaves of a *Camellia* change colour, the stem has had time to turn brown, and it is not easy to see the bark has been removed below the soil without careful scrutiny. It will be seen from these remarks that nurserymen are greater sufferers from the depredations of these insects than any other class of cultivators, because young and tender plants are what they chiefly affect. I know no instance in which they attack the stems of old plants, though I have known the roots of Peach trees injured. So little are the habits of insects studied by those most interested, that I have known men who have suffered severely who had never recognised their enemies; others who have known to their cost the grubs or larvae, and called them ringers, from their habit of ringing or removing the bark from the stems of plants, yet had no idea what insect they turned to when in the perfect state. The grubs of the Click Beetle, known as wire-worms, remain in the larva state three years, which accounts for the great injury sustained by many who cultivate fresh broken-up turf soil for two or three seasons, but the *Otiorynchus* grub turns into a beetle the following season as soon as warm weather comes. A little before it changes, the grub, which was white, with a head of a slight yellowish colour, has almost a black head. The beetle is of a dark colour, almost black, with the wing cases corrugated or furrowed. It is a night feeder, and is generally at rest and hidden during the day. It feeds on the leaves of the Peach, Vine, Fig, *Camellia*, Orange, *Rhododendron*, and many other trees; and where such leaves are seen to be eaten on the edges they should be examined by candle-light, and the beetles destroyed. Care must be taken not to shake the trees, as the insects will fall to the ground, and remain so entirely without motion as to be very difficult to find, unless a sheet be spread on the ground to catch them. There is one kind of mischief these insects effect I had forgotten to mention, and yet it is often very serious to young trees. Thorns, Purple Beech, standard Briars, &c., when fresh planted, will, if the spring be very dry and warm often die in large numbers, and yet many of them, if unmolested, would probably have lived. If they are carefully examined, it will be found that the buds have been eaten out, or eaten round, at the base of the bud. On examining such trees at night, this and a smaller brown weevil will be found at work in large numbers. It appears that plants in ill health, or struggling for life, are like unhealthy animals, a favourite food for insect pests. I have now given you an account of all I know of this insect plague, and if others of your numerous readers can add to the information I shall be much obliged to them for any additional facts, particularly if anything is known of the rate of increase. The number of grubs found in hot-houses, where few or no beetles have been previously seen, would lead one to believe they must lay a great number of eggs, but I have never detected where or how they are deposited. One fact of interest I had forgotten—the toad appears one of its greatest enemies, and devours them whenever the opportunity is afforded it.

Chilwell.

HOME-GROWN TOBACCO FOR PURPOSES OF FUMIGATION.

I WAS surprised to see (p. 168) the merits of home-grown Tobacco for fumigating purposes so much underrated as to be compared with "common brown paper." I do not know what it may be like in the north, but in the west and east of England I have grown it, and seen it grown, for fumigating purposes for many years, and always found it far superior to ordinary tobacco-paper if properly attended to and harvested. Your correspondent must, I think, have grown one of the thick, sappy-leaved varieties instead of that best suited to the purpose in question, and, if so, his failure may be accounted for. The variety I grow, and would recommend for the purpose, is *Nicotiana virginica*. This, when well grown, has leaves from 2 feet to 2 feet 6 inches long, and 6 to 9 inches wide. All the other varieties I have seen have rounder leaves with large, raised, succulent-looking veins. They are more difficult to dry than *virginica*, and, when dried, are much less pungent and useful for fumigating. I do not suppose that Tobacco grown in this climate contains anything like the amount of essential oil to be found in the leaves of plants grown in more southern latitudes; but, that they contain sufficient to be more destructive to greenfly and thrips, weight for weight, than tobacco-paper, I have

J. R. P.

proved over and over again. The great thing is to grow the plant well, so as to get all the leaves to their full size and properly matured before harvesting them. To do this, there should only be eight or nine of the main leaves allowed to remain on a stalk, as the lateral leaves and those towards the top have not time to come to perfection, and are thin, sappy, and useless. As soon, therefore, as the plant has formed that number of leaves, it should be stopped, and any growth that may show afterwards at the axils of their leaves should be removed, so as to throw the whole energy and strength of the plant into those remaining. The plants should not be allowed to flower to a greater extent than is necessary for the purpose of bearing seed, should it be required for supplying plants for the following year. The seeds should be sown in heat towards the end of April, and as soon as the plants are large enough to handle they should either be pricked out, or potted singly in small pots, in light rich soil, to be nursed on in gentle heat till the end of May. They should then be gradually hardened off for planting out early in June. An open sunny situation should be chosen for growing them, and the ground should be properly prepared by trenching or deep digging, working in, at the same time, a good dressing of rotten manure. The plants should be planted in rows 1 yard apart, and 2 feet from each other; and as they progress in growth they should be staked singly, or, if stakes are scarce, they may be placed at wide intervals, with a strong one at each end of the row to which to strain a piece of stout string or tar yarn, and to this the plants may be tied. While growing, they will be greatly benefited by receiving a good soaking or two of manure-water, and care should be taken that they do not receive a check at any time, or the leaves will not attain a large size. When of full size, and properly matured, they should be gathered and hung on nails in a dry open airy shed, or threaded on string and hung in the same situation. If placed in the sun or dried too quickly, the leaves crumble to pieces, and the Tobacco loses a good deal of its strength. As soon as they are properly dry, they should be packed away in boxes, and stored in a dry place to keep them from getting mouldy. During the process of packing, some very fine powdered saltpetre may be shaken in amongst the leaves, in the proportion of 1 oz. to 20 lb. of leaves. This will make them smoulder away in the fumigating pot, and add to their effect in destroying insects. In smoking, make choice of a still damp night for the operation, as the laps of the glass are then filled with water, and the house is comparatively air-tight. Repeat the operation early the following morning while the insects are weak, and before they have time to recover through the admission of air to the houses, as this has a revivifying effect on them. Syringe immediately after to wash off stragglers and refresh the plants.

J. SHEPPARD.

Grafting Cabbages.—A correspondent of the "Gardeners' Record" states he has grafted Cabbages successfully. For this purpose I made choice, he says, of two varieties of the Cabbage—Enfield Market as the stock, and the Red Dutch as the graft, choosing the darkest plant that my seed bed then afforded. The grafting was performed at the end of April, 1872; they united very freely, and the scion grew very luxuriantly. It is well known that, under ordinary circumstances, each of these Cabbages produces very close, firm heads, but in this case the graft showed no inclination to do so; it remained open, with a slightly apparent dash of stock blood. At the end of spring, 1873, it threw up a very strong, straggling, flowering stem, from 7 feet to 8 feet in height, the individual flowers being particularly large, but by no means abundant; consequently the quantity of seed ripened was not large. During the first week of February, 1874, a portion of the seed was sown, the result of which is that I have obtained a somewhat interesting lot of Cabbages, Kale plants (very dark and curled, nearly, if not altogether, as dark as such as Dell's and Belvoir Castle Beet), Savoys, and Red Cabbage, a considerable number partaking of the character of the stock family. Although imbued with the blood of the graft, that of the stock predominates in the majority of cases, and, strange to say, all the progeny appear to be more or less deficient of the tendency to Cabbage.

PERSONAL.

MR. JOHN SHERRATT is about to remove to his new Knypersley Nursery, in which he has built several Orchid and other houses, and ventilated them on Richardson's system.—Mr. Farr, late of Owlpen Park, Gloucestershire, is about to take the management of Sir Rainald Knightley's gardens at Fawsley, near Daventry; and Mr. Shepherd, formerly of Lytham Hall, Lancashire, succeeds Mr. Wicks in the management of the gardens of Mrs. Kemble, Vellore, near Bath.—Mr. Lascelles, of Bunhill Row, Finsbury, is just completing an order from the London School Board for 11,000 pitch-pine desks and seats for their new schools. Mr. Holloway has also given him instructions to prepare the wood-work for his Sanatorium, which is to be completed in six months, at a cost of £10,000.

NOTES AND QUESTIONS—VARIOUS.

[Many notes and answers, obligingly sent us by correspondents, are unavoidably omitted this week from want of room.]

Flowering Time of the Snowflake (*Leucojum vernum*).—Mr. Niven, in his notice of this interesting flower, says that it flowers a month later than the Snowdrop, i.e., about the middle of March. Here, in the south-west of Scotland, it opened its first blossom on the 13th of February—this year in a north border. Snowdrops were very late this year, and were then, and continue to be, in great beauty.—SALMONCERS.

Burnell's Alexandra White Cos Lettuce.—This (see p. 154) is misnamed Williams's Alexandra White Cos. I can corroborate Mr. Burnell's statement that it is the best of Cos Lettuces for summer use.—R. BAXBOW, *Wimbledon*.

The New Conical-fruited Solanum.—This has been named, we observe, by Messrs E. G. Henderson, *Solanum hybridum Hendersoni*. So very productive is it that upon one plant alone, scarcely 18 inches in height, as many as 200 fruits were counted.

Aloes now in Flower at Sudbury House, Hammersmith.—*A. ciliaris*, *A. Salm Dyckiana*, *A. fruticosa*, *A. humilis*, *A. variegata*, *A. Cooperii*, and *A. plicatilis*. We have also a fine *Agave*, not before seen in flower, starting; it has grown 4 feet in one month. *A. squidenis* also shows signs of flowering, as does likewise *A. Bessereriana hystrix*.—J. CROUCHER.

Coronilla glauca and Heliotropes as Winter-flowering Plants.—In a lean-to greenhouse, heated by a flow and return pipe, I have a *Coronilla glauca* trained to the back wall, and I know of nothing more beautiful than it is, or more useful for cut flowers. It has been in bloom since November, and is still full of flowers. The *Heliotrope*, too, is equally useful.—A. MACFARLANE, *Great Tew, Easton*.

Prizes for New Peas.—Mr. Laxton, of Stamford, offers thirty guineas in prizes for Peas grown from seeds of kinds raised by him. The highest prize is £4, there are two of £3, two of £2, twelve of £1, and ten of 10s. each. The competition is to take place at the Midland Counties Grand Horticultural show at Birmingham, on the 1st, 2nd, 3rd, and 5th July, and on the occasion of the Royal Horticultural Society's Rose show at South Kensington, on the 7th of the same month.

Compton's Surprise Potato.—This is a coarse-looking purple-skinned Potato, with somewhat sunken eyes; it is flattish, long in shape, but has firm white flesh. It keeps well, and makes a capital Potato for the spring months, when the earlier sorts are exhausted. As it is a robust grower, and will produce tubers of great size, it should be grown in rather poor soil, where it will always yield a large crop. It resembles the old Jersey Blue, but is a heavier cropper.—A. D.

Major Clarke's Solid Red Celery.—I have long grown the Sulham Prize, Sandringham, and several other kinds of Celery, red and white, and I am of opinion that Major Clarke's is undoubtedly the best of the red varieties. In flavour it is unsurpassed, and it is remarkably firm, solid, and brittle; even the outer leaves are thicker in proportion to the length than those of most other kinds. It is very hardy, and it is very rare to meet with a soft or pithy plant of it. In short, it is altogether a first-rate Celery.—J. E.

Drying off Bulbs.—Allow me to bear testimony to the soundness of "J. S. W.'s" advice with regard to keeping *Caladiums* moderately moist during winter. The same advice is equally applicable to watering *Gloxinias*, &c., which, if dried off suddenly and kept in a high temperature, are likely to disappear entirely. Not only do stove bulbous plants suffer from being dried off, but even hardy and half-hardy ones as well. Those who force many *Hyacinths* might reduce expenses next autumn by attention in this respect.—R. P. B.

Hardy Autumn Flowering Plants.—I have two long borders planted with standard Roses, Japan Lilies, *Gladioli*, *Phloxes*, *Antirrhinums*, and *Pentstemons*. What else can I add to bloom in autumn?—W. T. C. [*Anemone japonica*, and its varieties, *Asters*, *Chrysanthemums*, *Larkspurs*, *Fuchsias gracilis*, *Gaura Lindheimeri*, *Helianthus multiflorus*, fl.-pl., *Lupins*, *Knoshera Lamarckiana*, *Platycodon autumnale*, *Schizostylis coccinea*, *Tritoma Uvaria*, *Veronica Andersoni*, autumn *Crocuses*, *Colchicums*, *Sternbergia lutea*, and many others. See page 233 of "Hardy Flowers," where a long list of the best hardy autumnal flowers is given.]

Centradenia rosea.—The old *Centradenia rosea* is a very charming little plant of pendulous growth, with light rose coloured flowers, and might be used more than it is for general decoration. Owing to the smallness of its leaves, it grows into a dense wavy voluminous mass—a habit much needed in giving effect to other plants. This little Mexican *Melastomad* is easily grown and increased by means of cuttings in spring, which strike freely, and by potting on in summer and growing them in a temperate place with plenty of moisture, they thrive and make beautiful plants by autumn. They are not particular as to soil—provided it be free and open. They will thrive in almost any mixture, but I prefer two parts loam and one of river sand, and small pots.—CHEVALIER.

Large Scotch Firs.—The remarks recently made in your columns respecting these trees lead me to again mention a remarkably fine specimen of the Scotch Fir that stands in one corner of the estate of the Right Hon. Wm. Cowper-Temple, at Nursling, near Romsey, Hants. I much doubt whether there is a finer or, indeed, a handsomer tree of its kind anywhere in the south of England. It is some eight years since I last saw it, but then, when attempted to be enclosed within the arms of two tall full-grown men, chest high, there was still about 18 inches to be encompassed. This would make its girth at 5 feet from the ground to have then been 13½ feet; probably by this time it is 14 feet in circumference. The stem, to a height of about 30 feet, is remarkably clean and smooth, and it has a fine rounded healthy head.—A. D.

The Orange-milk (or Red-milk) Agaric (*Lactarius deliciosus*).—Can you give me any information respecting the red-tinted Fungus found in Pine forests, and which is said to be superior in flavour to even the common Mushroom, as its specific *deliciosus* would indicate. A neighbour of mine, who has several Fir plantations, would be glad to know what steps he ought to take to introduce this Fungus into them.—CHARLES BOYS. [This Agaric is by no means uncommon. It grows under the drip of Scotch Fir trees, and may almost always be found at the proper season where these trees abound—that is in September and October. There is no fear of mistaking this Fungus with ordinary care. Its cap is of a dull rufous orange colour, turning pale when growing in situations exposed to light, with narrow concentric circles or zones of a deeper hue. It is the only Agaric which yields an orange-red milk when cut or broken, and which turns a dull green an hour or two after being bruised. When you have found it we will tell you how to cook it; you will be sure to find it in the line of drip from Scotch Fir trees growing in open Grassy situations. There are many other red-tinted Funguses growing under Fir trees, but this only is safely to be recognised by ordinary observers. Try the effect of introducing the mycelium or spawn into your neighbour's plantation.]

No. 178.]

SATURDAY, MARCH 6, 1875.

[Vol. VII.]

"This is an art
Which does mend nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE GIANT LILY NEAR LONDON.

IN compliance with your request, I forward the following note in reference to this Lily. The soil of my garden, like that of the rise of East Sheen continued into Richmond Park, is a gravel of a good binding sort, excellent for the walks. It rests upon "London clay." The depth of the gravel with me is from 10 feet to 16 feet, and affords good drainage to the beds; but, for any special growth, loam and bog-earth must be added. The gravel was removed, in 1860, to a depth of 8 or 10 feet, and many loads of bog-earth, with some loam and a little lime, were put in to receive the Rhododendrons and Azaleas in the round "Rhododendron bed" on the lawn. In May, 1872, I planted three bulbs of *Lilium giganteum* in three of the interspaces of the Rhododendron bushes, which spaces had the best aspect in regard to sunshine. Silver sand, as usual, was put about each bulb, set at the depth of 6 inches, in the above soil, with the addition of old leaf mould, which had been rotted with occasional drenchings of dilute liquid manure. There was a feeble sign of growth in the autumn of 1872, and the bulbs were protected through the winter of 1872 and 1873 by a light covering of dried Fern. In May, 1873, three of the leaves began to rise, and diverge from each bulb. They were carefully protected from occasional frosts, but no flower-stem was developed this summer. After similar winter and spring treatment (as against frosty nights in May), a grander spread of the fine broad, bright, glossy, leaves appeared; and, in June, 1874, I occasionally gave the Lilies dilute liquid manure. From one only of the three did the magnificent columnar flower-stem, 2 inches thick, spring up to the height of 6½ feet, which became crowned with nine flower-buds, the first of which opened on the 2nd of July, lasting to the 9th, and the others in succession, with a like period of bloom. A broad band of violet contrasted with the enamelled whiteness of each gracefully recurved petal; and as one sauntered over the lawn in the vicinity of the large clustered flowers, their delicate perfume, diffused through the summer air, added to the pleasure. They formed seed-pods, 3 inches long by 1½ inch diameter. Whether the seeds, ripened in the open air and gathered in October, will sprout, the experience of the coming months will decide. In the event of this attempt to fulfil your wish meeting the eye of the "Correspondent at Ipswich," who, after the notice in *THE GARDEN* last year, wrote to me on the subject, I regret to say that his letter became mislaid;

and, if he will again favour me with his name and address, his wish will be attended to. I am in hopes that the two bulbs, which developed only leaves last summer, may give us flowers in the ensuing one, and shall be grateful for any hint from more experienced floriculturists.
RICHARD OWEN.

TREES IN WINTER.

I HAVE often thought that this subject, to which Mr. McNab refers (see p. 147), ought to receive more attention from landscape

gardeners, and planters generally, than it does at present. The individuality of different ornamental trees is much more apparent in winter than in summer. When clothed with foliage, we lose all the character and variety noticeable in the arrangement of their branches and twigs, which is very distinct in different species. One of the most obvious features in connection with the wintry aspect of trees is their tone or colour. The common Elm, for example, stands out nearly black when seen against a clear grey sky, or when snow is lying on the ground; and the same may be said of the common Hawthorn. Oaks are a little more cheerful in tone, and Poplars still more so, as their growth is more pliant. A Poplar, when swayed to and fro on a bright winter's day is one of the most beautiful of all trees, because then the different shades of soft silvery-grey and brown are reflected from the branches in a very pleasing manner. Poplars are always in motion, too, whenever there is the slightest breeze, and this gives variety and interest to the groups of other trees in which they are planted. They are very attractive when budding out in the spring, which some of them do very early; and their green shades, being very delicate, harmonise thoroughly with the soft browns of the stem and branches. One of the lightest and brightest of all trees in the winter, however, is, undoubtedly the common Birch, which should always find a place on the lawn, and especially in the vicinity of ornamental water. Seen on a bright sunny day in December, the Silvery Birch is one of the most beautiful of all ornamental trees, and when covered with white hoar-frost, it is difficult to imagine a more attractive object. The Wych Elm and Larch are also beautiful under the circumstances just named. The Larch, when planted as an isolated specimen on the lawn, is most effective, and very different from the same tree when drawn up in a mixed plantation. As a solitary specimen it varies in height from 50 to 100 feet; and its light drooping branches feather down to the turf in the most graceful manner; no ornamental tree is more beautiful in the early spring months, when its young foliage shows the most fresh and delicate shade of green imaginable. The common Ash is a bright-looking tree in winter, the bark being of a silvery-

The Giant Lily (*Lilium giganteum*).

grey, or light brown tint. This tree ought to be more generally planted in the suburbs than it is; for, as a town tree, it is immeasurably superior to either Elm, Lime, or Chestnut, all of which suffer from drought and red-spider during hot summers, and lose their leaves or become rusty towards the end of July. The Ash is rather late in leafing, but, like the Planes, its foliage keeps fresh and green, until the sharp frosts of autumn cause it to fall; and, on this account, it deserves a place in town squares and gardens. B.

NOTES OF THE WEEK.

— BULBS of *Narcissus monophyllus*, received from Algeria by post, have just flowered in the Rev. M. J. Berkeley's garden, at Sibbertoft. This Daffodil has previously flowered at Kew, and appears to be a somewhat variable plant. Mr. Berkeley states, that the flowers produced at Sibbertoft are much smaller, and of a purer white than those of the Kew specimens, and we have ourselves observed the same peculiarity in the flowers of this variety produced by bulbs received from Algeria by Mr. Giles Munby.

— THE rare and distinct *Miltonia caneata* is now flowering freely in Mr. Peacock's collection at Hammersmith. In habit it resembles *M. Clowesii*, and bears from four to six flowers on a scape. Its greenish sepals and petals are crisped or undulated, and conspicuously blotched with blackish-brown. The wedge-shaped lip, which is about an inch across, is of snowy whiteness, and contrasts strikingly with the other divisions of the flower.

— AN evidently careful observer, writing in the "Botaniska Notiser," shows good reason to doubt recent statements that leaves of *Drosera* eat flesh. "That the meat mostly disappears when it becomes rotten is not very surprising; the *Bacteria* consume it; but that the leaf has absorbed it through the cells of the glands, whose contents are contracted and dead, must be considered to be out of the question."

— THE south side of Covent Garden Market has now been roofed with glass, which not only protects the stalls and their produce from the ill effects of exposure, but has improved the appearance of that side of the market. The new roof is about 220 feet long by 60 feet wide, and has an extreme height from the market level of 60 feet. It is curvilinear, the span being carried on iron ribs, springing from columns on each side. The upright sides of a lantern, which runs the whole length of the roof, has been left open for ventilation, for which ample means have also been provided elsewhere; and the whole structure has a light and cheerful aspect. Let us hope that other parts of the market still unprotected may receive similar attention.

— IT may interest lovers of curious plants to know that Mr. Elwes has now in flower the following species of Terrestrial Orchids, viz., *Ophrys fusca*, *O. Speculum*, *O. tricolor*, *O. Scolopax*, and *O. aranifera* var. *specularia*. *Speculum* and *tricolor* are among the most beautiful of all the European sorts, while the variety of *aranifera*, called *specularia*, is a large and handsome species, and very variable. *Neotinea intacta*, the plant lately discovered in Ireland, is also in bloom; it is curious, but not showy. These were all in a cold frame during the summer and autumn, and were moved into a greenhouse just before Christmas. Many other species are showing their flower-spikes, and will be in bloom as soon as the sun, which has hardly made its appearance this year, comes out again.

— MR. WM. FALCONER, writing to us from Rosedale Nurseries, Brenham, Texas, says, "horticulture is very backward here; true, I saw one little greenhouse at Galveston and another at Houston, and a few Oranges, Oleanders, and such things, in the gardens; but, in country places, poultry and pigs reign supreme where Daffodils and other flowers ought to grow. With respect to vegetables, the people seem peculiarly negligent, and can in no way be compared, as regards industry in this direction, with the New Englanders. Just now, all we possess in the way of culinary produce are Sweet Potatoes and Shallots, whereas 'up north' they have Potatoes, Cabbages, Squashes, Turnips, Carrots, and other roots in the cellars, besides quantities of Tomatoes, berries of many kinds, Pears, and barrels upon barrels of Apples. Here very inferior Apples cost from 10 to 20 cents a-piece."

— THE March number of the "Botanical Magazine" contains coloured plates of the following plants:—*Gustavia gracillima*, a very showy Myrtaceous shrub, collected by Roezl in New Granada, and sent by him to Mr. W. Bull. Its lanceolate serrate deep green leaves are a foot or more in length, whilst its great single Rose-like flowers are 5 inches in diameter, and have a thick green purple-rayed disc in the centre. *Masdevallia Chimæra*, a singular Orchid, having spatulate fleshy foliage, and yellow-crimson spotted hairy flowers. Its sepaline tails are 3 or 4 inches in length, and of a clear reddish-crimson, or blood, colour. *Colchicum luteum*; this is the only yellow *Colchicum* at present known. It comes from the mountainous ranges to the west of India, where it grows at 6,000 or 7,000 feet elevation. The flowers are little more than an inch across, but the colour is bright and effective. *Theropogon pallidus*, a pretty little grassy-leaved Liliaceous plant, with many-flowered scapes, which, at first sight, remind one of pink-flowered scapes of Lily of the Valley. It is nearly related to *Ophiopogon*, but is readily distinguishable by having deciduous foliage. *Wahlenbergia tuberosa*, a pretty little bell-flower, with a tuberous root stock, and slender stems of white pink-striped

flowers. It is a native of Juan Fernandez, whence Messrs. Veitch and Sons received it from their collector, Mr. Downton.

— A NEW edition, with many additional illustrations, of "Alpine Flowers for English gardens" is in preparation and will be ready in the spring.

— THE rare and beautiful *Phalænopsis intermedia* is now in flower in Mr. Bull's collection at Chelsea. Its sepals and petals are white, shaded with lilac, and the lip is of a rich lilac-purple colour. It is a native of Manilla.

— THE collections of *Camellias*, *Phalænopsis*, and *Nepenthes*, in the Royal Exotic Nursery at Chelsea, are now in excellent condition and well worth a visit. The *Camellias* and *Phalænopsis* especially are flowering in the greatest profusion, and are in the best possible health and vigour.

— M. CARRIERE, writing in the "Revue Horticole," gives a remarkable instance of the vitality of a *Chionanthus* bud which, nearly sixteen years ago, was inserted in the Flowering Ash (*Fraxinus Ornus*), and which has sent out a vigorous shoot that is growing rapidly and strongly. An illustration of it is given in the "Revue."

— AS an example of the enormous scale upon which the cultivation of fruit trees is carried on in the United States, it may be mentioned that a recent State return shows that, in 1873, 334,067 acres in Illinois alone were occupied by orchards; while according to a Blue Book return, published a short time since, the orchards of Great Britain only covered 150,526 acres, being less than half the return for one American state.

— WE have received fresh blooms of *Oncidium* (*Odontoglossum*) *platyodon*, now flowering for the first time in this country—so far as we are aware—from Sir William Marriott's collection at Down House, Blandford. The plant is of robust habit, and the flowers which measure about an inch across, are of a clear yellow colour, and quite distinct from those of any other species with which we are acquainted.

— FROM the superintendent's report (1874), it appears that the Royal Botanic Gardens, Calcutta, are recovering very slowly from the devastating effects of the cyclones of 1864 and 1867. The growth of the shrubs and trees planted to replace those uprooted has not been very luxuriant, and a long time must elapse before the welcome and useful shade of noble trees, such as once filled the garden, will be enjoyed there again.

— THE South Park Commissioners of Chicago have recently determined upon the establishment of botanical gardens in the park, and have set apart for the purpose a tract of 60 acres, to which additions will be made from time to time, as occasion may require. A botanical museum and herbarium will be included in the scheme. A circular has been issued by the board of managers, soliciting contributions from kindred institutions. The works are to be commenced as soon as the weather will permit.

— AN International Horticultural Exhibition will be opened at Cologne on the 25th of August next, under the patronage of the German Empress and the Crown Prince. The general committee has issued a circular, inviting all who take an interest in the progress of horticulture to contribute to it. The Exhibition is to comprise all horticultural productions (with the exception of wines and Grapes, which are excluded, owing to the possibility of introducing the *Phylloxera*); also tools, machinery, glasshouses, as well as collections of any kind connected with rural life and the development of garden culture.

— MR. TILLERY states that, for the last week the weather in Nottinghamshire has been very winterly, the thermometer ranging from 33° to 35° in the shade. On the morning of the 25th ult. the ground was covered with snow to the depth of nearly 6 inches, but it melted away next day, and sleet showers have been falling since with an intensely cold wind from the north-east. The Apricot and Peach bloom is yet safe, owing to its not being fully expanded; and, should the cold weather last a week or two longer, there will be all the better chance of its setting well. There is an excellent show of fruit buds on all kinds of hardy fruit trees, the past warm summer having ripened the wood well.

— A FRUITING BRANCH of the Chinese Kumquat (*Citrus japonica*), bearing fifty-six fruits, was exhibited at the last meeting of the Royal Horticultural Society by Mr. Sherratt, nurseryman, at Knypersley, Cheshire. The Kumquat, which is one of the most prolific of all the Orange tribe, bears golden-yellow fruit, about the size of a pigeon's egg. It may be propagated from seeds, but, in order to fruit it successfully it should be grafted on *Limonia trifoliata* as a stock. Mr. Fortune, who is well acquainted with this plant both in China and Japan, informs us that it would doubtless succeed out of doors in some of the warmer parts of this country, but that, to fruit it successfully, it requires a warm greenhouse temperature during the summer months. Apart, however, from its delicately perfumed fruit, the plant deserves culture as an ornamental plant.

THE GARDEN IN THE HOUSE.

A BUTTON-HOLE BOUQUET FOR MARCH.

PASSING through Covent Garden Market a few days ago, I was so much struck with the beauty and simplicity of a coat bouquet in Mr. Dickson's shop, that I send it to you for illustration. It is made up of a leaf of Lily of the Valley at the back, upon which lies one spray of that flower, mixed with four or five very small pieces of Maiden-hair Fern. These portions of a frond are so arranged that they break the hard outline of the leaf behind them, and also tone down its bright green by their glaucous shade of colour. In front of these are placed a fine thick-petalled bud of Climbing Devonians Rose. This, of course, has been properly wired, and slightly blown open. The base of the bud is concealed by two well-chosen leaves from a Fairy Rose, by which means another shade of green is introduced into the bouquet, which not only serves to set off the Rose-bud to the best advantage, but also contrasts well with the foliage previously used. These contrasts, too, are not merely variations in shade of green; their importance depends still more upon the contrasts in their form, than which it would be difficult to select three differing more widely. This bouquet, which, at this early period of the year, is a good

A Button-hole Bouquet for March.

specimen of what horticulture can do in furnishing us with valuable flowers in advance of their natural period of blooming, may be arranged two or three months hence from plants growing out-of-doors, the Maiden-hair excepted. And, even if it were a necessity that hardy plants only were to be employed in making up this button-hole bouquet, some well-selected leaves from *Thalictrum minus* would prove such an efficient substitute for the Maiden-hair fronds that ninety-nine people out of a hundred would regard it as a Fern, and not as a leaf from a flowering plant. Those who do not possess means for growing *Adiantum cuneatum* are strongly recommended to cultivate this hardy apetalous British Ranunculaceous plant, which does best in a calcareous or magnesian soil. W. T. P.

A Useful Palm Seed.—Richardson, in his African travels in the Great Desert, vol. 24, p. 323, says, "Dates are not only the principal growth of the Fezzan oases, but the main support of their inhabitants. All live on Dates—men, women, and children, and even the lower animals." New Dates called *rubeb*, will last an Arab for two months during summer, and during the rest of the year he uses the hard pressed fruit, called *adjone*. The fleshy part of Dates contains according to Remsch, 58 per cent. of sugar accompanied by pectin, gum, &c. Dates, especially when dried, are very nutritious.

VARIOUS BULBS FOR INDOOR DECORATION.

Amaryllis.—The various species of *Amaryllis* are, with few exceptions, natives of warm latitudes; and, therefore, are in a high degree suitable plants for the window of a heated room, in which they thrive remarkably well, even when not placed in a very sunny position, and produce in abundance their large, bell-shaped, red, or red striped with white, or white striped with red, flowers, which grow in umbels on strong stems. The following large-flowered kinds are the best for winter flowering:—*A. aulica*, a Brazilian species, the flowers of which are large and showy; they are of a deep red colour, the petals being veined with a deeper tinge and tipped with green, and open between October and March. It is from this species, hybridised with *A. vittata* and its numerous varieties, that M. Van Houtte, of Ghent, has raised the fine large-flowered *Amaryllises* now so well known. *A. equestris*, a native of tropical America, has light brick-red flowers. *A. Reginae*, a native of Central America and the West Indies, has dark red flowers, which usually have a lighter-coloured streak down the middle of each petal. *A. rutila*, a native of Brazil, has flowers of various shades of red. Allied to this is the species known as *A. reticulata*. *A. vittata*, a native of tropical America, has white flowers, with three red longitudinal streaks on each petal. These kinds are almost exclusively the parents of the wonderfully numerous garden varieties that are now in cultivation. One of the first hybrids raised from them was the well-known *A. Johnsoni*, the offspring of *A. Reginae* and *A. vittata*. This has deep red flowers with a white streak down the middle of each petal. By continued crossing, not only a great variety of forms with variously-marked flowers have been produced, but many intermediate varieties have also arisen which unite all the characters of the original parents in various shades and gradations of resemblance. In bringing them into flower in winter, two modes of culture are employed, and as they are almost equally good, we shall describe them separately. In the first mode, the bulbs should be potted in a mixture of two parts loose loamy soil and one part of leaf-mould, adding a little sand. The pots should then be placed in a window of the heated room. They should be watered all the year round with lukewarm water as often as they become dry, and, treated in this way, they will bloom, according to their kinds, in October and November, or from March to May. After flowering, the supply of water should be gradually diminished, and in about six weeks they should be transplanted. In doing this, the young bulbs should be removed, but the bulbs should only be loosened with a pointed piece of wood, and the roots should not be disturbed, but any that are decayed should be cut away. After transplanting, they should be watered whenever the soil becomes dry; and, if the plants are healthy, they should receive a little liquid manure from time to time, to strengthen the bulbs for winter-flowering. They may be transplanted either annually, or every two years. Under this treatment, we have seen plants of *Amaryllis* blooming every year in a warm room as finely and as strongly as in a plant-house, and showing handsome healthy leaves all the year through. This method, however, has one drawback in this respect, that one cannot be quite sure whether the plants which are treated in this way will bloom during the winter months, or not until April or May. The second mode of treatment is rather to be preferred to that just described, inasmuch as, by following it, the plants may be brought into bloom, with certainty, during the winter months. In autumn the bulbs should be potted, and placed in the warmest part of the room, but not far from the window. The pots may be placed on a Dutch stove, the temperature not being allowed to exceed 80° Fahr. If it goes beyond this, a tile or a brick should be placed under the pot. Here they should receive no water until the sheaths of the flower-stalks appear. These, under this mode of culture, are always developed before the leaves. The pot should now be placed in a window of the heated room, and thoroughly watered with warm water, a saucer being placed under the pot to receive the water that escapes from the pot. After this time the plants should be treated in the ordinary way, and after flowering should be watered until August whenever they are dry, liquid manure being given from time to time. From the beginning of August the supply of water should be gradually diminished, and after the

1st of September no more should be given. At the end of September the plants should be transplanted, the old soil of the ball being quite shaken out, and all the decayed roots removed without injuring the sound ones; and, after this, the same routine of culture should go on as in the year before. In addition to the foregoing, we must not overlook some species which have long been favourite plants for room-culture, but which have not been employed in the production of hybrid varieties. These are *Amaryllis formosissima*, a Mexican species, known also under the name of *Sprekelia formosissima*. In autumn, the bulbs of this should be laid (not planted) in the warmest part of the room, but not immediately on the stove. Here they should be allowed to remain until the sheaths of the flower-stem issue from the crown. Then they should be potted, placed in a window of the heated room and watered whenever they become dry. In two or three weeks, and before the leaves appear, the large, solitary, deep purplish-red blossom will open on the top of the stem. After flowering, the treatment should be similar to that of the *Amaryllises*, which, according to the second mode of culture which we have described, are kept dry after being planted until the flower-buds appear. In September the bulbs should be taken out of the pots, and the same treatment repeated as in the previous year. *Amaryllis solandræflora* var. *vittata* is a native of tropical America, and has very large funnel-shaped flowers, which are, in the ordinary form, green, but in the variety called *vittata*, are of a dull white, with two reddish longitudinal streaks. It should be treated according to the first mode of culture described. *Amaryllis* (*Nerine*) *sarniensis*, *A. (Nerine) undulata*, *A. (Vallota) purpurea*, *A. Belladonna*, and *A. blanda* are all natives of the Cape of Good Hope. When grown in the window of a room they bloom in September, and, therefore, do not properly belong to the class of winter-flowering plants; they are all handsome plants, but *A. undulata* is the only one which blooms annually. The others are often very tedious in blooming, and are, therefore, not to be recommended, notwithstanding their beauty.

Grape Hyacinths (*Botryanthus*). These pretty dwarf bulbous plants, with blue flowers in dense clusters, and better known as Grape Hyacinths, are various species of *Botryanthus*. They are natives chiefly of the vineyards and pastures of Southern Europe, and are known in gardens under the name of *Muscari*. *B. odoratus* and *B. vulgaris* both have dark blue flowers, while those of *B. pallens* are sky-blue. When the leaves are withering, the bulbs should be taken up and left to dry in a dry shady place. In the end of August or the beginning of September, they should be planted, four to six together, in 4 or 5-inch pots, and placed in a cool position sheltered from frost. They should not be watered. In the beginning of December they should be removed to a room where the temperature is kept above freezing point, or moderately warm; here they should be watered. When the flower-buds begin to show, the plants should be placed in the window of the temperate room, where they will come into bloom in January or February, according to the heat of the room. After flowering, they may be kept through the summer in a dry place, where no water should be given to them, and, without being transplanted, they may be forced again the following winter.

Clivia miniata.—This is one of the finest and most free-blooming of bulbs for flowering in February, March, and April. Its vermilion flowers, which resemble those of a small *Amaryllis*, are produced in a large umbel of from eight to fifteen blooms on the top of a stem 6 inches to 1 foot high, rising from the midst of evergreen ribbon-like leaves, arranged in two rows. The culture should be according to the first mode given for the *Amaryllis*. The other species of *Clivia* also make good room plants, although none of them are as handsome as *C. miniata*, or bloom so freely and abundantly when grown in rooms. *C. nobilis*, from South Africa, is the longest-known kind. Its flowers are of a pale red, considerably smaller than those of *C. miniata*, and appear in February and March. *C. Gardeni*, from Port Natal, is handsomer than *C. nobilis*, but not so fine as *C. miniata*; moreover, it frequently does not bloom before summer. *C. cyrtanthiflora* is a hybrid between *C. nobilis* and *C. miniata*, and blooms at the same time as *C. nobilis*.

Crocuses.—Most of the species of *Crocus* are natives of the mountains of Switzerland and the south of Europe, where they bloom soon after the snows melt in spring. The species with blue and white flowers are *C. vernus* and *C. biflorus*. The parent of the yellow-flowered kinds is *C. luteus*. Those with streaked, or variegated, flowers have sprung from *C. reticulatus* and *C. versicolor*. The treatment is the same as that for *Botryanthus*, only that as soon as the flower-buds appear, the plants may be removed into the heated room to flower. Care should be taken not to place them in the heated room before the flower-buds show themselves; otherwise these will not make their appearance at all. But when the growth has already reached this point in a cool or temperate room, the flowers will open in a few days after the plants have been removed to the heated room.

Dog's-tooth Violet (*Erythronium Dens-canis*).—This is a native of the European Alps and Siberia. The two oval radical leaves are marbled with brownish spots. The flowers are drooping, and of a rosy colour, somewhat like those of a *Cyclamen* in shape, but considerably larger. It should be planted in a mixture of equal parts of loam and peat. The bulb-like root-stocks should not be allowed to dry too much after they are taken up; they should be potted in August, and kept without water in a cool place until the middle of December; they should then be removed to the double window or the window of a temperate room, where they will come into flower in January and February.

Eucharis amazonica, **E. candida**, **E. grandiflora**.—These are all natives of tropical America, and rank amongst the handsomest of plants for winter-flowering in rooms. Their flowers are white and fragrant, and are produced in umbels on the top of a naked flower-stem, like those of a *Pancratium*. Their treatment should be according to the first mode given for the *Amaryllis*. The flowers appear at different periods in the course of the winter.

Fritillarias.—Of this genus only the Snake's-head (*F. Meleagris*), a native of Europe, and the pale-flowered kind (*F. pallidiflora*), a native of Central Asia, are to be recommended for winter flowering. The common kind (*F. imperialis*) comes too late into bloom. The original *F. Meleagris* has flowers which are chequered with brown squares, on which account the name of Chess-board Plant has been given to it; but there are varieties with light speckled and even white flowers. *F. pallidiflora* has pale yellow flowers. They should be treated like *Botryanthus*, but should be kept only in a temperate room, where they will bloom in February and March.

Ismene calathina.—This is a native of Brazil, and is allied to *Pancratium*. It bears two or three large white (sometimes yellowish) fragrant flowers on the top of a stem from 1½ to 2½ feet high. It should be treated according to the second mode of culture given for the *Amaryllises*. The flowers, however, do not appear until the leaves are almost fully grown. Water must therefore be given as soon as the latter begin to show themselves.

Iris.—The bulb-like root-stocks of the Persian Iris (*I. persica*) should be potted four or five together in 5-inch pots in loamy soil in October and placed in a cool room. After the middle of December they should be removed to the heated room. It is a very easily forced plant, and blooms from the middle of January. The flowers are variegated with pale blue on stems about 9 inches high. After flowering they are to be treated like the Hyacinths. *I. reticulata* is a native of the Caucasus. Its bulbs are covered with a reticulated coat, from which the species derives its name. In the open air it blooms at the same time as the Snowdrop, and is forced in the same way as the Crocus. The flowers are blue. When potting, eight or ten bulbs should be put into each pot. *I. Xiphium* and *I. xiphioides* are both natives of South-western Europe, and have bulb-like root-stocks and flower-stems about a foot high, narrow leaves and large flowers, which vary from deep blue to nearly white, and are variegated in various ways. The first is also known in gardens as *I. hispanica* and the other as *I. anglica*. They should be placed in the heated or cool room about a month later than *I. reticulata*. In other respects the treatment is the same. *I. susiana* is a native of the east, and one of the handsome kinds with large flowers,

which are veined and spotted with brownish-purple on a grey ground. The plants should be potted in loam well-mixed with sand, in August or September. They should not be watered, and in February the pots should be placed in a sunny part of the double window, and in a temperature of from 40° to 48° Fahr. Here they should be watered very carefully, and as little as possible. The truly handsome flowers appear in April. In other respects the treatment is the same as that of *Cyclamen persicum*.

The Spring Snow-flake (*Leucojum vernum*).—This is a native of Central Europe. Treatment the same as for *Botryanthus*. It blooms with the Snowdrop from the middle of January.

Pancratium speciosum.—This is a native of the East Indies, and is one of the handsomest and most distinct bulbs for winter-flowering in the heated room. The large white flowers are produced in umbels in November and December. It should be treated after the first mode given for the *Amaryllises*.

Puschkinia scilloides.—This comes from the Caucasus, and bears clusters of pretty bright blue flowers, like those of a *Scilla*, on stems 8 or 9 inches high. Treatment the same as that of *Botryanthus*. It is known in gardens as *Adamsia scilloides*.

The Asiatic Crowfoot (*Ranunculus asiaticus*) is a native of the East. Its pretty double-flowered varieties are well known in gardens. For forcing, the sub-species, known as the Turkish *Ranunculus*, is the best. The roots intended for forcing should have been previously laid in a dry room without any soil for at least two months, if a good result is expected. Those intended for the earliest flowering should be potted at the end of August, and the rest should follow at intervals of from seven to fourteen days. Before potting, the roots should be soaked for some hours in water, and then potted, four or five together, in 4-inch pots, in free loam. The pots should then be placed in the window of a temperate room or in the double window, when, from January forward, according to the time of potting them, they will come into flower. None of the *Ranunculi* should be forced to flower in the heated room, as they cannot bear such a high temperature.

Squills.—The two-leaved Squill (*Scilla bifolia*) is a native of the forests of Western Europe and Switzerland, with loose clusters of sky-blue flowers on stems from 3 to 5 inches high, and blooming shortly after the *Leucojum*. The Caucasian, or Crimean variety (*S. bifolia* var. *taurica*, Rgl.), which is a more robust plant, about 9 inches high, bearing numerous flowers in clusters, is still finer than the common form. *Scilla cernua* is a native of Eastern Russia and Siberia, and handsomer than the preceding kind. There are often not more than one or two flowers on each stem, but each bulb produces many stems, and the flowers are much larger and of the deepest sky-blue colour. This is also known in gardens and horticultural works as *S. sibirica*, *S. amoena*, and *S. amænula*. *S. bifolia* and *S. cernua* are to be treated in the same manner as *Muscari*. They bloom in the end of December and beginning of January. *Scilla campanulata*, *S. nutans*, and *S. patula* are all three natives of Southern Europe, and are closely allied to each other. They are known in gardens as Roman Hyacinths and *Hyacinthus non-scriptus*, and are also classed as genera under the names of *Agraphis* and *Endymion*. They have broader leaves than the two preceding species, and stems more than 9 inches high, with looser spikes, which usually contain a greater number of flowers of a blue or white colour. If the bulbs are taken up soon after flowering, kept dry, and potted in August, or the beginning of September, four or five together in 5-inch pots, they will come into flower in November. The treatment is to place them in the cool room in the beginning of October, and fourteen days afterwards to remove them to the heated room.

Tulips.—The common Tulip is a native of the East, and is the parent of the numerous garden varieties. *T. suaveolens* and *T. præcox* are natives of Southern Europe, and are the parents of the kinds used for forcing. The treatment is the same as for the Hyacinths, only we must remark that the *Duc van Thol* should be potted in September for forcing, placing single bulbs in small pots or from three to five bulbs together in 4-inch pots. In October they should be placed in the cool

room, and in November removed to the heated room, when each pot should be covered by another larger pot, inverted. They will bloom by the end of November. The hybrids from *T. præcox* and *T. gesneriana* should be potted at the same time as the Hyacinths, three bulbs together, in 4 or 5-inch pots, and placed in the cool room in December. In January they should be removed to the heated room. The common Tulip and its varieties should not be placed in the heated room before the end of February. We recommend the following kinds for forcing. (1) From November to the middle of January:—The single *Duc van Thol*, with red and yellow, pure yellow, red and white, pure white, scarlet, crimson, golden variegated, and fiery red flowers; and the *Duc de Berlin* in similar colours, but with larger flowers. (2) From January to the end of February:—Single: *Clairmond*, *Vermilion brilliant*, *Feu de Moscou*, *Duc de Paris*, *Duchesse de Parme*, *Aimable Elizabeth*, *Etendard d'Or*, *Canary*, *Bride of Haarlem*, *Commander of Malta*, *King Pépin*, *Wapen van Leyden*, *Catherine Isabella*, *Belle Sylvander*, *Laque Triomphante*, *Paragon van Grieken*. Double: *Duc van Thol*, *Rex Rubrorum*, *Couronne des Roses*, *Le Blason*, *Tournesol*, *Duke of York*. (3) From February to April:—Single: *Pottebakker*, in yellow, red, and white. Double: *Geel Rose*, *Grand Maître*, *Pourpre*, *Agréable*, *Sylvia*, *Wittenrod Bordé*.

Veltheimia viridifolia.—This is a pretty bulbous plant from the Cape of Good Hope. From amid the broadly lancet-shaped leaves rises a flower-stem from 1 to 1½ feet high, bearing on its summit a dense cluster of tubular pale rose-coloured flowers. In winter it should be placed in the double window, or in the window of a temperate room, where it comes into flower in March; and in summer it should have a half-shady position in the open air. It should be watered moderately throughout the summer.

M.

Gardeners' Wages Five Hundred Years ago.—In these days of high wages it may be interesting to note the wages of a head gardener 503 years ago. In 1372 John of Gaunt issued a warrant, which is still in existence among the archives of the Duchy of Lancaster. It is addressed to his receiver-general, and having recited the engagement of one Nichol Gardiner as "nostre gardynere"—the surname and the office being differently spelled—for "nostre manoir de la Sauvoye," it proceeds to define his duties and emoluments. Nichol, we observe, is to have all the fruits and "herbages" for his own profit, saving only what is required for the household, but is to manure and work the garden at his own cost and charges, and to provide all things needful, "busoignable," for its due cultivation. The Duke, on the other hand, stipulates to provide him with rails and fences in the railing season, "en temps de raillement," and for wages commands the receiver to pay him the sum of twopence a-day whilst he is retained as gardener, or, in the old Norman French of the period, in which the warrant is written, "deux deniers chascun jour le temps qu'il serra ensi gardynere."

Single White Hepatica.—Miss Hassard alludes to the value of the flowers of the Hepatica in bouquets, but she mentions only the pale blue and the double pink. The blue kind, known as *Angulosa*, has large flowers; so also has the single red; and those of the double blue are large, and of a deep hue of colour. Foremost amongst all of them, however, is the single white, which is a veritable gem, and is one of the prettiest of early spring flowers. I commend this amongst all others to bouquet makers, because its earliness, its colour, its size, and its beauty, make it especially valuable for button-holes.—A. D.

Boxwood as a Scraper.—Where Boxwood does well, a mass of it on each side of a door proves a capital scraper or mat in wet or snowy weather. The only time during which it cannot be used much is when it is making its growth, but at all other seasons it may be used in moderation for cleaning the feet; and, if done with any degree of care, the drawing of the sides, toes, and heels of boots over it, injures it very little, and, of course, it is cleaned after every shower of rain. Where a flower-border runs round the house, the ordinary Box edging will do, if allowed to grow larger than ordinary near the door; but, on gravel, it might be planted in the form of a figure, such as a comma, a square, or a half-moon, or any other shape desired.—CHEVALIER.

Anti-rabbit Composition for Young Trees.—There have been enquiries in your paper and others of late about the best anti-rabbit composition. Until last year, we have for a long time here used—with the best results—a mixture of lime, water, and cow-dung, made pretty strong. There should be plenty of the latter ingredient, both to make it adhere properly, and because, if lime is in excess, the mixture dries too white upon the trees, and is unsightly; whereas, if properly mixed, it dries just the right shade of greenish-grey. But last year we discovered a simpler, cleaner, and equally effective composition, which is sold for the purpose by Messrs. R. Davidson, of the Scottish Colour Works, Leith. It is very cheap (a 56 lb. cask has lasted two seasons here), and is quite inoffensive to touch or smell. Being semi-transparent, it is invisible when applied to trees. Most trees outgrow danger from rabbits; which, as a rule, will only attack young trees; but Hollies and Laburnums are never safe, and the largest specimens are liable to destruction by these little pests.—SALMONICKERS.

THE FRUIT GARDEN.

VINE EYES IN TURF.

THE season is now at hand for commencing to raise young Vines, either for pot culture or for planting out, and many gardeners have not the convenience of a propagating-house or other suitable structure for the purpose. In the spring of 1859 I was similarly situated, for I had removed two Vines of the White Nice variety, which were to be replaced by eyes from a favourite Muscat which we had. Wishing to fill up the blanks thus made as speedily as possible, I placed a slate upon the hot-water pipes of the Vinery, which were about 3 feet 6 inches from the glass, procured a fibrous sod, about 12 inches square and 2½ inches thick, and into this inserted, in a slanting position and up to the buds, nine Vine eyes, only two of which would eventually be needed. I watered the sod three or four times a day, according to the heat of the pipes, with water from which the chill had been taken; in fact, I kept it constantly saturated. Both roots and buds soon began to push, and, when the former were sufficiently advanced, I cut out two of the strongest, with a sod about 4 inches square attached to them, which was well filled with roots. Procuring another sod 10 inches square and 3 inches thick, I turned it upside down, and cutting a hole in the centre 4 inches square, I placed in it, a little deeper than before, the rooted eye with the smaller sod. As I kept it constantly moist the roots spread rapidly and the young shoots soon became strong. As the roots appeared at the sides of the sod I cut off the points with a sharp knife, which caused a quantity of side roots to push, and as soon as the sod was well filled with them I raised the slate off the pipes for a few days to harden them off before planting out. To prevent the young roots taking a downward direction, which they are generally inclined to do, I then made a hole in the border large enough to admit the slate, and then planted all together, leaving the slate to give the roots more of a lateral direction, and watering the whole to settle down the soil. The Vine not receiving the slightest check was soon at the top of the rafter. After having the centre pinched out at 4 feet from the starting point, it finished off two splendid canes, which were allowed to carry two bunches each the following season. I was so well satisfied with the results of my experiment that I have practised it ever since, both for planting out and for fruiting in pots. In the latter case I merely cut the second sod in a circular shape according to the size of the pot intended to be used. Treated in this way the young growth never receives the slightest check in re-potting, an advantage that should always be kept in view, either in raising young fruit trees or plants.

JAMES SMITH.

Waterdale, St Helens.

APPLICATION OF SULPHUR TO VINES.

I HAVE letters on this subject from several persons interested in Grape growing, and as it is one of considerable importance, I may state that the period when red spider is most likely to appear and increase on Vines is when the fruit has commenced to colour. Syringing is then suspended, to admit of this being accomplished perfectly. If red spider has gained a footing before this, it is sure to make more rapid progress afterwards, when no obstruction is offered; so that it frequently happens that by the time, or sometimes before, the fruit is ripe, the whole is overrun by this pest. The question which thus arises is whether or not the sulphur necessary to annihilate the spider would injure the fruit, but I am of opinion, if it be carefully used, that the spider may thus be disposed of without blemishing the fruit. Some years ago, I remember a Muscat-house which was overrun with red spider when the crop was all but ripe. The flow-pipes were painted with sulphur, and the fire lighted in the evening, when the house was closed and cool, until the temperature reached 90°. The fumes at this stage were very strong. The fire was then withdrawn, and the house allowed to cool down again. The operation was repeated the following evening to the same extent; next day the spiders were all dead. The bunches were closely examined afterwards, and the only damage that a few of the berries had sustained was a slight spot here and there, similar to that which sometimes appears on highly-ripened Muscats, and is known as the "robin egg spot." The flavour and keeping qualities were in no way diminished, while the wood was greatly benefited in having no spider to retard its ripening. The fumes of the sulphur were stronger in this instance than I had ever before known, and the spider was as plentiful as it is in most cases. I have seen other instances where the spider was not so bad nor the remedy so vigorously applied, and the result was the same. Muscats are as tender in the skin as any other kind, so that I consider red spider may be killed on all Vines and at all times without the slightest injury being done to the fruit.

J. MUIR.

RUST ON GRAPES.

YOUR correspondent, "J. M.," is right, so far as he goes, in his observations respecting rust on Grapes, and his testimony will be endorsed by others who have given some attention to this subject; but the real question is, What is rust upon Grapes, and how does it affect the fruit? Your correspondent has answered the last part of this question, "it only affects the appearance of the fruit;" in fact, it is hardly skin deep; for, if anyone examines a berry, affected by rust, through a strong magnifying glass, he will see at once that the beautiful smooth skin of the berry has been decomposed by condensed moisture when the berry was in a young and tender state. Anyone may satisfy himself upon this point; although it may not be observed upon the green berry, it is nevertheless there, and expands with the growth of the fruit; thus it follows as a natural consequence that tender and thin-skinned Grapes will be most easily affected by rust. If my inference be right, I believe that the system of steaming night and morning that many pursue when their Grapes are in flower, in cold and sunless weather, is detrimental to the berries and young fruit. This practice, when Grapes are in blossom, is unnatural, and the wonder is, that so few evil consequences arise from it.

J. T.

Opening up the Hearts of Standard Fruit Trees.—In many gardens one sees plantations of fine young Apple trees mop-headed, and the branches growing hither and thither, twisted and contorted—evils caused by summer pinching and bad pruning. Our practice is to leave all the growth on our trees, which are chiefly pyramids, till August and September; all shoots are then shortened to three or four buds with the exception of the leading shoots, which are left till after all the leaves are off; they are then shortened to the length wanted, a matter depending entirely on the size of the tree. If the trees are inclined to grow upwards too much we drive in six short stakes around the base, run a strand of wire round these, and with tar-cord tie the branches down to the wire and stakes; in this way the tree is opened up; light and air are let in about the branches, and, in short, a uniform thrifty-looking tree is the result of a little trouble in tying down a few of the main branches. Care must always be taken in shortening these branches not to prune to an inside bud; this may appear a slight matter at first sight, but it is of the utmost importance if you want a uniformly handsome tree to prune to an outside bud. In this way the tree gets outwardly developed, and relieves itself of overcrowding on the inside. It is to be hoped, now that we are ceasing to turn our kitchen-garden borders into ribbons, more attention will be paid to our hardy fruits and finer legumes than has hitherto been the case.—CHEVALIER.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Peaches Setting.—I do not think that Peaches ever set better here than they have done this year in our first and second Peach-houses, and we certainly never had more dark or more unfavourable weather when the trees were in flower. We, however, fired up well during the day, dropped the temperature at night, dashed the trees and flowers with a fine syringe several times a week, and almost every flower has set.—J. S. W.

Planting Alpine Strawberries.—Runners planted now, or as soon as the weather breaks, in rows 1 foot apart, and 8 inches asunder in the rows, in land well manured some time previously, will come in usefully in August and the two following months. When the plants are well established, mulch heavily with manure. Cut off all flowers that appear before the end of July. Seeds sown now in heat, pricked off when large enough to handle, and planted out in May, will bear in the autumn.—E. HOBDAK, Ramsay Abbey.

Gros Colman Grape.—Mr. Greenfield, of the Priory Gardens, Warwick, writing in the "Gardener" for February, says, with regard to this fine late Grape, "Allow me to endorse Mr. Thomson's statement respecting this fine late Grape. I think the same terms apply to the Gros Colman as to the Raisin de Calabrie. When it is well grown it is a splendid Grape. It is a Grape that requires to be started early (say February), and allowed plenty of time to finish. It swells immense berries, like Plums; colour and flavour unsurpassed as a late black Grape."

Waltham Cross Grape Vine.—When sent out I procured two plants of this 8 inches in height; one was planted out in the Cucumber-house at one end of the bed, its roots being confined to a space 3 feet square and 8 inches deep. Here it produced and ripened a fine cane, and by the third week in June following it ripened off in perfection eleven bunches of Grapes, each averaging in weight 2½ pounds, and of the finest golden-amber colour. The other Vine was planted out in a Vinery in the spring of 1874, and was allowed to ripen two bunches, each of which was 2 pounds in weight. They were ripe the first week in August and kept good on the Vines until the first week in December.—RICHARD NISBET, Aswarby Park.

Pear Naquette.—This valuable early Pear, Naquette, is sometimes confounded with the Autumn Bergamotte, but it is quite distinct, and ripens much earlier. The trees of both these varieties attain a large size, and the fruits are somewhat similar. The fruit of the Naquette is larger, rounder, and greener than those of the Bergamotte, and ripens quite two months earlier. It is also more juicy than the Bergamotte, but the flavour is not quite so rich. I have large trees 20 feet high of both sorts, and I think I may venture to say that I know both well. This Pear is not much known in this country, but as an exquisite early variety it deserves extensive cultivation, as much for its flavour as for its heavy cropping qualities.—JOHN SCOTT, in "Gardeners' Magazine."

FERTILISATION OF FLOWERS.

WE have recently heard much from scientific men and horticulturists respecting the part which insects take in the work of intercrossing our wild flowers. In modern times man himself has commenced improving cultivated flowers, and the result is to be seen in the hundreds of beautiful varieties of Pansies, Pelargoniums, Asters, Chrysanthemums, Cyclamens, and other favourites that now grace our gardens. We know of no source of amusement more interesting than the experimental intercrossing of two varieties of any popular flower when both are in bloom. A pair of fine-pointed scissors to remove the anthers or pollen-cases from the seed-bearing plant, and a camel's-hair brush to transfer the pollen from the anthers of one to the stigma of the other, are all the implements required for the operation. The pollen is the yellow powder-like substance found in most flowers, in some of which—the Lily for example—it is very conspicuous, and after it is applied to the stigma a curious process takes place. Each pollen grain throws out a tube, as shown in our illustration, and this forces its way down the cellular tissue of the style into the ovary below where fertilisation takes place. These tubes serve the purpose of transmitting the fluid contents from the pollen grain to the embryo ovules in the young seed-vessel. This curious growth of the pollen grains takes place occasionally with great rapidity; and, in some plants—the common Crocus for example

Pollen Grains magnified.

—the tubes have to force their way for several inches down through the tissues of the style. Our knowledge of the process of fertilisation, as carried on in different plants, enables us to obtain new varieties, and these, by blending the characteristics of both parents, are in many cases far more beautiful in colour and form than either of the sources from which they have sprung.

B.

Value of Land in Ireland.—It is stated, in "Thom's Almanac" for the present year, that the average price of land sold in the five years ending 1867 was 17½ years' purchase; in 1868 it rose to 18½ years; in 1869 it fell to 17½, and in 1870 to 16½ years. In 1871 (the first year of the Land Act of 1870 being in operation) the price rose to 18½ years; in 1872 to 19 years, and in 1873 to 20 years' purchase. The annual valuation of lands, houses, and tenements, in Ireland, is upwards of 13 millions. If we deduct three millions for the valuation of houses and tenements, it will leave ten millions as the value of the land. We may probably add one-fourth to this valuation, which would make the rental 12½ millions. The increase between 1870 and 1873 was three and a half years' purchase, which represents a capital of £43,750,000 added to the value of the estates of the land-class by giving greater security to the tenants.—"Irish Farmers' Gazette."

THE INDOOR GARDEN.

THE NEAPOLITAN VIOLET.

THE Neapolitan has had many rivals among Violets; yet it still maintains its position as the best. The individual flowers are the handsomest of all the double varieties. The colour is delicate, and the scent of a peculiar sweetness; its stiff shining green leaves, with the flowers bristling just above them, give it a much more handsome appearance, as a plant, than any of the other varieties. Like most spring flowers, it is particularly well adapted for forcing in winter; no plant of the same size yields bloom in such profusion, or that lasts longer. The same plants will go on blooming, more or less, from the 1st of October till April. This Violet is hardy on the south-west coast of England, and in inland counties blooms in the open air, during mild weather, throughout the winter. In the north it can scarcely be called hardy, and, except in sheltered nooks in the south, the flowers suffer from frost. To have them in perfection, and keep the plant in full vigour of health, so as to obtain a continuous crop of flowers, it is necessary to protect it with glass. This is what is called Violet forcing, though in reality the plant is impatient of heat, except in a very mild form at the root—and even then heat is sometimes more productive of leaves than flowers. Success in forcing Neapolitan Violets depends more particularly on the preparation the plant has received during the previous summer, than on the immediate means used to bring out the flowers; that is, the flowers must first be grown before they can be made to open. This month is a good time to begin preparing Violets for the following winter's flowering. Get two or three lights of a cold pit or frame in readiness by putting in 4 inches of soil, consisting of sandy loam and leaf mould sifted fine. From the plants which are under glass and in good health, free from red spider on the leaves, and with their foliage undamaged in any way, proceed to take off side shoots for young plants. Select the short stout shoots or runners with a bunch of young white roots attached, which they are sure to have at this season; avoid long wiry horizontal runners, for they are of no use; avoid, also, old crowns which have been flowering all the winter, as these are not worth having in comparison with the young side shoots. Insert them in the frame in rows 3 inches apart each way, and water them in with a watering-pot having a very fine rose. Draw the lights over them, leaving a little air on, except during frost; shade from bright sun for a few days, and, by the middle of April there will be a number of sturdy plants to be transplanted to their summer quarters; or the old plants, after flowering, at the end of March may be lifted and pulled to pieces, and a sufficient quantity of the young stiff side-shoots, which have already made a bunch of roots, selected from amongst them. These can be at once planted in the ground chosen for growing them in throughout the summer, but the first is the preferable plan. By adopting it, the young plants receive no check when planted out during the moist weather of April, when they should be in the most active growth; they also are better able to get a good hold of the soil before the hot dry weather of summer ensues. The choice of a good position in which to grow these Violets is a most material point in their culture; and a moist border, under a wall or hedge facing the west, will be found to suit them admirably. The plant delights in a somewhat stiff soil, with plenty of moisture to feed upon during the hot days of summer; if planted in a dry soil facing the sun, it invariably becomes a prey to red spider, the foliage gets injured and exhausted, and a crop of flowers is out of the question. The same ground may be occupied year after year by Violets, if the ground be dug in winter, and a light dressing of thoroughly rotten manure (or leaf mould, if the soil be heavy) be worked in. About the middle of April, the prepared plants should be removed and planted in their summer quarters, care being taken to preserve the balls entire. Plant them with a trowel a foot apart each way, making, with the foot, the ground firm about the plants and between the rows, and finally watering them. They will want no more water for weeks, or until, under the influence of dry weather, the soil may show signs of requiring it, when the whole should be watered thoroughly. The summer

culture, besides watering, only consists in keeping the ground clear of weeds, and cutting away all the wiry horizontal runners as they appear; they will not be very troublesome until August, and the most effectual means of getting rid of them is by the use of Grape-scissors, the fine point of which reaches the base of the runner amongst the thick bunch of leaves, without the danger of cutting the leaf-stalks instead. By the first week in October the plants will be coming into bloom, and then is the time to have them removed to pits for the winter. In the south, all that is necessary is to fill the pits with any good friable soil to within a foot of the glass, sloping it from back to front; in this plant the Violets with their roots lifted with balls of soil entire, and place them as closely together as they will pack. The balls are, as a rule, so large in proportion to the tops that the plants above ground will be wide enough apart. In the northern parts of the country it will be necessary to place a body of leaves, or a mixture of leaves and litter, under the soil, to produce a gentle and continuous bottom-heat during the early part of winter, in order to keep the plants gently growing, and to exclude sharp frost. The plants must be kept dry, removing the sashes in fine weather, and not allowing a drop of rain to fall on the plants, as damp is their great enemy in winter, especially in pits, where bottom-heat must be used. Damp is not so troublesome in cold pits in the south, provided the plants be kept from rain. They must be frequently looked over, and all damp and decayed leaves removed. The surface of the soil may be sprinkled with dry sand if damp be causing damage. Frost must be excluded by covering up the pit with a thick coat of dry litter, and lining the outside with the same material. Sometimes it will be necessary to keep the pit closely covered up for days or even weeks during severe weather; the flowers open but slowly at those periods, and will be found to be without scent, which will, however, return with a few hours' exposure to sunshine and fresh air. Red spider is the Violet's greatest enemy; it is hopeless to contend against it by syringing or sulphuring the plants; when spider attacks them in a determined manner, it is a sure sign that the plants are growing in an unfavourable soil or position, or are too dry at the roots, and a radical change in the management must be effected; no half-measures will be satisfactory, but spider will not be troublesome even during the heat of summer if the plants are allowed abundance of nourishment at the root.

W. D. C.

LATE-FLOWERING LILIUM AURATUM.

THIS Lily succeeds well enough out-of-doors in some parts of England, but here, in Yorkshire, at a considerable altitude, it does not, although it is hardy, produce its flowers in perfection in the open air. To flower it well it must be grown in a greenhouse; and, however cool this structure may be, it will come into flower long before it is wanted. To keep it back, about three years ago, I kept the bulbs, after potting them in a cold pit during winter and spring, in a north aspect, and afterwards, during the summer, the plants were set behind a high north wall out-of-doors, in as cool a situation, in fact, as we could find for them. Notwithstanding this treatment, however, they persisted in opening their buds about the end of July, and the flowers were inferior in size, colour, and fragrance—in consequence, no doubt, of the plants having been grown entirely in the shade all the season. The following year I tried the experiment of planting the bulbs in the herbaceous border just after they were started in the pots, but with no better success; for, though we had a few later flowers, most of them had to be cut and sent to London with the other flowers during the season, as it was not wished that they should "blush unseen." To continue the experiment, the roots were left in the ground all the winter, and, whether owing to the later ripening of bulbs or the coolness of the soil I cannot say, but the stems the next season (1874) did not appear above ground till May and June, and were much weaker in appearance than in the previous year. But they were late enough this time, the first of the flowers not opening till near the end of October; and, frost coming at that time, we cut the spikes with what expanded flowers they had, and stuck them in the vases in the house, where the remaining buds opened freely and lasted for more than a fortnight. The bulbs were taken up in November last and potted in good but dry soil, and kept in the fruit room till lately without the bulbs moving perceptibly; but, as the temperature rose the other day, we moved them into the ice-house, where the thermometer stands generally about 36°.

The soil about the roots being comparatively dry, and the pots not being in actual contact with the ice, I hope to keep them at rest till May or June, when they will be taken out and grown on freely under glass, so as to have them in at the desired time.—"Field."

PROPAGATING DOUBLE PRIMROSES.

IN answer to your correspondent who inquires about double white Primulas, allow me to say that the old plants may be broken up, and the cuttings struck in a brisk and rather moist heat in April or May, each cutting being placed separately in a thumb, or small 60-sized pot, with the soil pressed firmly round the crown. When fairly rooted, they should be shifted into a 4-inch pot, and again placed in a rather moist heat until they begin to take to the fresh soil, when they should be transferred to a more airy house, and placed upon a shelf, as near to the glass as possible, without actually touching it. As they fill their pots with roots, they may afterwards be potted on. Care must be taken not to overwater the plants after re-potting, for if the soil gets too wet before the roots have begun to work in it, they will not take to it kindly; but, when once established, they must not be allowed to get dry. It is well to shade them slightly from the strongest sunshine in summer, but be careful to remove the shading immediately the sun-heat diminishes, or that substantial growth so essential to all soft-wooded plants for winter forcing will be lost. The soil I have found to suit them best is a compost of three parts of good turfy loam, one of peat, and two of leaf mould, with a liberal addition of silver-sand, and also a little well-rotted dung. A great mistake is often made in potting these Primulas by leaving a portion of the stem (below the collar of the plant) above the soil; for this renders them very liable to damp off. They should always be potted up to the crown, but not so deep as to bury it; so that the bottom leaves just rest upon the surface of the soil. A temperature of 55° to 60° should be maintained throughout. There are several varieties of double Primulas in cultivation, but the best white I know is *delicata*, the flowers being large, full, and beautifully fimbriated.

BEN. MATTHEWS.

The Nurseries, Ponder's End.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Pots that Exclude Worms.—I chanced to see some pots the other day which had come with some plants in them from the south of Spain. They have no hole for drainage at the bottom at all, but they have one at about a quarter of an inch from it in the side. The gardener says that where one worm finds its way into one of these pots, ten would do so with those we ordinarily use.—W. EW BANK, *St. John's Vicarage, Ryde.*

Ready Way of Propagating *Cissus discolor*.—This is one of the most desirable of plants for draping baskets in the stove. Every bit of last year's wood cut now into pieces two joints long, will root in sandy peat, with a sprinkling of sand on the top; place half a dozen cuttings round the side of a large 60-sized pot, and plunge them in a bottom-heat of 75° or 80°.—E. HOB DAY, *Ramsey Abbey.*

Planting out Large Camellias.—Your correspondent (see p. 168) cannot do better than plant out his large Camellias at once. Let him cut away all their strong roots; even if they are as thick as one's arm he need not hesitate to remove them. About ten years ago, I removed some fifty plants of Camellias of thirty years' standing, pruned all their roots to within 15 inches of the stem, trenched the border, adding some fresh turfy soil to it, and not one of them failed to do well.—HENRY GADD, *Wollaton.*

Stewart's Double Chinese Primrose (*Primula sinensis Stewartii*).—This is an excellent strain of double pink Chinese Primula. It is remarkably robust in habit, even as much so as any of the common single seedlings; and its flowers, which are produced in profusion, are very large and perfectly double, while their light crimson colour attracts every one who sees them. Some plants of this variety, received from Messrs. Stewart & Sons, of Dundee, have this winter been very brilliant.—W. DICK, *Canford.*

Camellia *valtevedra*.—Allow me to inform all lovers of Camellias that, if they have not this variety, they should get it at once. It is strong in constitution, good in habit, a profuse bloomer, and, as regards form, the blooms are perfect models, being full of petals to the centre, in which they stand up, while the side petals lie down and are imbricated in the most regular manner. In colour they are the softest and brightest rose imaginable, and occasionally they have a dash of white at the tip.—N. H. P.

Hardy Plants under Glass.—Mr. Ewbank (see p. 175) and "D." (see p. 115) enquire for good hardy plants to grow under glass. For spring decoration of their greenhouses they will find few better plants than the common large-leaved Saxifrages (of the *Megasia* section)—especially *S. ligulata*. The flowers last a long time on the plant, and if cut they are excellent as cut flowers in glasses, or for ladies' hair. Many other Saxifrages do equally well, and probably *S. Cotyledon* never flowers so well out-of-doors as under glass.—H. N. ELLACOMBE, *Bitton Vicarage.*

How to Treat *Gleichenias*.—Would you give me some hints as to the cultural requirements of the South Australian Ferns *Gleichenia*, more especially *Speluncea*?—JOHN MARTEN. [*Gleichenias* may be grown in a flat pan, as they are surface-rooting Ferns, and they do best in a fresh open compost of fibrous peat, turfy loam, and sand. The peat and loam should be broken into lumps the size of pigeon's eggs with the fingers, and the pans used should be perfectly clean, and well-drained. *G. Speluncea* grows well in a moderately humid plant-stove or warm greenhouse, and requires careful and regular watering at the root when growing, and it should never be allowed to become root dry. Use tepid water, and carefully shade the plants from bright sunshine.—B.]

THE FLOWER GARDEN.

DELL'S ORNAMENTAL CRIMSON BEET.

BESIDES being useful for culinary purposes, this Beet is highly ornamental. It is, in my opinion, the best in flavour, colour, and form; and for garden embellishment surpasses every other kind of dark-foliaged plant. *Iresine Lindenii* and *Perilla nankinensis* are the nearest approach to the same shade, but not of such a bright conspicuous hue. It may be used in any arrangement in either bed or border. In ribbon borders I like to see it placed as a central line between yellow *Calceolarias* and the white *Centaurea ragusina*. Light-colour-foliaged *Geraniums* serve to give the same effect. Its cultivation is very simple; sometimes the seed is sown in the flower-bed in the form required, but this system is not convenient, as the seed must either be sown early, so that the young plants may be up and growing when the other plants are put out or sown at this time, when they are too late to be of any service in the forepart of the season. The best mode I have seen adopted, and the one which I prefer, is to sow the seed in the kitchen-garden in the Beet-beds about the beginning of April, and use the thinnings for transplanting in the flower-garden at bedding-out time, when they are a good size for immediate effect, and, if watered when planted, they do not suffer in the least from their change of position. These roots may be lifted and stored with the others for kitchen requirements during the winter. I have seen prize Beetroot selected from the flower-garden. Care should be taken that this Beet is obtained "true," or disappointment may follow.

J. MUIR.

CISSUS DAVIDIANA.

THIS is a native of China, whence its seeds were sent to the Paris Museum, by a missionary named David. It bears a violet-coloured

Cissus Davidiana.

non-edible fruit, is extremely hardy, and grows so vigorously as to spread over a large area in the course of a single year. It may be increased by means of cuttings, either taken when green in summer, or when ripe, and placed under glass in winter. Q.

CALCEOLARIA CULTURE AND THE DISEASE.

THE *Calceolaria* disease has only troubled me once, and that was in the wet season of 1872, when we had about double the usual rainfall, viz., 60 inches. But, though I thought the wet had something to do with it, I especially blamed the treacherousness of the plants received, and I cannot get rid of the impression that the

disease—which has been so destructive lately in many places as to lead some to think we shall lose the *Calceolaria* altogether—may be, to a great extent, prevented by special treatment and careful planting. In the case above referred to, I am pretty sure that the disease was induced by careless planting. We were busy bedding out in different parts of the grounds about the end of May. One man was planting the back lines of a long ribbon border, and during my absence he had lifted about 200 *Calceolaria* plants (*aurea floribunda*) from the nursery bed without being sufficiently careful to secure good balls to the roots; and, to make things worse, he had laid them all down on the surface of the soil in the row before beginning to plant, thus exposing them to a bright sun, which no doubt injured the roots seriously. I was so vexed when I discovered what had been done, and felt so doubtful about the plants growing well, that I would have re-planted that part of the row with fresh plants if they could have been spared. The remaining portion of the row—about half—was, however, planted more carefully, the whole watered when finished, and the ground frequently stirred afterwards to prevent evaporation. As I expected, those carelessly planted hung fire for a time, and never made such plants as the others. About the end of July they began "going off" with the disease in the usual way, and by the end of August not a plant was left. With the exception, however, of a few plants here and there, but not sufficient to break the line of yellow, the disease was arrested at the very point where the careless planter was overtaken. It was a striking lesson, which showed how much disappointment may be caused by the carelessness of one individual in a single instance. Comment is unnecessary; but I have reason for thinking that the row of *Calceolarias* I have referred to, or rather its absence, was a source of disquiet to the planter for the rest of the season. In the flower garden proper there was no disease worth mentioning. We have not had the disease since. Last season (1874) it committed sad ravages, especially in the London parks; with us not a single plant was affected—at least, none were observed—though the rainfall from the 1st of May till the end of July was under 3 inches, and the beds were well watered only three or four times, our water supply being early reduced; yet so luxuriant was the growth that the plants had to be shorn off the walks and bed edges more than once. And now as to treatment. In the first place, I may say that our stock has not been changed for twelve years to my knowledge. Our flower-garden beds, which are shallow (about 1 foot deep), are never manured with any other manure than decayed stable litter, of which a good quantity is given annually, and the staple is a tolerably heavy loam. We propagate about the first week in November, selecting the young succulent shoots without flower-buds, which the *Calceolaria* always furnishes abundantly late in autumn. These are made and dibbled thickly in a bed of sand and soil in a cold frame, where they remain all the winter. Sometimes they are frozen hard in frosty weather, and when this is the case the straw and mats are never removed till the thaw comes. Such plants are perfectly safe in the dark while frozen, but they would damp off if soft. When we have such frosts, therefore, as we have had lately, I contrive to get them frozen early, and have them covered up. When the thaw comes they are thawed with water just above the freezing point, and the lights taken off altogether any fine day. At the end of March or beginning of April a bed of light rich soil, 6 inches deep, is prepared out-of-doors, the *Calceolarias* are lifted out of the frame in flakes, as they all strip in a mass, and, while one man singles them out rapidly, another plants them with his hand, about 8 inches apart, picks the flower-buds off, and waters them as he goes on. We often have frost after they are planted out; but, being hardy, they resist a few degrees without protection, and, when needful, we throw a little straw over them at night. From the time they are pricked out in this way till bedding-out time, they do not grow much, but they make unusually stocky little heads and healthy foliage, and quite a host of roots; and it is the getting away of these roots, with large balls attached, to the flower beds, that I reckon upon to give them a start and carry the plants through successfully. The balls are sometimes so large, that a half-worn spade is necessarily used in planting. No reduction of the balls is allowed on any pretext, and, as planting proceeds, another man follows up with a thick mulching of Mushroom dung or old hotbed manure, putting it on tidily close up to the necks of the plants, and not missing an inch of ground anywhere. It is of no use mulching by halves. When all is finished, the beds are deluged with water from a rose till the bed is soaked through and through; after this their progress is rapid, and if the soil is examined under the mulching after a month of dry weather, it will always be found sweet and moist, and the *Calceolaria* roots close to the surface. When *Calceolarias* will not succeed under this treatment, it is quite time to discard them; but I do not think it could fail anywhere. Much, very much, however, depends on

planting. All may be ruined at this stage; and it is worth while to superintend the planting personally. I have seen planting going on by unskilled hands in parks and other places where large quantities of plants have had to be put out in a hurried and careless manner that might well shock any gardener accustomed to see the work done after a proper method. There is less chance of plants turned out of pots suffering by careless planting than such things as Calceolarias, Verbenas, Lobelias, &c., of which large quantities are now forwarded in beds and planted out with balls. A careless planter, when he finds he has not made the hole deep enough, generally brings the plant down to the desired level by giving the ball a squeeze, which effectually destroys it, and wrenches the roots as well. It is remarkably seldom that we get a new hand who does not require watching at such an operation—even upon Cabbages. First of all, make the hole of ample size, set the ball of soil with the plant down steadily, and then simply fold the soil in about it, and level up. Squeezing and pressing the soil afterwards about the plant are worse than useless; the watering and rain will settle all properly, and there is no danger of the plant blowing away. It is not a tree that is being planted, but a plant of soft tissues, with tender roots, that break with the least tension. To sum all up as regards the Calceolaria:—Get the plants up hardily, lift with good balls, plant carefully, water once or twice thoroughly, and mulch thickly. CHEF.

Evening Primroses in Utah.—With the disappearance of late spring frosts, which frequently continue to the latter part of April, and occasionally as late as early May, the intense heat of the lengthening days, rarely obscured by clouds, or tempered by showers, brings forward a rapid development of vegetation. By the 1st of May orchards have mostly dropped their blossoms; the fruit of the Apricot and Almond are developing, and Strawberries beginning to ripen, giving to fields and gardens a summer aspect. In the open country an analogous feature is brought to view in the native vegetation. We then note the appearance of several species of *Oenothera*, conspicuous among which is a large yellow-flowered one, which, being undescribed, I take (says Dr. Parry in the "American Naturalist") pleasure in dedicating to my friend, Mr. Johnson, as *Oenothera Johnsonii*. Mr. Johnson, who has had this plant for many years in his garden, called my attention to the regularity and suddenness of its opening, from fifteen to twenty minutes after sunset. This opening process, as frequently observed by both of us, is accomplished by a shrinking downward of the valvular calyx, the accumulated tension at a certain point suddenly releasing the segments from below upwards, which, becoming reflexed, allows the closely-confined convolute corolla to unfold visibly, its petals expanding in about thirty seconds, to a horizontal position. Quite constantly, just at this time, a small bee, apparently on the watch, darts in and loads itself with the stringy, adhesive pollen, to be carried, probably, to another flower. Generally, soon after, another bee on the same quest lands on the same flower, and finding the pollen gone, travels quickly over the stigmatic arms and soon flies away. This process, frequently repeated, ensures cross-fertilisation. Other *Oenotheræ* include a large white-flowered variety of the polymorphous *O. albicaulis*; as a rarity we also meet with a very neat *O. primi veris*, Gray.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Tom Thumb Ageratum from Seed.—This very desirable bedding plant does not come true from seed. Many plants, raised here last year from seed, selected and saved by myself, were quite out of character, both as regards habit and size of flowers; it is, however, easily propagated from cuttings.—E. HOBDAY, *Ramsey Abbey*.

Acacia lophantha for the Flower Garden.—This is invaluable for dotting through large beds of Pelargoniums or Verbenas. Its graceful habit of growth and Fern-like foliage effectually relieve the glare (much too obtrusive in the present style of flower gardening) that belongs to such plants. It is best raised from seed, which, if sown now in strong heat, will make large plants for this season's bedding.—W. WILDSMITH, *Heckfield Gardens*.

A New Way with Bedding Geraniums.—Where these have been wintered in boxes, instead of potting them off, as is usually done, a good plan is to take a little tough sod and to wrap around the roots of each plant, and tie; plant out on a slight hotbed of leaves, in a pit or frame. Thus treated, they grow rapidly, and can be removed to their summer quarters without the least check, the balls of earth having been filled with roots.—W. O., *Fota*.

Double Yellow Primroses from Seed.—We have at last succeeded in raising a semi-double yellow Primrose (*P. acaulis*), which is destined to become the parent of many varieties. I have no doubt that it will seed, and that its seeds will produce double varieties. The double varieties already in cultivation do not seed, or do so very rarely. I always sow *Primula* seed as soon as it is ripe, and find that every good seed vegetates. Can anyone tell me what has become of the old double white Cowslip figured by Miller?—WM. ELLIOTT.

Variegated Ivies for Root-work.—These form excellent plants with which to cover old stumps of trees or root-work, as they enjoy the partial shade of taller plants in summer, and come out with striking effect in winter. The roots being confined to a small space keeps the variegation much more perfect than it is in the case of plants that have an unrestricted feeding ground. In fact, of all the forms of variegation with which I am acquainted, that of the Ivy is the least persistent, if the roots are not restricted.—J. GROOM.

TREES AND SHRUBS.

NOTES ON BIRCHES.

The genus *Betula*, or Birch tribe, comprises a large number of species, all of which, except one, are natives of the northern hemisphere; the exception is the *Betula antarctica*, an evergreen shrub indigenous to Tierra del Fuego. The Birch is capable of supporting a much greater degree of cold than any other tree. In the Old World its northern limit is 71° upon the west, and 63° upon the east coast; in America its northern limit is 64° upon the west, and 58° upon the east. In Germany, the highest elevation at which it is found is 5,200 feet above the level of the sea; in Sweden at 3,900 feet; and in Lapland at 1,722 feet. It is worthy of remark that this tree decreases in size, not only as it advances towards the north, but also as it proceeds southwards beyond the limits of its native region. It attains its highest perfection and greatest height in Germany and Southern Sweden. The Birch is not particular in its choice of soil or situation, and will grow almost equally well in sandy, rocky, dry, or damp soil. A rich damp loam, however, seems to meet its requirements best. The commonest and most useful species of this genus are *Betula alba*, or White Birch; *B. pendula*, or Weeping Birch; *B. nigra*, or Black Birch; *B. lenta*, or Cherry Birch; *B. nana*, or Marsh Birch; *B. pumila*, or Dwarf Birch; *B. utilis*, or Nepaulese Birch; and *B. papyracea*, or Paper Birch.

The Common Birch (*Betula alba*) is met with in all the countries of Europe; and in the north of this Continent, as well as in Northern Asia and America, it forms extensive forests. In Sweden, Norway, and Lapland, it springs up in places where Fir, Pine, and Beech forests have been destroyed by fire. The size and appearance of the Birch vary considerably, according to the nature of the locality in which it grows. Upon lofty mountains it becomes comparatively small and shrub-like, thriving best upon slopes and plains. Its usual height is from 40 to 50 feet, but it frequently attains 70 feet. The bark of young trees is of a reddish-brown hue, but, with increasing age, it whitens until it assumes a beautiful silvery colour; the larger branches also become white, but the small twigs always retain their original hue. The Birch throws off the outer layers of its bark annually, and thus it generally presents a smooth and shiny appearance. Upon very old trees, however, the bark is sometimes burst and rent in all directions. The branches are slender, and at their extremities divided into numerous small twigs and rods. The leaves are ovate, sharp-pointed, and doubly serrated; they are bright green in colour, and when young emit a strong balsamic odour. The leaves droop downwards, and give a peculiar appearance to the tree, by which it can readily be distinguished from its forest companions. The flowers form catkins depending from the branches upon slender peduncles; the male catkins appear in autumn, but remain undeveloped throughout winter, and open only in spring. They bear upon each of the scales of which they are composed three quadripartite florets with four stamens. The female blossoms appear in spring; they bear upon each scale two naked germs, each of which has two thread-like styles. The seeds are ovate, and provided with two membranous wings. The ripe seeds fall in autumn, and are eagerly sought after by siskins. The timber of the Birch is white, close-grained, tough, light, and pliant. It makes excellent fire-wood, and yields superior charcoal for smelting purposes. The *sabots*, or coarse shoes worn by the peasantry in some parts of France, are made from the wood of the Birch; in Germany, spokes, ladder-beams, axe handles, and cattle-yokes are made from it; and in Great Britain it is used for turnery, hoops, and fish-barrels. Almost every part of the tree is utilised. Brooms and switches are made from the small twigs and rods. The young buds distilled in water yield a useful oil, which in taste and smell resembles balsam of copaiba. In Sweden and Norway the leaves are gathered green, and given to sheep and goats in place of fodder. Prepared with alum, they yield an excellent dye, which imparts a beautiful permanent yellow colour to linen and woollen materials. The outer bark of the tree is very tough, and almost imputrescible, and contains valuable balsamic and antiseptic qualities. In Sweden, Norway, and Finland the

bark is used instead of slates for roofing houses. Along the Volga and in some parts of North America canoes are constructed from the bark, and fishermen make their shoes of it. In Siberia and Lapland it is employed in the manufacture of boxes, baskets, hats, ropes, and drinking-vessels. In Russia, a bright reddish-brown oil is distilled from the bark of old trees; it is used in the preparation of Russian leather, to which it imparts a peculiar odour. In Poland the inner bark is highly esteemed by tanners. In America and Germany,

snuff-boxes are often made from the bark. When holes are bored in the trunk or branches in spring, before the leaves begin to expand, the sap readily flows out. This liquid is clear as water, and has a pleasant sweet, though somewhat acid, taste. Some trees yield a large quantity of sap, and as much as 10 lbs. of it may be obtained at once, especially if a bright sunny day follows upon a cold night. The sap contains a large amount of saccharine matter, and, when fresh, forms an agreeable beverage. In a fermented state it is known as Birch wine. In domestic medicine, certain preparations from the bark, leaves, and sap of the Birch are considered valuable remedies for ulcers, dropsy, intermittent fever, scurvy, and other diseases. The species of the Birch described above is extensively cultivated on account of its great value. It is propagated by seeds, layers, suckers, and cuttings. The seeds do not retain the power of germinating for more than one season. They should be sown in calm weather, upon moist soil, loosely dug, and covered with Moss. Sandy wastes

may be reclaimed by being planted with Birches; but, at the time of planting, it should always be remembered that such principal masses or trees as are to remain permanently must be arranged first, and their future size and character taken into consideration, so that the effect hereafter may not be left to chance.

The Weeping Birch (*Betula pendula*) is a very handsome tree; by many botanists it is regarded only as a mere variety of the common Birch. It is extensively planted as an orna-

mental tree in parks and pleasure-grounds, and thrives best in a damp soil. This tree is very common in the north of Sweden, where it forms a pleasing object in the landscape.

The Black Birch (*Betula nigra*) is a handsome well-branched tree, from 80 to 90 feet in height; it differs from the common Birch chiefly by its black bark. The leaves are lozenge-shaped, sharp-pointed, and doubly serrated; the petioles are long and hairy. This tree is a native of North America, from which it was introduced into England in 1736; it thrives well

in this country, even in the most barren and exposed situations. In taste, the bark of the Black Birch resembles senega. In America large quantities of sugar are obtained from the sap, but it is of inferior quality to Maple-sugar. There are two varieties of this tree known in England—*Betula nigra laciniata*, with split leaves, and *Betula nigra latifolia*, with broad leaves. The timber of these trees is hard, fine-grained, and of great value.

The Cherry Birch (*Betula lenta*) is also a native of America. It grows best in a rich, moist, light soil, in a free, open situation. Its usual height is 60 feet. The bark is black, and the leaves resemble those of the Cherry tree. The catkins are without peduncles, and consist of simple undivided scales. The bark and buds have an almond-like flavour, and the wood emits a fragrant odour. The sap is used in a similar manner to that of the common Birch. The Cherry Birch yields the timber known as "mountain Mahogany," and the volatile oil, called "oil of winter green," is derived from its bark.

The Marsh Birch (*Betula nana*) is indigenous to the

Alps of Lapland and the marshy lowlands of Sweden, Norway, Russia, Poland, and Switzerland; it is also the only tree found in Iceland. It is a mere shrub, and seldom exceeds 4 or 5 feet in height. The stem is creeping, and the branches are very numerous. The bark when young is reddish in colour, but when old it turns a bright silver hue. The roots consist of long red fibres, which spread widely in the ground; the leaves are small, almost oval, and deeply serrated. Like those of the White Birch, they yield a fine yellow dye. The catkins have no

The Birch.

peduncles, and are placed in the angles formed by the leaves with the twigs. The seeds are numerous, and form the favourite diet of the lemming and white partridge. In Sweden, the branches of this tree are much used by the peasantry as fire-wood; the dense smoke which they emit drives away the gnats, which at certain seasons of the year infest the houses and farm-yards of that country.

The Dwarf Birch (*Betula pumila*) is a native of North America, and was introduced into England, in 1762, by Mr. James Gordon. It seldom exceeds 7 feet in height. The leaves are twice as large as those of the Marsh Birch, ovate, deeply serrated, and lanate upon both sides. The branches are covered to the extremities with a fine woolly substance. The roots are long, red, and strong, and their wood is of considerable value for inlaying work.

The Nepalese Birch (*Betula utilis*) is a native of Northern India; its bark is used in India as packing material, and for lining the tubes of hookahs.

The Paper Birch (*Betula papyracea*) is a native of North America, in the northern parts of which it forms extensive forests. Its bark is exceedingly tough, and is used by the Indians for paper, packing material, tents, canvas, and baskets.

Like all other forest trees, the Birch has its enemies and inhabitants; these are chiefly insects of which the following are the principal:—*Tachyptera antiopa*, *Geometra betularia*, *Tinea proximella*, *Hesperia betulæ*, and *Tortrix solandria*. *Bombyx betulæfolia* is not a denizen of this tree, but has received its name merely from the resemblance that its wings bear to the leaf of the Birch.

JOHN HUTCHINSON, M.A.

NEW EARLY-FLOWERING TREES AND SHRUBS.

THE following ornamental varieties of the class usually known as fruit trees are now showing most abundant promise of blossom with me, some of them for the first time. Of the latter I shall have something to say hereafter; but in the meantime some short account of some of the varieties already known to me may not, I hope, prove unwelcome to your readers, as I think that if these beautiful and free-flowering shrubs were better known than they now seem to be, even in the best English nursery gardens, they would be much more extensively cultivated than they at present are. Nearly all the varieties which I grow I received from Belgium. First I would notice *Malus florabunda*, so beautifully figured in the fifteenth volume of Van Houtte's "*Flore des Serres*" by a series of one single and two double plates, the first giving a branchlet in full flower of the natural size, and most faithfully coloured; the first double plate represents the whole tree covered with rosy buds just about to burst, and the second double plate the whole tree covered from top to bottom with its wreaths of rose-coloured blossoms. This, when seen in full perfection, is as beautiful as anything of the kind I have ever seen or heard of in this country. Of this *Malus* there seem to me to be two varieties, as, when first I received it from Ghent about four or five years ago, I got two plants nominally the same, but which proved, as they grew and developed their characteristics, to be quite different—at all events, in habit of growth—as the one grew straight upwards, and is now some 12 or 14 feet high, while the other spread laterally with a decided tendency to weep, and is now not more than 4 feet high, but three times that measurement in circumference. This last has flowered profusely each spring for the past three years, but the upright-growing variety did not flower at all for the first three years; last year it produced a stray bunch or two of bloom, but this year I am happy to see every young shoot furnished with its bunch of bloom, just as in the other and more weeping variety. Next I would mention *Malus baccata flore roseo pleno*, beautifully figured in a double plate at the end of the nineteenth volume of Van Houtte's "*Flore des Serres*." This is the earliest to open its blossoms of any variety with which I am acquainted, and is extremely free-blooming and a very fine plant. Another beautiful and tolerably free-blooming plant is the *Cerasus caproniana ranunculiflora*, a shrub which produces large double pure white flowers, and is by far the finest double Cherry which I have as yet seen; it is figured in the seventeenth volume of Van Houtte's work (p. 159). Two other fine Cherries are *Cerasus Watererii*, white-edged, with pale rose colour, and *Cerasus Sieboldii flore roseo pleno*, a large blush-coloured semi-double flower. Some four years ago I received also from Ghent a plant under the name of *Prunus virgata*, which, up to this season, has done nothing but grow, sending up, principally from the root, numerous slight switchy shoots, but never showing any sign of blooming, which was the more disappointing, as it was described to me as a beautiful double rose-

coloured variety. This spring I am pleased to notice on the extreme points of some of the young growths of last season one or two full and double-looking buds, somewhat resembling those of the lovely *Prunus triloba* (which, with me, is unfortunately an extremely shy bloomer), but deeper in colour. It is to be hoped when these expand they will be as beautiful as they have been said to be. Another curious Japanese variety of *Prunus* is that described and figured in Siebold and Zuccarini's "*Flora Japonica*," under the name of *Prunus tomentosa*. This variety is chiefly valuable, not for the beauty of its blossoms, which, though profusely produced, are dull blush in colour and insignificant in size; but, for its beautifully bright scarlet fruit, which resembles a large and shining haw or *Cotoneaster* berry in size and appearance, with a white spot in the centre of each side. I cannot, however, get it to set its fruit satisfactorily, having only succeeded in getting one or two fruits during the three years I have had it, although I have tried it both in a pot in the house and in the open air, where it now is, and also endeavoured to artificially fertilise the blossoms of which the plant each year produces a large quantity. The other varieties I expect to bloom this season, for the first time, are named respectively as follows:—*Malus spectabilis flore albo pleno*, double white Apple; *M. sibirica coccinea*, *M. toringio major*, *M. tenori flore carneo pleno*, and *Cerasus umbraculifera*, a dwarf bush-growing variety. As I see that Mr. Van Houtte, in his last Catalogue, No. 158—F. F., page 93, offers good plants of the lovely *Malus florabunda* at the very moderate price of 10d. each, or 6s. 6d. a dozen, no one fond of flowering shrubs need or indeed should be any longer without this beautiful plant.

W. E. GUMBLETON.

Belgrove, Queenstown, County Cork.

Gum Copal Trees.—A short report from Zanzibar, by Captain Elton, on the Gum Copal trees of Dar-es-Salam, has just been printed among the Parliamentary papers. Captain Elton was astonished at the number and size of these trees, which far exceeded anything he had before imagined. On stripping off the bark, the gum was found deposited in many places between it and the wood in a liquid form. The trees are suffering from the attacks of swarms of ants and other insects, and are being slowly but surely destroyed. They are all festooned with the long intertwined ropes of the india-rubber Uiana, the thickly-matted cords of which, pendent from the main limbs and knotted into a sort of rigging, become an easy means of ascent to the natives looking for the resinous deposits on the branches. This india-rubber was worked rather extensively here at one time, but was soon given up as unprofitable, in consequence of the number of slave-lads carried off by leopards.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The White Pine as a Hedge Plant.—This is used in New England for this purpose, and on account of its brighter and never changing green it has a finer appearance than either the Hemlock Spruce or American *Arbor-vitæ*. For dry sandy soil it is peculiarly adapted.

Walnut Burls.—A burl is a disease—an excrescence which grows out from the trunk of a Walnut tree, and which is often found of an enormous size, sometimes a ton in weight. The choicest ones contain a beautiful and variegated grain, and they have been known to command high prices.

Should Seeds of Styrax be Soaked or Cracked.—I have this day received from the Continent the seeds of a new *Styrax* from the mountains of California, and as the shells of the seeds (which are most of them larger than a full-sized Pea) seem extremely hard, I shall be glad to know from some of your readers, who have experience in these matters, what is the best course to adopt to ensure vegetation—whether the seeds should be soaked in water, or whether the hard shells should be broken and only the kernels sown.—W. E. G.

Tree Nurseries of the World.—The Romans were the first of original propagators and disseminators. To them France and England are indebted for the first introduction of choice varieties of fruits, and to the missionaries of the Romish Church is largely due the introduction of choice varieties everywhere. France probably has grown and distributed from her commercial nurseries more trees than any other nation, and to-day she is supposed to have 200,000 acres in such nurseries. There is no estimate of the actual extent of German nursery gardens at hand. The United States commenced commercial nurseries about 1791, and from 1810 to 1820 had perhaps 200 acres. According to "*Moore's Rural New Yorker*," it may now be estimated that 500,000 acres are devoted to commercial tree growing in the United States.

Eucalyptus globulus in the Riviera.—I was glad to see this noble Australian tree flowering so abundantly in the Riviera during January of the present year. I saw it in flower at San Remo, Nice, Cannes, and Hieres. It appears perfectly acclimatised, attaining to the height of 30 to 40 feet, and covered thus early in the year with its beautiful blossoms. Belonging, as it does, to the Myrtaceæ, it has much of the perfume of this group, and its fine scimitar-like pendent leaves exhale a rich resinous aroma, which is considered as a counteractant of the malaria so prevalent in the marshy tracts of Italy, being abundantly planted about Rome to effect this very purpose; and, as it readily adapts itself to the soil and climate, it may prove a valuable antiseptic. The inflorescence, as in so many of the Myrtlewoods, consists of a crown of stamens covered before expansion by a closely-fitting white lid of a globular form. We thus see the appropriateness of both the generic and specific name as applied to this tree.—PETER INCHBALD, *The Lodge, Hovingham, York.*

SURFACE DRESSINGS.

THESE are generally given to enrich impoverished soil, and barren fruit trees are often brought into fertility by means of them. When the roots are down in an uncongenial sub-soil top-dressings will not bring them to the surface, but they will induce the formation of young fibres there, and thus improve the state of the tree compared with what it was when its sustenance was wholly derived from the tap roots. Top-dressings should always be placed in contact with some of the roots; for, unless this is effected, they are almost useless. Roots have a tendency to go down and embed themselves in the richest soil, but I have never found any of them pushing up towards a rich top-dressing, that is, if they had to pass through a stratum of matter which they disliked. It is not an uncommon thing, when turning out plants from pots which have been top-dressed some time previously, to find the top-dressing fall clean away from the entire ball. This is the result of not incorporating it thoroughly with the old soil, and of not putting the mixture well round the roots. The result is the same in the case of fruit trees, and in all other instances in which top-dressing is not done properly. Of course, in these cases, when the material used is very rich, much of the fertilising principle is washed down amongst the bottom roots, but the advantages which attend a free and copious surface rooting are lost. I know instances in which Vine borders, both inside and out, are heavily top-dressed every autumn with rich materials, and yet not a root is to be seen when they are annually turned up. Vines in such a condition might be much improved by having the main portion of their roots brought within a few inches of the surface, but of this they have very little chance until fresh top-dressings are placed directly in contact with them. Many plants are grown one year in pots, from which they cannot be removed the next. Vines, potted and grown on in their fruiting pots this season must be kept in the same pots next year until they fruit. A quantity of loose exhausted soil is generally found on the surface at the end of the season, and this should not be permitted to remain. On the contrary, it should be removed, and a top-dressing put in its place, and in a position where the roots can take possession of, and utilise it when it is most needed. The removal of a few leaves from the neck of a Pine-apple plant, shortly before the fruit appears, and the application of a good top-dressing always does good—the roots run freely into it, and it is ultimately of great assistance in finishing off the fruit. Melons and Cucumbers are much benefited by top-dressing. When the latter have produced their first crop, a second, quite equal to the first, may be obtained by adding a good top-dressing to the old plants, an application which renews their vigour, and gives them a further lease of fruitful life. Probably no plant will recognise and repay a top-dressing better than an old exhausted Peach or Nectarine tree. I have seen old trees of these kinds, scarcely capable of bearing a single fruit in midsummer, induced not only to bear heavily at that season, but come in as early croppers in May through the aid of a rich top-dressing. It has the same salutary effect on all fruit-bearing trees, whether they are confined to the inside of a house or exposed on open walls. Such trees, however, should not be top-dressed every year, as that would too much disturb their roots, which should be near the surface. Flowering plants in pots are equally benefited by top-dressing. Large plants of Camellias, firmly rooted into pots or tubs, and whose life would be endangered by a complete shift, may, by a suitable surfacing, have years of vigorous life and usefulness added to their career, which would otherwise be passed in drooping decline, and Azaleas may be benefited in the same way. Small quick-growing plants are seldom top-dressed; they generally can be conveniently re-potted, when no surfacing is needed. With cottagers and amateurs, the re-potting of their window-plants is often considered to be a dangerous operation, and many of these plants are, for this reason, allowed to dwindle for years in the same soil and pot. Those who are afraid to re-pot annually, should substitute a thorough top-dressing; and if the drainage below be efficient they will soon be repaid for their trouble. There are not a great many vegetables that need top-dressing at any time. Earthing-up may be considered as a form of top-dressing; it induces multiplication and surface-rooting in many plants.

Herb roots are not generally re-planted every year, and their productiveness is greatly enhanced by an annual spring top-dressing. This saves mulching, and I infinitely prefer the former to the latter; for, when a plant, with its roots close to the surface, is mulched, the roots grow freely under it, but their growth is not substantial, and they generally die back as soon as the covering is taken away, and are not at all of the same healthy character as those grown in, and protected by, a suitable top-dressing. I have stated that top-dressing may be accomplished at any time, which it certainly may without injury; but I prefer applying it in most cases before growth is far advanced, in order that it may be made available to assist development.

J. MUIR.

ROAD MAKING.

IN the construction of ordinary highways, the civil engineer, geologically speaking, has before him three things of prime importance—choice of route, nature of gradients as requiring excavation and embankment, and suitability of material for bottoming and macadamising. In Britain, where many of the roads are of ancient date, and were originally intended for pack-horses and not for carriages, they are generally “up hill and down dale” over dry tracts, and very unsuitable for modern requirements. When such roads have to be improved in their gradients, it is usually by a series of “cuttings” and “embankments;” and some skill is required not only in excavating the rock-material, but in seeing how far the whole or any portion of it can be utilised, either in the construction of the road and the embankments, or as an article of sale in the neighbourhood—be it sandstone, limestone, greenstone, or granite. But where a new route of easy gradients has to be chosen, the engineer, from his geological knowledge of the district, may often show great skill in avoiding expensive cuttings; in making cuttings, which, though expensive, may more than repay themselves by the utilisation of the excavated rocks; and in keeping clear of peaty and marshy hollows for his embankments, which are never stable till the soft boggy sludge is squeezed out, as it were, by three or four times the amount of carried material that would have been required on a firmer bottom. In choosing a new route, shortness, easy gradients, and the requirements of the district are, no doubt, prime considerations; but in some instances it may be worth while to deviate from the selected track in order to come in closer proximity to quarries, clay-pits, and coal-fields—the increased traffic arising from which may become a source of income for the permanent maintenance of the highway. Highways are the arteries of a country’s commerce, and a good system of roads suitable for all requirements, present and prospective, is one of the most essential elements of national prosperity and development.

Road Cuttings.

Having selected a route, the engineer has next to enquire what excavations, what embankments, and what bridges will be necessary to render the road of easy traction as to gradients. In the matter of excavation, it requires some skill, according as the cutting may be through tough boulder-clay—through an admixture of drift sands and clays, which are apt to slip by the percolation of water—through greenstones and basalts, which, though expensive to remove, may be utilised as road-material—or through sandstones and limestones, which may be applied to the erection of bridges and retaining walls. Some acquaintance with the structure of rocks will also be of use to the engineer, in as far as these may be jointed or full of “backs and cutters,” like some limestones; columnar or sub-columnar, like basalts and greenstones; tabular, as granites; or in alternate hard and soft strata, as sandstones and shales. Every formation has its own lie and structure, and excavating in accordance with these is always the cheapest and most expeditious method. Where the material is of uniform character, little care is needed either as regards retaining walls or slope of excavation; but where the material is of unequal durability, as alternations of sands and clays, of sandstones, shales, and clays, the weathering of the softer beds is sure to ensue, and should be protected by facing-up immediately after excavation. From want of this precaution—and especially in railway cuttings—much after-expense has often been entailed, and that not till obstructions and accidents have happened through slips and falls—such contingencies of themselves costing ten times the amount of any walling-up that might have been at first adopted. Some care is also necessary when excavations pass through strata at high angles, so as to prevent slips from the rising side; and when water-bearing beds occur, free egress must be made for the outflow, which otherwise would, in process of time, bring down the strongest retaining wall. Where cuttings pass through rocks suitable for building or for roads, a free face should be kept, if possible, for

future quarrying—the situation being so available, not only for the working, but for the removal of the quarried material. A quarry in close proximity to a road or railway is always more valuable (other things being equal) than one situated at a distance, the expense of cartage, loading, and unloading adding considerably to the price of the raised materials. We have spoken of road-routes as they usually occur in the British Islands; but in mountainous countries a great deal of extra skill and precaution has to be exercised in winding and zigzagging, in scarping or tunnelling precipices, and in providing ample and substantial water-courses and culverts—the heavy rainfalls of these heights, and their steep inclinations, subjecting the highways to torrential forces altogether unknown in lowland regions.

Embankments and Bridges.

In the matter of embankments, little geological knowledge is required beyond ascertaining the nature of the foundations on which they are to rest, the facility with which the banking material may be obtained, and the angle of repose at which such material is likely to remain. Embankments across marshes and peat-mosses are frequently of difficult execution, requiring not only a vast amount of material, but sometimes subsiding for months and years till the soft underlying bed be thoroughly squeezed out or compressed. Besides calculating so that excavation and embankment shall balance each other as nearly as possible, the side-slopes or angle of repose should be studied, blocks and hard rocky debris resting at inclinations at which sand, clay, and soft earthy substances could not possibly remain. Embankments are artificial rock-formations, and the more uniformly the material can be “tipped” and assorted, the more compact, impervious to water, and less liable to “sits” and slips, will the mound become. As with embankments so with bridges; their foundations require similar attention, and though their construction be chiefly a matter of masonry, yet some geological acquaintance with the situation and nature of the materials to be employed cannot fail to be of advantage. Whatever the nature of the bridge, whether stone or girder, everything depends upon a secure foundation; and this, again, depends on the geological nature of the material to be built upon, be it solid rock, tough firm clay, or soft silts requiring concrete, piles, or other device to secure stability. The alluvia in river-valleys are often of great depth and of treacherous nature; and it is frequently more judicious to make a deviation to secure a rocky foundation than to persevere in a straight line over such superficial accumulations.

Road Materials.

Touchning road materials, a great variety of substances are used in Britain, but the best of them will not make a smooth and durable highway unless they be laid on a good bottoming of rubble-stones, and these again on a well-drained surface. On a wet soil the road-metal sinks, becomes uneven, and wears irregularly, while in winter the moisture freezes and expands, and when thaw comes the surface is broken up and the consistency of the metal destroyed. In all cases the scarf-skin of agricultural soil should be removed, and, if not needed for levelling-up, can be readily disposed of on the adjacent farms for composts and admixture. In some districts where granites abound they are broken for road metal, but if large-grained and highly felspathic they are easily crushed and reduced to clay. In others porphyries and felstones are employed, and many of these, from their hardness and toughness, stand well, though somewhat expensive in the breaking. In others, again, where traps prevail, greenstones and basalts are largely used, and when broken to proper size make by far the smoothest and most durable roadway. Of course there is great variety among these greenstones, but unless among the softer and more felspathic sorts, they are not only durable but cheaply procured. In some districts the harder pebbles (chiefly of quartz, porphyry, granite, &c.) from river-channels and the sea-shore are employed, in others the harder and more silicious limestones and sandstone; in some the flints from the chalk, and in others near blast-furnaces the slag is broken by crushing machines, and makes a fair, though not very durable, metal. In all cases of macadamising, thorough drainage and a good bottoming of rough rubble is indispensable; and when the metal is laid on, a heavy rolling down and consolidation with some sharp gravelly binding is equally necessary. Basalts, greenstone, felstones, and felstone-porphyrries, make the smoothest and most durable metal, and now, since the introduction of efficient crushing-machines, should be sought after by the road-maker, even though requiring to be brought from considerable distances. In the construction of street thoroughfares subjected to heavy and continuous traffic, and where macadamising would be all mud in winter and dust in summer, recourse must be had to causewaying either in rubble or in regular courses. The former may do for by-streets where the traffic is light; but for the great public thoroughfares of a commercial town nothing will serve save coursed blocks of granite, porphyry, or greenstones. Wooden blocks, concrete, and

asphalte are at their best but indifferent substitutes, and wholly unsuited where the gradients are steep or even considerable. Granites like those of Aberdeen, Argyle, Dalbeattie, Creetown, Wicklow, the Channel Islands, &c., are largely used in all the thoroughfares of our principal cities, and make clean and durable streets; but some kinds of porphyry, like that from the Moorfoot Hills, and employed in Edinburgh, are harder and tougher, though from their tendency to wear smooth they require to be laid down in narrower courses. Greenstones are also largely used, and when properly coursed and bedded are almost as durable as granite. Good samples of greenstone-causewaying may be seen in Edinburgh (Ratho, Dalmahoy Crags, and Corstophine Hills), in Glasgow (Croy and Kilpatrick Hills), in Newcastle (Christon Bank and Wall), in Leeds (Richmond), and, indeed, in most of our large towns where the rock can be obtained at a cheaper rate than granite. In some instances quartzites and hard silicious sandstones are employed: they stand well, but, from their tendency to wear smooth and slippery, require to be laid, like the Moorfoot porphyry, in narrow courses. For the footpaths of our towns flagstones are in great request, and some of them held in high estimation. Those from the lower old red sandstone of Caithness are extremely hard and durable, and can be obtained of great size, and from 1 to 9 or 10 inches in thickness. Being very hard and close in texture they are apt to become too smooth; some contain nodules of iron sulphide which resist wear, and render the surface irregular and somewhat dangerous, and many of the harder and thinner sorts are apt to crack unless carefully bedded, as all of them require to be. They are, however, impervious, or nearly so, to water, and make a clean and easily-kept footpath. About 10,000 tons are annually exported from the county, at a value of between £4,000 and £5,000. Those procured from the lower old red of Forfarshire and Perthshire enjoy also a high reputation; but from their softer, more laminated, and absorbent nature, are better fitted for inside than for outside pavements. Local supplies of flagstones are also obtained from the coal formation in several counties (Fife, Edinburgh, and Lanark); but those from the millstone grit and Gannister beds of Yorkshire and Derbyshire are perhaps the best and most durable, and capable of being raised of great size and of any thickness. Supplies are also obtained from the new red sandstone of Dumfriesshire and Cumberland, which are of fine even grain, and though rather soft, wear well and equably. Flags of fair quality are also raised from the middle oolite, and from the Wealden in Sussex, but they want the largeness, smoothness of surface, and compactness of texture which characterise those from the old and new red sandstones. What is wanted in a good flagstone is variety in thickness and size, a straight and even surface or bedding, and a non-absorbent and compact texture—laminated varieties being apt to split or peel off under the influence of frost and moisture. In some country towns the footpaths are neatly laid with pebble-stones; and in the suburbs of Edinburgh the larger chips obtained in dressing the causeway-blocks are closely set on edge and beaten down to a smooth surface, thereby making a firm and durable material under the name of “Hornising,” after a surveyor of the name of Horne. For kerb-stones, granite, greenstone, and some of the harder sandstones and limestones, have long been used. The granites of Aberdeen, Kirkcudbright, Wigtown, and Wicklow, make excellent material; some of the hornblendic greenstones, as those of Queensferry on the Forth, and of Corstophine and Ratho near Edinburgh, are equally suitable, and more cheaply tooled; while many of the harder limestones (Derby, York, Westmoreland, and Devon) square well, and are extensively employed in their respective areas. In some towns sandstones on edge are employed; but these, unless hard and uniform in texture, are apt to split up under the weather, and wear irregularly. A straight, durable, and well-set kerbstone is indispensable to a good street, not only in retaining the flagstones and maintaining the gutters, but in imparting an appearance of finish and stability to all the lines and turnings.—“Economic Geology.”

Ice for Preserving Fruit.—The introduction of modern fruit-preserving houses, wherein, by means of ice, a low temperature is maintained at all seasons, is of real benefit to horticulture. The Nice patent appears to have been the first really practical application of the system, and so far as we understand its utility, is very deficient, not alone in construction, but in the material requisite to keep the atmosphere dry and pure. A very simple arrangement of this character is in use at Reading, where the fruit is preserved for a year, coming out as fresh as when first put in. Others at various points in New York State are also in good working order, and from present appearances will prove successful. The chief requisites in this system of preserving vegetables and fruits are a low temperature, thorough ventilation, and moderate cost.—“New York Tribune.”

THE NEW ZEALAND FLAX IN IRELAND.

PEOPLE about London have no idea of the great value of the New Zealand Flax as an outdoor ornament. In London we value it highly for the conservatory or winter garden, or for room decoration; but, however well grown it may be in pots or tubs, we never get from these a good idea of the fine aspect of the plant when well-grown in the open air and in a favourable climate. In the south and west of England this Flax is frequently hardy out-of-doors, but the finest plants we have seen are in Ireland, where it thrives remarkably. Last autumn, in Lord Meath's garden at Killruddery, Wicklow, we saw the fine plant of which the accompanying is an illustration. It occurs in the kitchen garden there, and our engraver has taken the liberty of associating it with less prosaic surroundings. Remarkable as the specimen appears to be, judging from the illustration, it is more so in reality. Mr. Turner, writing to us from Killruddery, states that the plant is 12 feet high and 48 feet in circumference, one leaf measuring 14 feet in length. In New Zealand this plant may be seen

the best prepared Flax, which they scrape with sharp shells or knives, and, although only a comparatively small quantity can be thus rendered fit for the European market, it nevertheless invariably brings the highest prices. Many mills, however, are still worked, and no inconsiderable quantity of the Flax reaches England annually, in spite of the difficulty which has been alluded to, and the removal of which would render the Flax an article of export second only in value to the wool of the colony.

ORNAMENTAL PLANTS.*

ONE great drawback to the extended distribution of many highly ornamental plants is the difficulty of adequately describing their peculiar beauty. One cannot possibly form a fair opinion of their merits from any verbal account, however concise and correct it may be. On the other hand, illustrations, more especially those that are coloured, at once enable us to form a just conception of the shape, colour, and general appearance of any plant that may thus be figured. The publication we are now noticing, which is the joint

New Zealand Flax at Killruddery, co. Wicklow.

covering acres of ground throughout the three islands, over which it is, in places, plentifully distributed. It appears to grow most profusely in damp alluvial ground—often upon the banks of rivers and rivulets, and sometimes at very considerable altitudes. The Maoris were, and indeed still are, in the habit of obtaining from the leaves a most valuable fibre, which, when thoroughly freed by hand-scraping from the resinous gum which surrounds it, is of a soft silky appearance and texture, and of unusual strength. Numberless attempts have also been made by colonists to discover some method of cleaning this Flax, and a great many skutching mills have been erected at various times, both in the north and middle islands, with this object. At one time it was considered that the secret had been discovered in the use of ammonia, but, either from the expensive nature of this chemical when used on a large scale, or from its practical failure to accomplish any valuable results, the process was never universally adopted. The natives, even now, produce

work of MM. Cogniaux and Elie Marchal, and edited by M. Alexis Dallièrè, is, for this reason, a valuable addition to botanical and horticultural literature, inasmuch as it contains between fifty and sixty unusually large plates—the majority of them beautifully coloured—of many plants which have never been correctly represented before, besides those of which illustrations are somewhat more common. In addition to this each plate is accompanied by excellent botanical, historical, and horticultural descriptions, which render the work a very complete one.

Frosty Weather and Lake Subsidence.—When a sharp frost sets in in the Lake district the level of the water in the larger lakes quickly falls as in a dry summer. So noticeable is this, that the boatmen and fishermen say, “the frost nips the water off the lake.” The real reasons are, I believe, obvious. In frosty weather the rainfall ceases, the drainage and the rivulets (the

* “Les Plantes Ornementales à Feuillage Panaché et Coloré.” Edité par Alexis Dallièrè, et rédigé par Alfred Cogniaux et Elie Marchal.

feeders of the rivers) on the mountains are very quickly frozen up, the outflow from the lake all the time going on freely unimpeded by the frost, because the volume of the stream is large, and much nearer the sea-level.—“Science Gossip.”

GARDENING FOR THE WEEK.

Indoor Fruit Department.

Vines.—When all the soil for planting these has been mixed up, as directed last week, the formation of the border may be proceeded with. Drainage must form the lowest layer, and for this nothing less than 6 inches of roughly broken bricks or stones is sufficient; if the bottom beneath the drainage is soft, a thin layer of concrete to begin with is an advantage. In a lean-to building the bottom should be made to slope from the back to the extreme front; where span-roofed it should drop both ways from the centre. A large main drain should be laid along the margin of the slope, so as to convey away superfluous water at once; small 4-inch tiles, running across the border horizontally into the main drain, is a sure means of drainage. A few of the roughest turves should be placed, grassy side down, over the entire drainage. The soil may then be filled in, mixing the rough with the fine throughout; 2½ feet is a very serviceable depth for the soil, but, being new, round, and fresh it generally settles down from 4 to 6 inches from its original height, so that the soil should be 3 feet deep all over the border when first made up. Grapes on the earliest pot Vines will soon be changing colour, and no opportunity must be lost to admit a circulation of fresh dry air after this has begun, for, when ripened in a close atmosphere, they are generally deficient in flavour. Manure-water should not be given to Grapes colouring, but clean water must be regularly supplied when needed. Vine eyes will now be pushing freely, and a dewing overhead every afternoon assists the leaf-expansion; 5° more bottom-heat may be given as soon as a few roots are formed.

Pines.—The temperature for newly-potted plants should be about 70° at night and 85° during the day before admitting air, which should be with the top ventilators for a time. Humidity must be copiously kept up night and day, or the leaves will shrivel before roots are formed to prevent it; and a syringing overhead occasionally is of much benefit to them. Successional Smooths, and other sorts, intended to succeed the Queens as fruiterers, should be re-plunged after those newly potted are finished with. If they have been growing closely together previously, they should be plunged wide enough to admit of their unrestricted development. The glass and wood-work must be washed, and the walls lime-washed, as the plants are taken out, and before they are re-plunged; such operations cannot be easily performed afterwards. Do not let Queens, now rapidly swelling their fruit, suffer through want of water. In a general way, once a week is not too often to water them; but, if necessary, it may be given twice during that time, or withheld altogether.—J. MUIR.

Peaches.—The thinning of the fruit in the early house should be attended to as soon as it can be seen which fruits are taking the lead in size, and this can be observed when they have well burst the tube of the faded flowers. It is wasting the energies of the trees to allow the fruit to become as large as Peas before thinning, which, if done vigorously, will give the fruits left a better chance of swelling and stoning, and will induce them to grow quicker and larger than if a quantity, which must eventually come off, were left to compete with them at this early stage. Another good watering should be given to those planted in inside borders, as Peach trees in full leaf can scarcely have too much water at this period, provided it be certain that there is free drainage underneath. Proceed also with the disbudding of the trees, gradually removing the shoots which are badly placed, and thinning out those on the underside of the branches first; and where the young shoots are generally overcrowded at the base of the bearing wood. I recommend a system of pinching as well as thinning, that is, disbudding where overcrowded, and pinching in the shoots wherever there is room for them, always training in young wood in the usual way. Where the branches have been left too thick at the winter pruning, the present is a good time to remove some of them, in order to give room for young wood for another year, as choice can now be made of those branches which are least fertile. Overcrowding is sure to end in weak growth, and ultimately in badly-ripened wood. During dull weather a little fire-heat must be maintained in succession houses to cause a free circulation of air about the blossoms. A damp, cold atmosphere is the very worst condition for setting the fruit. Moisture may be given, and the syringe may be used even freely, provided there be a warm, brisk atmosphere maintained. The blossom buds are now swelling fast

in cool unheated houses, and the borders must be thoroughly moistened throughout. The trees will open their blossoms quicker when the borders are dry, because the soil is warmer, but the fruit will not set so freely. A border thoroughly wetted now will have the effect of retarding the blossom, but also of causing a more healthy setting of the fruit. Checking the bloom at this season will eventually be found a decided gain. Give air to such houses early in the day to dry and thoroughly ventilate the interior, shutting up early in the afternoon to husband sun-heat.

Melons.—Recent dull weather has been unfavourable to the healthy progress of early Melons; without a brisk bottom-heat of 80° their development will be slow, but, to give much fire heat in the absence of sun, causes watery growth, and is a doubtful practice. It is preferable to husband the strength of the plants until the return of bright weather. Although all the light possible is necessary at this season to strengthen the growth, they will, on sudden outbursts of sunshine at midday, require a little shade to prevent scorching, to which Melons are liable at this season after dull weather. The sun must, however, be allowed to strike on the soil as much as possible; this can always be managed by using small separate screens for each plant instead of those covering the whole house or pit. As the plants advance they will require to be pinched to cause them to throw out lateral and fruitful growth, but this will not be necessary until they have gained 2 or 3 feet up the wires, for these remarks apply to Melons grown in heated houses with wires strained close to the glass.—W. D. C.

Flower Garden and Pleasure Grounds.

Pot off singly the rooted cuttings of bedding Pelargoniums of all kinds in order to have strong well-furnished plants for turning into the flower beds at the proper season. Keep the plants, for some time after they have been potted, in a warm close atmosphere until they become somewhat established and their roots reach to the sides of the pots, when they may be transferred to frames or cold pits, and their place taken by other newly-potted plants. In most gardens every inch of room under glass will now be required; and, to economise space as much as possible, such half-hardy species as the various bedding Calceolarias, and similar plants, which may have been inserted as cuttings during the months of September and October, and which may have been wintered in store pots, in pits or frames, and will now be well rooted, may be shaken out of the pots and pricked out into beds of light rich soil in frames, turf pits, or even into a prepared trench, so that they can have, when necessary, the protection of mats or other materials. From this the plants can be readily transferred to the flower beds, early in May, with little or no check. Plants treated in this manner generally succeed better than if turned out of small pots. Verbenas, Gazanias, and other species of bedding plants may now be subjected to this treatment with much success. Where succulent plants are likely to be extensively used as edging plants to flower beds and for forming divisional lines in carpet bedding, such species as the *Echeveria secunda glauca*, *Sempervivum californicum*, &c., which may have been wintered in tufts or patches, should now be divided and pricked out singly in pans or boxes. A few seeds of the Ten Week and German Stock may now be sown in a gentle heat for early flowering, together with a few climbing and other annuals, for special purposes, such as the *Cobæa scandens*, *Lithospermum*, *Maurandias*, &c; and, if not already done, no time should be lost in sowing, in pans, the blue *Lobelia* and the Golden Feather *Pyrethrum*; while its rival, the *Stellaria graminea aurea*, should be increased by cuttings or divisions. Most hardy herbaceous plants will now be showing themselves above ground, and the soil should be enriched if necessary with some manure, or fresh soil may be added to it, and carefully forked or dug in. A well-arranged herbaceous border ought to be an indispensable feature in every garden, affording, as it ought, a succession of flowers from early spring-time until nearly the end of the year; and, as the present is a very favourable time for introducing fresh and valuable varieties into this department, the claims of many of the new Phloxes, Delphiniums, Dianthus, Lilliums, &c., are well worthy of consideration. The presence of broad-leaved weeds, such as the Plantain, very frequently detracts greatly from the otherwise pleasing appearance of lawns, Grass belts, &c., and there is now a good opportunity for extracting them. This is easily accomplished by thrusting a sharp knife under the plant, so as to sever the roots an inch or more below the surface of the ground, when the plants may be drawn out without disturbing the soil in the least degree; and if a pinch of salt be then dropped into the hole, the destruction of the intruding plant may be considered as completed. The lawn should afterwards be swept and well-rolled. As before, long mowing may be found to be necessary, and it is generally considered advisable to pass the scythe at least once over lawns, &c., before the mowing machine is brought into action.—P. GRIEVE, *Culford, Bury St. Edmunds.*

Forcing Roses.

The absence of bright weather affects the successful forcing of the Rose equally, if not more, than that of any plant with which I am acquainted. My experience of forcing Roses, and that is not inconsiderable, is that Roses, if to bloom in December, must be forced at the expense of considerable loss of plants, and the only result is a quantity of incipient ill-ripened wood and premature buds, and more frequently no buds at all, and I contend that at that period of the year, from an almost entire absence of solar heat, it is impossible to get anything like true colour or character into the blooms, which are too few to merit the expense attendant on their production. I now refer to the Hybrid Perpetual class, and my experience of the Duke of Edinburgh and Charles Lefèvre is that they are not Roses to recommend for early forcing when there are so many other kinds that supersede them. Further, I have found that to have the Hybrid Perpetual section in bloom at the end of January at the earliest, it is necessary that the plants be established in pots the previous season. This is a very important matter, as, by having them already established, there is a clear gain of a fortnight, or even three weeks, where the earliest kinds are employed, as the plant can be introduced into a gentle heat at once—treatment that I should certainly not advise in the case of plants freshly lifted from the ground and potted up for the occasion. Among Teas, I find that Madame Falcot, Safrano, and Devoniensis, as regards profusion and quality of buds, are the three best varieties for pots; and that Maréchal Niel and Gloire de Dijon are best planted out. I have treated the two latter in this way, and I expect about Easter to cut from 2,000 to 3,000 buds. Of the Hybrid Perpetual class, I have nearly 2,000 in one house in different stages of growth, and I find the following selection for early forcing to be the best:—Light varieties—John Hopper, Ann Alexiff, Victor Verdier, Mlle. Eugène Verdier, and La France; dark varieties—Madame Moreau, Beauty of Waltham, Fisher Holmes, Sénateur Vaisse, and Antoine Ducher. Any of your correspondents, contemplating forcing Roses this season with established plants, cannot well err in adopting the above selection, as, if not excited into growth too rapidly, there need be no fear, in a genial humid atmosphere, with a judicious application of air, that the plants will not set well for bloom.—J. D. G.

Orchids.

All newly-potted plants will require great care as regards watering, so as not to get the fresh material into a sodden condition before they have advanced considerably in growth, or until they have acquired a vigorous root action. A sprinkle with the syringe once a day, and twice on bright days, will, however, tend very much to keep them from shrivelling. All plants that require potting should have that attention as soon as possible. Plants to be top-dressed should stand in water half-an-hour before that is done; for, when thus situated, wood-lice or cockroaches will come to the surface, and may be destroyed. If this is neglected, these pests will soon destroy the young roots. Plants potted in the early part of last month should have a thin layer of Sphagnum in a fresh living state, cut about 1 inch in length, and placed on the surface. This helps to keep the soil fresh, and prevents green matter from making its appearance, which it always does where water has to be used freely. It will now be necessary to have all blinds seen to and fixed in their different places. The East India-house will require shading two or three hours on bright days, and the greater part of the Odontoglossums like heavy shading throughout the summer months. *O. citrosmum*, *O. Lepardinum*, *O. Rossii*, *Oncidium tigrinum*, *Cattleya maxima*, *C. speciosissima*, *Lælia majalis*, *L. albida*, *L. autumnalis*, *L. anceps*, *Barkerias*, *Epidendrum atro-purpureum*, *E. nemorale*, will all grow and flower without shade; but, in that case, they must be supplied with a greater quantity of water. Dendrobiums started into growth will now do well if placed in an early Vinery, where they can have the full benefit of the syringe. Plants of *Cœlogyne cristata*, that have flowered, should be removed to a cooler part of the house, where very little water must be given them—only, in fact, enough to keep them from shrivelling. It will be necessary to fumigate often this month, in order to keep down thrips and red-spider. Some Orchids are, however, apt to get injured by the smoke; and these, if they cannot be removed to another house, should be set on the floor. Orchid-houses will now be gay with Dendrobiums, Trichopilias, Cypripediums, Lycastes, Cattleyas, Masdevallias, Phalænopsis, Phajus, Odontoglossums of many kinds, and Vandas.—E. CULLEY, *Ferniehurst*.

Kitchen Garden.

Where large numbers of Asparagus beds exist, their produce might be distributed over a longer period than would otherwise be the case by simply protecting one or two of the beds, without having recourse to artificial heat in any way; although, of course, where the latter, by means of leaves and hot dung, can be obtained in

the alleys, vegetation will be considerably hastened. What I am, however, more especially alluding to is the fostering influence of mere protection in some shape or other. Glass, of course, is best; but, where that is not available, other coverings may be employed for the purpose. Be the coverings what they may, however, they should be taken off every warm sunny day and put on again at night; the object is to secure as much as possible of the sun's warmth, and then by coverings on cold frosty nights and days to prevent or check radiation. The surface of the beds should first be stirred and loosened up with a fork and then raked so as to leave a fine even surface; this should be effected on a fine dry day, as letting the air into the ground at this season dries and warms it considerably. In most places March is the usual month for planting the main crop of Potatoes. In low-lying districts, where spring frosts are very destructive, planting may be deferred till the first or second week in April. In dry hilly situations autumn planting may sometimes be adopted, but one of the principal objections to this is, it deprives the land of the beneficial effects of exposure after breaking it up deeply in winter, which lets the frost into it to pulverise and sweeten it. Where autumn planting is adopted I should only recommend it on very dry soils. So soon as the Potatoes come up in the spring the space between the rows should be deeply stirred with a fork to let in the air. I suppose amongst practical men there cannot be two opinions about the advantages to be derived from a frequent change of seed, especially in small gardens where there is a difficulty in carrying out any given system or rotation of cropping; but in procuring changes of seed Potatoes some pains should be taken to obtain them from a soil different in character to that in which it is intended to plant them, allowing due weight also, independently of the question of soil, to the elevation of the district from which they came. In this way, seed should be obtained from elevated places to plant in low damp situations, and *vice versa*. As a confirmation of the advantages of this, I may instance the large quantities of Scotch seed Potatoes planted annually in the Fens, yielding, as they do, the most satisfactory results. I am quite sure an intelligent application of this principle will be the means of so largely increasing the produce as to more than compensate for any additional expense incurred. Make a small sowing of Beet in boxes, in a gentle heat, to be transplanted in April for early use. Early sown Beet is liable to run to seed; therefore, unless the consumption is large, no great quantity need be sown just yet; and if the plants are not allowed to suffer for want of water, and are thinned out in time, they will be less liable to "bolt." I believe where Henderson's Pine-apple Beet can be obtained, as true and genuine as when it was first sent out, that there is no better table Beet to be had. Sow a few seeds of the various kinds of Broccoli, Kales, and other Winter Greens. It is best to divide the seeds into three portions, and make three sowings at intervals of a fortnight or three weeks, sowing the last in April; for, after that month, it is very little use sowing seeds, the produce of which require a long period of growth if they are to attain anything approaching their full development. It is always best, before the men leave the place to place nets over all seeds liable to be attacked by birds at the time of sowing. Thus no risk is run, and time is saved.—E. HOBDAV.

March in a Paris Market Garden.

Place in position frames intended for Melons, French Beans, and Tomatoes. Do the same with regard to cloches. Trench ground for Celery, Melons, Tomatoes, Cucumbers, and French Beans. Carry out manure to form hot-beds for these plants. If the manure is dry, spread it out and water it some days before it is used, or else make it into ridges. Continue to surface-dress the beds with spent manure, and clear out old trenches. Sowings.—March is the month for sowing in hot-beds and in warm sheltered parts of the garden. Pink and red Radishes, Carrots, Leeks, Scallions, Spinach, Asparagus, and Orach, may now be sown. In warm beds sow Egg-plant, Basil, Borage, American Spinach (*Basella*), white Celery, Rouen Chicory, Flageolet French Beans, Melons, Capsicum, and Potatoes. In cold beds under frames sow garden Beans and French Beans. In old hot-beds sow French Beans and white Mustard. In the open ground set Strawberries, and sow Fennel, Chervil, Cabbages, Brussels Sprouts, Cauliflowers, Broccoli, Seakale, Turnips, Onions, Sorrel, Pimpernel, Dandelion, Leeks, Peas, Purslain, Salsafy, Scorzenera, Savory, New Zealand Spinach, Tomatoes, and Thyme. Plant off-sets of Artichokes and cuttings of Sorrel (*Oxalis*). Plantings, Transplantings, and Interplantings.—Transplant into nursery-beds all the plants sown last month, such as Melons, Cucumbers, Egg-plants, and others. Plant out white Roman Lettuces, and grey and red-seeded Cabbage Lettuces in the open ground, and Rouen Chicory, Melons, Cucumbers, and French Beans in hot-beds. Interplant Cauliflowers in hot-beds. Plant out Garlic, Shallots, and Leeks sown in hot-beds; Chives, Asparagus,

Tarragon, and Potatoes in a sheltered place. Multiply the Chinese Yam by means of its bulbils. *Treatment of the growing plants.*—Hot-beds and forced crops require the same care as during the preceding month, *i.e.*, if the season continues to be severe. Open-air hot-beds should be covered with mats. When the sun is too warm, all the young plants should be covered from eleven to two o'clock for some days. Water them sparingly. Regular watering commences at the end of the month if it is warm and dry, but the frames should be watered whenever they want it. Crops gathered will be the same as in last month, with the addition of Purslain and early Potatoes. *Special Remarks.*—The open-air hot-beds may be devoted to Cucumbers, and frames may be exchanged for cloches, or *vice versa*. Cabbage Lettuces may be replaced by Melons, Tomatoes by French Beans, Melons by Onions, Cabbages, Corn-salad, Rampion, or Chives.

KEW IN SIR JOSEPH BANKS'S TIME.

PROFESSOR OWEN'S letter in your last number, though ostensibly on the subject of the permanence of varieties, seems rather to have the object of throwing a stone at Kew. His reference to the "prime intention of the wise administrator, Sir Joseph Banks, through whose suggestions and recommendations these botanical gardens were founded and developed," tempts me to quote a passage from a work by the late Dean Herbert,* well known as one of the most skilful, learned, and scientific cultivators of plants who ever lived, to show how far Professor Owen's idea of the way in which things were done at Kew under Sir Joseph Banks corresponds with the opinions of scientific men at that time. Dean Herbert, whose investigations on the hybridisation of plants, are too little known at present, would, I should imagine, have been the last to write so severe a criticism as the following, if any experiments were being made at Kew; but he says, on page 247:—"The illiberal system established at Kew Gardens by Sir Joseph Banks, whereby the rare plants collected there were hoarded with the most niggard jealousy, and kept as much as possible out of the sight of any inquirer, led, in the first instance, to a feeling of satisfaction whenever it was known that the garden had been plundered, and some of its hidden treasures brought into circulation; and the indifference with which such thefts were regarded, if they were not actually winked at, by cultivators, led to such great laxity of conduct that, until the practice was stopped by a prosecution, every private collection became exposed to the like depredations, and the falsehoods that were told to cover the thefts occasioned a great deal of confusion concerning the native habitation of plants introduced at that period. It was the narrow-minded doctrine of Sir Joseph Banks that he could only render the king's collection superior to others by monopolising its contents, and by so doing he rendered it hateful and contemptible, whereas, if he had freely given and freely received, and made its contents easily accessible to those who were interested in them, it would have been a pleasure and a pride to the nation. It is now near twenty years since I visited that odious and useless establishment. Formerly I went there often, but always in vain, for if I enquired for any rare plants, which I had reason to believe were in the collection, excepting those which from their size could not be concealed, my conductor always denied any knowledge of them; and if I asked to speak to a person better acquainted with the plants, I was told I could obtain no further information. The multitude of rare plants that have flourished and perished there unobserved, I believe to be very great. I owe no thanks to that establishment, but for the mere permission to walk straight forward through the houses. I must do Mr. Salisbury the justice to say that he repeatedly remonstrated with Sir Joseph Banks in vain on the subject." What a contrast this is to the management of the gardens at the present time, every one who has had anything to do with them must well know. The authorities, from the Director downwards, both in the herbarium and the gardens, though often overdone with work, are always ready to give any information and advice in their power about plants taken or sent there; and the liberality with which all duplicates of plants, alive or dead, are distributed and exchanged, is well known to hundreds of correspondents in all parts of the world. Though, of course, a private individual like myself has no right to speak on such a matter, I should think it impossible, with the very small staff of skilled gardeners at Kew to carry on such investigations as Professor Owen suggests, which require intelligence of the highest order as well as the most minute and careful attention, to be of any value; and, as to the fact of Lieut. Cameron's collection having gone there instead of to the British Museum, I say, as I think nine out of ten unprejudiced persons would say, that collections in any branch of natural history made by the Government, or by private enterprise, are best placed where they will be most prized and made most useful. I can only express

a feeling—which I am sure will be understood by all who take an interest in, and have had to do with, Kew Gardens—of the deepest gratitude to the authorities and the staff employed there for the universal courtesy and help which I have received on many occasions; and, in conclusion, I would say that, so long as the gardens are carried on as they are now, it is the duty of every lover of plants in this country to send the first duplicate of any new or rare plant he may have, alive or dead, to Kew Gardens.

H. J. ELWES.

Miserden House, Cirencester.

THE FERNS OF NORTH AMERICA.

By JOHN H. REDFIELD.

For many reasons, writers upon the Flora of North America have found it convenient and useful to limit their province to that part of the Continent lying north of Mexico; excluding also the West India Islands. In considering the distribution of the Ferns of North America a similar limitation will be followed, which will exclude a large number of tropical forms that can be better studied in connection with South American or Caribbean geography. As Ferns are for the most part very dependent upon shade and moisture, their distribution over the Continent will be largely determined by the rainfall of the different portions; and the conditions which distribute the forest legions will show us where we may expect to find the largest number of species, and the greatest development in number and luxuriance of individuals. And as many species live only in the crevices of rocks, or root only in rock-loving mosses, they find in the rugged cliffs of mountain sides all the necessary conditions. So, as we might expect, the eastern portion of the Continent—traversed from N. E. to S. W. by the Appalachian range of mountains which receive and condense the moisture of the winds from the Gulf of Mexico and the Atlantic—furnishes the greatest number of species. Near the Gulf the moisture of the atmosphere is accompanied by sufficient heat to permit the establishment of many species belonging to the Carribean province. These soon disappear as we go northward, and as we proceed into Canada and the British possessions, many of the Alleghanian forms die out, and are succeeded by more hardy and cold-enduring species. A few of these continue into high arctic latitudes. Passing now westward, beyond the Alleghanian slopes, into the flat, treeless prairies of the Mississippi Valley; and still farther, into the arid plains which extend to the foot of the Rocky Mountains; we have a vast region, in which the species gradually diminish in number, and finally almost entirely disappear. Even in the Rocky Mountains we find many of the needed conditions wanting. An atmosphere almost devoid of moisture through much of the year, and so free from cloud as to give burning effect to the direct rays of the sun, limits the Fern growth to deep rock clefts and to the valleys of snow-fed streams. A few Boreal and Siberian forms have crept downwards from the north, meeting some of the drought-resisting species which have made their way from Mexico. Beyond the Rocky Mountains we enter a wide-spread desert, utterly incompatible with Fern life, though the island-like snow-covered mountain ridges, which here and there emerge from the vast expanse of the thirsty plains, occasionally give shelter to a few hardy species. As we approach the western borders of the Continent, the noble Coniferous forests of the Cascade Mountains and of the Sierra Nevada again offer inviting conditions, and accordingly we have here a larger proportions of Ferns than we have seen since leaving the Appalachian regions. In California the dry plains, which lie between the Sierras and the coast range, again interrupt the Fern life, which, however, re-appears upon the coast range. As we go northward along this western coast, the rains become more abundant and the Ferns more luxuriant; but, as we go towards Southern California, aridity again prevails, restricting the number of species and individuals, and modifying their types. Abundant as is the Fern-growth of Alaska, Washington, and Oregon, the number of species is much less than upon the Eastern border of the Continent. A few species are peculiar, while the remainder are Asiatic forms which seem to have made their way across the Straits or over the Aleutian Isles even as far south as California, there meeting a few types which have their homes in the Andes.

The number of species which inhabit North America, as here defined, is about 125. They may be arranged in six geographical divisions, *viz.*:—1. Cosmopolitan; 2. Boreal; 3. Appalachian; 4. Pacific; 5. New Mexico or Central; 6. Tropical.

I. Cosmopolitan.—Widely distributed over the globe, in both temperate and tropical regions.

Pteris aquilina.

Asplenium Trichomanes.

The first of these, thriving in sandy barrens, occurs abundantly in both the Old and New World and in the islands; from Lapland in the north to New Zealand and Tasmania in the south. In North America it extends from Labrador and Alaska southward to the

* Herbert's "Amaryllidaceæ, or, Treatise on Bulbous Plants." London, 1837.

isthmus, avoiding only the arid and alkaline plains of our western interior. The other species of this group thrives only in the crevices of shaded rocks, and this condition alone seems to limit its distribution. Throughout the globe it is represented almost as universally as the *Pteris*. There are a few others of the species which are so widespread as almost to claim a place in this division, but which it will be more convenient to consider in the other groups.

II. Boreal.—Inhabiting (with a few exceptions) the northern portion of the United States, extending through Canada and British America, some species even reaching Labrador, Greenland, and Alaska, and nearly all represented also in the northern portions of the Old World.

<i>Phegopteris polypodioides</i> ,	<i>Cryptogramma crispa</i> ,
" <i>dryopteris</i> ,	<i>Cheilanthes argentea</i> ,
" <i>alpestre</i> ,	<i>Cystopteris fragilis</i> ,
<i>Struthiopteris germanica</i> ,	" <i>montana</i> ,
<i>Aspidium Lonchitis</i> ,	<i>Woodsia hyperborea</i> ,
" <i>aculeatum</i> ,	" <i>glabella</i> ,
" <i>fili-mas</i> ,	" <i>ilvensis</i> ,
" <i>fragrans</i> ,	" <i>oregona</i> ,
" <i>spinulosum</i> ,	<i>Botrychium Lunaria</i> ,
<i>Scolopendrium vulgare</i> ,	" <i>matricariaefolium</i> ,
<i>Asplenium viride</i> ,	" <i>lanceolatum</i> ,
" <i>septentrionale</i> ,	" <i>simplex</i> ,
<i>Pellaea gracilis</i> ,	" <i>boreale</i> .
<i>Lomaria spicant</i> ,	

Of the species here grouped we note that *Phegopteris alpestre* has only been observed in North America upon the western coast—coming down as far as California, according to Mr. Baker—and upon the coast of Greenland. *Aspidium filix-mas*, so abundant in the Old World, is very restricted upon this Continent. It is occasionally found in Canada and near Lake Superior, and occurs rarely in the Rocky Mountains. *Aspidium aculeatum*—so wide-spread in some of its forms—is local upon our Continent, and has not been seen below about 42°. *Scolopendrium*, so abundant in Great Britain, is still more restricted here, and seems confined to a few rocky glens which open into the ancient basin of the great lakes. *Asplenium septentrionale*, widely distributed in the mountains and colder portions of Europe and Asia has, on our Continent, been seen only in the Rocky Mountains, where it reaches as far south as latitude 32°. *Asplenium viride* does not penetrate the United States, nor is *Woodsia hyperborea* represented with us, unless *W. glabella* be viewed as a variety of it. *Woodsia oregona* might perhaps be ranked with the Pacific or Rocky Mountain species; but, as it has been noticed as far eastward as Lake Superior, it may claim place with the boreal species, though restricted to the New World, so far as known. *Cystopteris montana*, a high northern species of the Old World, has been seen in Alaska; also far north in the Rocky Mountains, and on the north of Lake Superior, and in Labrador; while *C. fragilis* is so widespread on the globe as almost to deserve a place in our first division, and, were it not for its northern proclivities, might be called an Appalachian species. *Pellaea gracilis* would be an exclusively American form but for the fact that it occurs in the Himalaya Mountains, where several others of our American species also appear. *Lomaria spicant*, common in the northern regions of the Old World, appears only on our western border. *Botrychium Lunaria*, frequent throughout northern Europe, and not rare in British America, barely enters our own boundaries; but the other *Botrychia* of this group have nearly all been occasionally found within our limits, and are, perhaps, more abundant than is supposed, their small size and isolated habit enabling them to elude detection. *Cheilanthes argentea* is a Siberian species which reaches the Aleutian Islands, and perhaps Alaska.

III. Appalachian.—Extending throughout the mountain and hilly regions of the States east of the Mississippi, often to the coast, and northward into Canada, and in a few instances also inhabiting the Old World.

<i>Polygodium vulgare</i> ,	<i>Aspidium cristatum</i> ,
<i>Phegopteris hexagonoptera</i> ,	" <i>Goldieanum</i> .
<i>Onoclea sensibilis</i> ,	" <i>marginale</i> ,
<i>Cheilanthes vestita</i> ,	" <i>acrostichoides</i> ,
" <i>tomentosa</i> ,	<i>Cystopteris bulbifera</i> ,
<i>Pellaea atro-purpurea</i> ,	<i>Woodsia obtusa</i> ,
<i>Adiantum pedatum</i> ,	<i>Lygodium palmatum</i> ,
<i>Camptosorus rhizophyllus</i> ,	<i>Osmunda regalis</i> ,
<i>Asplenium filix-femina</i> ,	" <i>Claytoniana</i> ,
" <i>thelypteroides</i> ,	" <i>cinnamomea</i> ,
" <i>angustifolium</i> ,	<i>Botrychium virginicum</i> ,
" <i>ebeneum</i> ,	" <i>ternatum</i> ,
" <i>ruta-muraria</i> ,	<i>Ophioglossum vulgatum</i> ,
" <i>pinnatifidum</i> ,	
" <i>montanum</i> ,	<i>Asplenium marinum</i> ,
" <i>Bradleyi</i> ,	<i>Woodwardia virginica</i>
<i>Dicksonia punctilobula</i> ,	" <i>areolata</i> ,
<i>Aspidium Thelypteris</i> ,	<i>Schizaea pusilla</i> .
" <i>Noveboracense</i> ,	

Of the species in this division we remark that *Onoclea sensibilis*, though absent from Europe and most of Asia, appears in Manchuria and Japan. I am not aware that it now occurs in the western portion of our own Continent, but it is a very interesting fact that it has been discovered in a fossil state in the eocene tertiary on the eastern border of Montana. *Cheilanthes vestita* is hardly found north of 41° extending south-westerly along the mountainous region to about 34°. *C. tomentosa* seems to prevail along the western slopes of the mountains, and reappears in the mountains of Arkansas and in the Rocky Mountains. *Pellaea atropurpurea* stretches to the north-west even to Slave Lake, and south-west to the Ozark Mountains, and occurs sparingly in the Rocky Mountains. Our lovely *Adiantum pedatum* is wanting in Europe, but appears in the Himalayas, in Manchuria and Japan; again in Alaska, thence along our western coast as far as California. *Camptosorus rhizophyllus* is limited to this district, but an allied species without auricles, occurs rarely in Siberia. *Asplenium filix-femina* is almost a cosmopolite, but its fellow in the section *Athyrium* (*A. thelypteroides*) occurs elsewhere only in Asia. *Asplenium ebeneum* is rather tropical in its relations, and extends into tropical America as far as Peru, and appears in the Old World only in South Africa. Yet with us it extends north to about 45°. *Asplenium montanum* is appropriately named, and is strictly Appalachian. It has been observed as far north as Ulster Co., N. Y., extending thence south-westerly to Alabama. *Asplenium pinnatifidum* is rare and local, and has been reported, so far as we know, only from Pennsylvania, North Carolina, Southern Illinois, Missouri, and Arkansas. It has been erroneously considered by some as a variety of *Camptosorus rhizophyllus*, but not only do the generic distinctions hold which Hooker indicated, but its habit is entirely different. Instead of running freely over the surface of rocks, rooting in the Moss which covers them, it grows deep in the retreating crevices of precipitous cliffs, rooting itself most tenaciously to the rock, and is rarely or never proliferous. *Asplenium Bradleyi* has, as yet, been seen only in East Tennessee and Kentucky. *Aspidium thelypteris* is widespread in the northern hemisphere, and less so in the southern, but its very near relative *A. noveboracense* is strictly Appalachian. So also are the rest of the *Aspidia* of this division, except *A. cristatum*, which also appears in Europe. *Lygodium* is, for the most part, a tropical genus, and most of its species are widespread in warm regions. Our own beautiful species, however, is strictly confined to this division, and occurs but rarely in it; usually in wet sandy alluvium. Of the three *Osmundæ*, *O. regalis* is almost cosmopolitan. *O. cinnamomea* extends from far north into the tropical regions of South America, and, though wanting in Europe, it reappears in Eastern Asia; while *O. Claytoniana* is another species common only in the Appalachian and the Himalayan region. All three are wanting west of the Rocky Mountains. Both of the *Botrychia* of this group are occasionally found in the northern hemisphere of the Old World. The last four species of this group are rather maritime than Appalachian. *Asplenium marinum* is strictly a littoral species, but it is somewhat doubtful whether it is entitled to a place in our catalogue. It is said to have been collected upon the coast of Newfoundland by Kendal more than thirty years ago, but later collectors have not confirmed it. *Woodwardia areolata* is limited to the marshes of the seaboard states, from Cape Cod southward. *Woodwardia virginica* has about the same range, but also appears in the regions bordering on the St. Lawrence and the great lakes. Our little *Schizaea* is known only in the Cedar swamps of New Jersey, at three or four points over a limit of about thirty miles, although it is said to have been collected in Newfoundland many years ago. Perhaps thorough search in appropriate localities may yet prove its range wider than we know.

IV. Pacific.—Extending along the western border of the Continent at points from Alaska to California; in a few cases appearing also in the Rocky mountain region.

<i>Polypodium falcatum</i> ,	<i>Pellaea andromedæfolia</i> ,
" <i>intermedium</i> ,	" <i>Bridgesii</i> ,
" <i>californicum</i> ,	" <i>densa</i> ,
" <i>Scouleri</i> ,	" <i>ornithopus</i> ,
<i>Gymnogramma triangularis</i> ,	<i>Aspidium munitum</i> ,
<i>Notholaena Newberryi</i> ,	" <i>californicum</i> ,
<i>Cheilanthes californica</i> ,	" <i>argutum</i> ,
" <i>gracillima</i> ,	<i>Woodsia scopulina</i> .
<i>Pellaea Breweri</i> ,	

One or two additional species occur in California, which will be more appropriately considered in the next group. *Gymnogramma triangularis* extends from Vancouver's Island to Southern California and reappears in Ecuador, South America. *Notholaena Newberryi* is only known at present in Southern California. *Cheilanthes gracillima* has been noted from latitude 44° to 35°. Mrs. Lyell must be wrong in ascribing it to Missouri. *Woodsia scopulina* has been seen from latitude 49° to Columbia River, and appears also in the

Rocky Mountains as far south as latitude 39°. We as yet know too little of the range of most of these species to assign a precise limit.

V. New Mexican.—Inhabiting the central mountain regions of New Mexico and Colorado; many of the species extending thence into Mexico and some even to South America, and a few of them also occurring in California.

<i>Gymnogramma pedata</i> ,	<i>Cheilanthes lanuginosa</i> ,
<i>Notholæna sinuata</i> ,	" <i>Wrightii</i> ,
" <i>ferruginea</i> ,	" <i>microphylla</i> ,
" <i>candida</i> ,	<i>Pellæa pulchella</i> ,
" <i>cretacea</i> ,	" <i>flexuosa</i> ,
" <i>dealbata</i> ,	" <i>Wrightiana</i> ,
" <i>Fendleri</i> ,	<i>Adiantum chilense</i> ,
<i>Cheilanthes aspera</i> ,	<i>Woodwardia radicans</i> ,
" <i>Fendleri</i> ,	<i>Aspidium juglandifolium</i>
" <i>Lindheimeri</i>	<i>Anemia mexicana</i> .
" <i>Eatoni</i> ,	

The prevalence of the drought-resisting genera *Notholæna*, *Cheilanthes*, and *Pellæa* in this list will be at once noticed. The precise range of many of these we have yet to learn. *Gymnogramma pedata*, *Notholæna ferruginea*, *N. candida*, *N. cretacea*, *Cheilanthes microphylla*, are all known to extend into Mexico and Central America. *Adiantum chilense* and *Woodwardia radicans* also occur in California; but their relations are rather with this group, and the latter species is the only one of the group which also appears in the Old World.

VI. Tropical.—Inhabiting the border of the Gulf of Mexico, most of the species extending into the West Indies and Tropical America:

<i>Acrostichum aureum</i> ,	<i>Asplenium dentatum</i> ,
<i>Vittaria lineata</i> ,	" <i>myriophyllum</i> ,
<i>Polypodium Plumula</i> ,	<i>Aspidium patens</i> ,
" <i>incanum</i> ,	" <i>ludovicianum</i> ,
" <i>aureum</i> ,	" <i>unitum</i> ,
" <i>phyllitidis</i> ,	<i>Nephrolepis exaltata</i> ,
<i>Cheilanthes alabamensis</i> ,	<i>Trichomanes Petersii</i> ,
<i>Pteris cretica</i> ,	" <i>radicans</i> ,
" <i>longifolia</i> ,	<i>Anemia adiantifolia</i> ,
<i>Adiantum Capillus-veneris</i> ,	<i>Ophioglossum bulbosum</i> ,
<i>Blechnum serrulatum</i> ,	" <i>nudicaule</i> .

Of the above, we note that *Trichomanes Petersii* is quite local, having been seen only in Alabama and Florida. *Cheilanthes alabamensis* reaches through Texas into New Mexico. *Polypodium incanum* extends farther north than any other in the group, reaching Virginia, on the sea-board, and extending up the Mississippi Valley into Illinois, but avoiding the colder mountainous region between. *Adiantum Capillus veneris* reaches North Carolina on the east of the mountains and Missouri on the west. It also reappears in Utah and Arizona. This species is almost cosmopolitan and reaches high latitudes in the Old World, but with us is limited as above. The two species of *Pteris* of this group also extend around the globe except in high latitudes. Of the 125 species here enumerated sixty-nine, or about 55 per cent., are found in the New World only, and of these sixty-nine about fifty-three, or over 42 per cent. of the whole, are restricted to the limits we have defined, except that a few of them extend more or less into Mexico. We have, then, seventy-two species left, which we share with other portions of the world—some of which are represented in more than one other region. A brief glance at the numerical relationship of these is all that we have space for. We have forty species in common with Europe, of which four are not found elsewhere. We have thirty species in common with the Himalaya, or northern India, of which two are not found elsewhere. We have, in common with northern or eastern Asia, thirty species, of which two are not found elsewhere. If we make a similar comparison with the Himalayan region and the north and east of Asia united, we have forty-six species in common, of which five are exclusive. If we add Europe to this comparison, we have fifty-two species in common, of which twenty-six are exclusive. We have also twenty-nine species which occur in the West Indies, twenty-six which occur in Africa or southern Asia, thirty-six which inhabit South America, and nineteen which occur in Polynesia. The preponderance of Asiatic forms in our Fern flora will at once be perceived, and opens an interesting field of inquiry. Those wishing to enter upon it are referred to Dr. Gray's "Observations on the Relation of the Japanese Flora to that of North America, and of other parts of the Northern Temperate Zone;" in the sixth volume of "Memoirs of Am. Acad. Arts and Sci.," second series; also in "Silliman's Journal," Sept., 1859. And in this connection the student will find the elaborate and excellent tables in Mrs. Lyell's "Geographical Hand-book of Ferns" of great service. Seldom has been brought together such a mass of botanico-geographical facts, so well systematised, and so convenient for use.—"Torrey Botanical Club Bulletin."

THE KITCHEN GARDEN.

THE READING POTATO TRIALS.

THE Potato crop is so valuable, that any facts throwing light upon the causes of success or failure will be of more than ordinary interest; allow me, therefore, to give you the result of some trials made at Reading with 350 different kinds of Potatoes last year. They were all grown side by side, under precisely the same conditions; a capital opportunity is therefore thus afforded of testing how far a change of seed, so much recommended, is worthy of attention. In one case there were eleven distinct samples of one variety, each sample planted having been grown the year before on a different kind of soil, in various parts of the country, expressly for seed purposes. The first lot was grown in the same field the previous year in which the trials were made last season, thus effecting no change. The next was from a distance, off poor soil, and, though planted alongside No. 1, and grown on exactly the same extent of ground, No. 2 produced quite double the crop of No. 1. No. 3 was from a very heavy loam in the west of Berkshire, and it came out much inferior to No. 4, which was grown in Essex on poor light land, almost without manure. No. 5 from Oxfordshire, and No. 6 off fen-land country, both evidently found a suitable change in the light loam about Reading. Nos. 7 and 8 were off rich land, and the yield was small, but nothing approaching the wretched crop produced by No. 9, which was grown within a few yards of the same spot last season. No. 10, again, which came from a distance, was good; but No. 11, which, curiously enough, was grown within a quarter of a mile of the trial ground was the best of all; on inquiry, however, I learned that it was off quite a different soil, thus fully bearing out the soundness of the view that a change of seed is necessary. Messrs. Sutton, in fact, informed me that the simple change from any of these different districts to their trial ground was valuable. Yet by far the largest of the crops were from those samples which represented Potatoes grown on very poor, and especially fen, land. The change from black peaty soil to the light loam of the trial plot was evidently most suitable. Apart from the question of change of seed, it was most interesting to note the various characteristics, and relative merits, of the different varieties. Here were Victorias, Queens, York Regents, Patterson's Regents, Walker's Regents, Dunbar Regents, Dalmahoy's, Gryffe Castle, Rocks, Wellingtons, Shaws, Oxford's, Fortyfolds, Drummond's Prolific, Flukes, Lapstones, Skerry Blue, and a score more, all giving very different results, both in quality and quantity of produce. One or two varieties particularly struck me as being evidently larger croppers, of finer quality, and freer from disease than the rest. Of Americans, I should recommend Snowflake, Willard, Early and Late Rose, and Climax, as being the best for general cultivation, while King of the Earlies is peculiarly suitable for forcing. Amongst English varieties, the sorts most reliable for early use appear to be a new selection of Ashleaf, called Sutton's Ashleaf Kidney, Early Hammer-smith, a fine prolific Kidney, which has taken many prizes, and early Giant King, a round Potato of fine quality. For late use, Sutton's New White Fluke is certainly one of the best. Oxfordshire kidney is a fine Potato, while last, but not least in importance, comes Red-skinned Flour-ball and Hundredfold Fluke. The Red-skin Flour-ball is a large, round pink, rough-skinned variety, with a white flesh, shallow eyes, and possessing the remarkable recommendation of producing none but large tubers, all fit for the table. From eight to twenty Potatoes are often turned up from under each root; and, as they grow immediately below the haulm all together, one toss of the fork brings them to the top. This being such a robust-growing variety, seemed to be better able to dispense with the necessity for change of seed than older sorts; still, there was a marked difference in the quantity of produce from some lots, a circumstance which could only be traceable to the want of such a change. There is one thing about this Potato which should be borne in mind, and that is that it is essentially a late-eating sort, and is not often fit for the table before February; and it should always be steamed, not boiled. The old American Red Seedling, with its numerous deep eyes and yellow flesh, and other sorts, are often substituted for the Red-skinned Flour-ball; care should therefore be taken to get the genuine Flour-ball. The beautiful striped Hundredfold Fluke is another fine Potato, and, as this variety is not only a good keeper, but also as good for table when dug as in the spring, it cannot fail to become a favourite.

ALNWICK.

Seville Long-pod Bean.—This variety of Broad Bean has been for many years in cultivation on the Continent, especially in Spain, where it has done good service in the way of supplying food during the war. It well deserves the high commendations lately bestowed upon it, and ought to be in every good garden. The true

variety, however, is somewhat difficult to obtain, inasmuch as long-podded Beans, in every respect different from it, are often supplied for it; while a Spanish Bean, very similar to it as regards seed, but short-podded, is sold under the name; hence its introduction into English Gardens is but slow. It is, however, the earliest and longest podded Bean in cultivation, and a variety quite distinct from any other. Its pods are tender, and fit for use ten or twelve days before those of the common long-podded sort grown in the south of France. It was stated a few weeks ago in your columns, that the common long-pod Bean was the earliest; that is not, however, the case, for in English gardens, the Seville Bean is from four to six days earlier than that. It grows moderately robust, with one or more slender stems, according to the distance at which the plants stand apart; its leaves are of a bright green colour, and its pods, three to six on each plant, are extremely long, measuring often from 6 to 10 inches in length, and 1 inch broad; they are of a bright fresh green colour, quite pendent, and contain from five to eight fine Beans, which are bright fawn coloured, oboval, flattened, and the largest after the Windsor varieties. They should be sown now, as soon as possible, in a warm, well-protected border, which should be slightly covered with rough litter, in the event of frost. Being only a moderately-heavy cropper, and not so hardy as some other sorts, it is not so well adapted for field culture in England as it is on the Continent; but, as a garden Bean, it is well worth attention.—D. GUIHENEUF.

Mr. Buckmaster on Potato-boiling.—Mr. Buckmaster, the South Kensington professor of the art of cookery, has been lecturing in the provinces to crowded audiences upon the art of Potato-boiling. According to Mr. Buckmaster, Nature has put a very great deal into the Potato, and man does not get enough out of it, precisely because he knows not the first principles of the new South Kensington philosophy. We ought, it seems, to pick our Potatoes all of a size, for a big Potato should stay in the water longer than a small one. We ought to wash each individual tuber, handling it tenderly, and clearing its delicate cuticles of all impurities with a soft-haired scrubbing-brush, but on no account to pierce the tender rind, lest the subtle flavour should escape through the wound. Potatoes thus prepared, and carefully boiled in spring water qualified with a requisite admixture of salt, are, we understand, the typical form of carbonaceous food, and if taken with a due admixture of nitrogenous elements, such as are yielded by cheese, buttermilk, sound bacon, and, best of all, a small allowance of good lean meat, are capable of forming a wholesome and a palatable dietary.

The Early Rose Potato in France.—In France this is the earliest of all known Potatoes, and there, in the southern departments, it is possible to grow two crops in the same season. The best way to prepare the soil for the Early Rose is to spread a thick coating of well-rotted stable manure on the surface in September, and cover it in at once. As early in March as the season will admit of the operation, sow broadcast a mixture of equal parts of unleached ashes, guano, and finely ground plaster, at the rate of 300 to 400 lbs. per acre; then harrow in both directions, and plant. To work the ground well, to replace the ordinary manure from the stable at the time of planting, by assimilable salts and fertilisers, and to be sure to restore to the soil the potash it lacks, in the form of ashes, crude potash, or nitrate of potash—such is the true practice to follow in order to obtain an abundant crop of excellent Early Rose Potatoes.—“Cultivator.”

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Sowing Celery.—Celery sown on a warm spot just now will be early enough for very many places. It is necessary to prick the young plants out when large enough, leaving a space of at least 6 inches between them; this allows them to develop into sturdy little “stuff” by the time the trenches are ready for them. With attention, these will be fit for use in September. Celery stands the winter better if grown with little or no dung. Water and mulch after planting; they will then require little more moisture.—R. P. B.

Two Crops from Forced Seakale.—Seakale, like other members of the family to which it belongs, when cut over, will produce a quantity of young shoots in a short time. If forced Seakale is cut as soon as it is fit for table, a second crop will follow on the same plants directly. The second shoots are not so strong if the first are allowed to grow too much; and, as a matter of course, they will not succeed so quickly. They will also become “spindly” if the temperature be higher than from 50° to 55°; the flavour is better when grown cool.—R. P. B.

Blanching Lettuces.—Can any of your correspondents tell me the best method of blanching Lettuces?—X. [Many kinds of Lettuce, including True Paris Cos and Myatt's Green Cos, are, to a certain extent, self-blanching; the only thing required is to tie round the top of the leaves with a string of matting, an operation which should be done when the Lettuce is quite dry. In summer they take about eight days to blanch. We have been cutting all winter the variety known as Black Seeded Brown Cos. This we simply cover up outside with dry Fern, which both blanches and protects.—R. GILBERT, *Barghley.*]

THE FUTURE OF THE ROYAL HORTICULTURAL SOCIETY.

I SHOULD be greatly obliged if you would help me in a matter which I have much at heart. The Royal Horticultural Society is now divided into two sections with different interests—the local Fellows, who use the South Kensington Gardens as a recreation ground, and the horticultural Fellows, who only care for them as a convenient place for holding shows and meetings. It appears likely that the two sections will more or less amicably separate, that the local people will bear the cost of the gardens, and that the horticulturists will have what funds they can collect to spend on horticulture, properly so called. A long experience on the Council has satisfied me that the Society would be much stronger, and more influential with a very large number of Fellows all over the country, at a guinea subscription, than with a limited number of Fellows at a high subscription. Some very influential people would cordially back this plan, but doubt whether enough guinea Fellows would co-operate. I am most anxious to have a practical fact for them. While talking over the question at the show on Wednesday, one of the great nurserymen (Mr. Standish) said, “I know something of Manchester, where I am doing some large work, and I think many would join there.” It then struck me that Manchester would be an excellent test place. At the old Chiswick Garden, where new vegetables and fruit are grown side by side, judged, and names reduced, by some of the best men in the country, and at the Committee meetings at South Kensington, to which all new flowers and fruits are sent from all parts, and most carefully judged and reported on, real horticultural work is done which benefits the whole country. I do not think it is too much to ask a guinea from those who care for a garden, and who would like to keep the old Society in an efficient state. I have enclosed a paper, and should be very much obliged if you would sound your friends and see how many names could be collected in the next fortnight. I enclose a pamphlet to show that it is no new idea. GEORGE WILSON.

Heatherbank, Weybridge.

[The following is the “paper” above alluded to:—

“Should the Royal Horticultural Society admit to fellowship at a guinea annual subscription, giving for this a transferable ticket of admission to all the Society's shows at South Kensington and elsewhere, and every day to Chiswick Garden, we, the undersigned, would be willing to become Fellows on this footing.”

(Name)

(Address.)

Guinea Fellowships seem to us to be a good suggestion, and we shall be happy to receive the names of such as are willing to join the Society on this footing at our office, 37, Southampton Street, Covent Garden, London.—ED.]

Poisoning by Monkshood.—Your illustration and article in THE GARDEN on this plant recalls to my mind a circumstance that happened in this neighbourhood last summer, which goes far to prove that it is a very dangerous plant to grow near fences over which cattle can reach. It is a plant of a very striking appearance, and, when in flower, is very ornamental, and for this reason it is rather common in cottage gardens in some places, whilst the fact of its being a deadly poison is known to but few. Last summer a valuable horse had a narrow escape from death from nibbling a few flowers just inside a cottage garden, where his owner had left him tied to the fence a minute or two, whilst he made a call. Fortunately he had only eaten a small portion, and a skilful veterinary surgeon was at hand, who, although he did not know the plant, saw from the symptoms that the horse had taken a virulent vegetable poison, and, therefore, knowing what course to take, the result was not fatal; but I have no doubt this plant has been the cause of a good deal of mischief in this way, without its agency being traced so clearly as in this case.—E. HOBDAV.

National Fruit Culture.—As a matter of increasing national concern, which affects not one class only, but all classes, the Vegetarian Society has been directing attention to the importance of national fruit culture. Nothing but good, we should think, can come of its doing so. The question of food supply of great Britain has not received that attention which its importance warrants. Large areas of land are devoted to a purpose which affords the lowest yield in food produce of any—that of cattle breeding to supply the demands of the butcher. Other extensive tracts of land are occupied with the production of grain for the use of the maltster—an absolute waste, viewed in the light of national economics, against which every intelligent citizen needs to protest. Other large areas are lying untilld to no one's profit. Throughout the kingdom are many thousands of miles of hedgerows and of abutting space along our highways, river-ways, canal-ways, and railways yielding rarely any food product whatever, where continuous lines of fruit trees might be planted. The advantage of shelter, fruit, and beauty are all in favour of this

course. Is it too much to earnestly urge on all the patriotic duty of cultivating the soil of Great Britain so as to afford the maximum yield of food for the daily increasing population which dwells on its surface? Can we do better than direct the attention of all who hold, rent, or till any portion of land, however small, to the costlessness and productiveness—in a word, the patriotic duty of national fruit culture.

A CHAPTER ON TOMATOES.

DURING the past few years much has been said and written concerning the merits of the different varieties of Tomato. In size, flavour, smoothness of skin and solidity of flesh, there has certainly been great improvement made; but among the scores of varieties that have been introduced within the last ten or fifteen years, what have we now that is very much earlier than the old Early Smooth Red? In order to test this matter by actual comparison, a correspondent of "Moore's Rural New Yorker" obtained seeds of eighteen varieties; and to be certain of each kind being genuine, they were purchased either of the originators or of first-rate seedsmen. The seeds were sown in a hotbed April 1st, transplanted into a cold frame when the plants had attained 3 or 4 inches of growth, and again transplanted to the open ground about the 1st of June. Great care was taken to treat them all as nearly alike as possible throughout each season. The table below shows the time of ripening of the first fruits of each kind in 1871, 1872, and 1873. Hathaway's Excelsior possesses more good qualities than any other in the list. It is as early as any, of good size and flavour, and is round and smooth without crease or wrinkle; flesh very solid, and equal to the Trophy in this respect. The Trophy is an excellent kind, but is very liable to rot before getting thoroughly ripe. General Grant and Alger are also good sorts, and have one good quality not possessed by any others—their fruit grows in large bunches and ripens up all at once, early in the season:

	1871.	1872.	1873.	Average.
Hathaway's Excelsior was ripe	July 23	Aug. 13	Aug. 5	Aug. 3
Alger	24	9	15	6
Early Smooth Red	26	12	10	—
General Grant	27	12	12	7
Sims' Cluster	29	19	8	8
Large Smooth Red	25	11	19	3
Keyes' Early Prolific	28	—	19	—
Hubbard's Curled Leaf	—	10	12	—
The Cooks' Favourite	29	15	—	—
Maupay's Superior	27	20	13	10
Arlington	—	—	14	—
Trophy	30	18	15	11
Earley's Defiance	—	12	19	—
Cedar Hill	31	—	—	—
Fegee Red	28	16	20	11
Golden Striped	—	20	14	—
Lester's Perfected	Aug. 5	—	22	—
Tilden	1	—	—	—

Sunken Boilers.—From what has been stated by Messrs. Williams and Hobday, it is evident that the practice of setting boilers below their work is one maintained more from custom than necessity. It doubtless arises from a belief that, as the heated water in the boiler expands, it can only circulate rapidly if the whole of the flow-pipes be above the boiler-level, whereas it is evident that if the heated water be carried from the boiler immediately to a certain height it will flow freely through all parts of the heating apparatus; thus the water would rise to the highest point of expansion, and flow all through the remainder of the pipes by means of gravitation. If a good flow was produced by expansion, an equally rapid circulation elsewhere must result, as the return water would enter the boiler as fast as it passed out at the top, and thus a constant and equable flow would be maintained. Nothing can be more simple than the plan described by Mr. Williams, viz., a syphon pipe fixed a few feet above the top of the boiler with an expansion pipe inserted into the syphon. What works well in his case will work equally well anywhere else. And with this experience on record, sunken boilers may be pronounced useless.—A. D.

New Groves of Giant Trees.—It has been supposed that the Sierra Sequoias, or big trees of California, are confined to a few small and isolated groves. It was discovered last summer that a body of big-tree timber in Fresno county is not properly a grove, but a forest, extending for not less than seventy miles in a north-west and south-eastward direction, with a width in some places of ten miles, and interrupted only by the deep canons which cut across the general course of the forest. Different persons have traced the forest from the basin of the Tule river, in latitude 36° 20', across those of the Kaweah and King's, to that of San Joaquin. The elevation has not been carefully measured, but is supposed to vary from 4,000 to 6,000 feet. Unlike the groves further north, this forest consists mainly, and in some places almost exclusively, of the big tress, and there are also a multitude in all the ages of growth—some just sprouting, and

others saplings only 2 or 3 feet through. The largest standing tree as yet measured is 40 feet in diameter; a charred stump—the tree itself having disappeared—measures 41 feet across. A tree 24 feet in diameter, 4 feet above the ground, is precisely the same thickness 60 feet higher. A fallen trunk is hollow throughout its length, and the hole is large enough to drive a horse and buggy 72 feet in it as in a tunnel. The wood is similar in general character to the Coast Sequoia, or common Redwood, straight in grain, slitting freely, even enough in grain for furniture, and far superior to Oak in its keeping qualities in positions exposed to alternations of moisture. The Sierra Sequoia does not throw up sprouts from its stump as does the Redwood, and can, therefore, be felled out more readily. It was wise in Congress to make a reservation for pleasure purposes of the Mariposa Grove, which is near Yosemite, small and conveniently accessible to tourists by the present routes of travel; but the Tulare-Fresno forest—it is all in those two counties—cannot be converted into a public reservation. Numerous saw-mills will be built on its line, and flumes will carry the lumber down to the consumers.—"San Francisco Alta."

Jones' Method of Drying Fruit.—This was spoken of as having been exhibited in operation at the Cincinnati Exposition during the past autumn, and attracted much attention. It is the invention of Jones Brothers, of Centreville, Mich. One of these establishments is in operation at Grand Rapids, Mich., as well as one on the Alden principle, which is owned by the same proprietors, who say that the Jones plan is in some respects superior to the other, but being new it requires some little improvement, and they defer giving a decided preference until after further trial. It differs from the Alden method in having the heated chamber in a horizontal position, the fruit being placed on revolving racks, and the work of putting in and taking out all done on one floor, thus avoiding the necessity of a three-story building, and the journey up and down stairs required for the Alden method. But, on the other hand, the Jones apparatus requires a small steam engine, or other power, to drive the fan which keeps the heated air in motion, and causes rapid evaporation. In large establishments the steam power is also used for driving the paring and slicing machines, and for making Apple jelly out of the cores and seeds.—"Cultivator."

The late Mr. Buckley.—We are glad to find that Messrs. Rollisson have taken up the cause of the late Mr. Buckley's family, who have been left almost destitute, and have organised a committee to obtain subscriptions on their behalf. Let us, therefore, hope that their efforts may meet with that encouragement which they deserve. Contributions may, in the meantime, be sent to Messrs. Rollisson & Sons, Upper Tooting.

NOTES AND QUESTIONS—VARIOUS.

[Many notes and answers, obligingly sent us by correspondents, are unavoidably omitted this week from want of room.]

Water Convolvulus.—Can any of your readers tell me to what plant this name refers?—INTERNATIONAL.

Sowing Scotch Fir Seeds.—Your correspondent "Hortus" (see p. 102) may sow his Scotch Fir seeds on well pulverised ground early in April, covering them with $\frac{1}{2}$ inch of fine soil. Should drought set in cover with mats or litter, rather than water, until the seeds are up.—J. BELL, *Strathfieldsaye*.

Early Louise Peach.—Allow me to supplement Mr. Lumsden's note (see p. 170) by recommending Early Louise as the best early Peach with which I am acquainted; and it is equally well adapted for outdoor growth or for forcing. I gathered a fine dish of it on the 28th July, last year, from a tree growing on a west wall.—W. WILDSMITH, *Heckfield*.

Amies' Chemical Manures.—This has been tried extensively at Chiswick during the past season, and with satisfactory results. It may be used with perfect safety even in the case of the most delicate kinds of plants, either as a top-dressing or mixed with the soil, while such plants as Fuchsias and Pelargoniums are greatly benefited by its application. It has also been used for Potatoes in the open ground with the best results.

Out-door Grapes in Scotland.—"J. S. W.'s" remarks on Grape growing in the open air, induces me to say that I, too, have seen Grapes growing in the open air in the south-western district of Kirkcudbrightshire, and in Renfrewshire. In both places, the Vines were growing on the walls of bakehouses. Those grown in Kirkcudbrightshire were quite equal to some that I have seen imported. But those grown in Renfrewshire were not so good.—WM. LAURIE, *Alva*.

Water-proof Cement for Stokeholes.—In reference to sunken boilers, allow me to say that a dry stokehole, even if the water is 4 feet around the outside of it, may be secured by the use of cement all round and underneath, so as to prevent the water from rising up through the floor. This, to some, may appear to be impracticable, but experience proves that it is not. I have kept water out by means of my cement again and again, and without the uncertainty attending the use of puddle.—JAS. PULHAM, *Broxbourne*.

Gas Boiler for a Conservatory.—Can any of your correspondents tell me what the relative cost is of heating a conservatory by gas and by a slow combustion stove? Say, for example, a boiler and 100 feet of piping are to be kept at any given heat for twenty-four hours, what would the cost be of the coal and coke in the one case and the gas in the other? Of course the gas boiler would lead to a saving in labour, but this need not be calculated in answering the question. What is the best kind of gas boiler for a conservatory?—ECONOMIST.

"This is an art
Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FRUIT-TREE PROTECTION.

THE question as to whether it is desirable or not to afford protection to fruit-tree blossoms may be said to have been settled in the affirmative. From March to May we have sunshine and cloud alternately, frost at night, and heat in the day-time, the latter inducing blossoms to expand, the former ever ready to nip them, even in the bud. The flowering season this year is late, and, so far, favourable; for the later the blossoms, the greater the probability of a crop. Still, we are yet in the midst of danger; for, let but a few bright genial days come on the heels of the cold weather which we have had, and blossoms will open, as if by magic, giving free access to frost. It is imprudent, therefore, to leave Peaches and Nectarines unprotected; and, having determined to save the blossoms, the main questions for consideration are, when and how are we to do this? As to the first, we answer—Now, at the latest. The buds are just on the eve of opening, and, as they open, they need protection, not before. During thirty years' experience, we have never known closed blossoms of stone-fruit to be seriously injured by frost. As regards protection, however, a difficulty arises; semi-opaque or opaque substances—those most impervious to light—are also those least penetrable by cold. Hence the thicker, and, we may add, the rougher a substance is, the more powerfully it protects. But blossoms must have light: shut that out, and we weaken them as well as injure the health of the trees. Hence the most perfect protectors are those which exclude most cold, most effectually prevent the escape of heat, and which cast least shadow on the trees. Glass only, or some semi-transparent substance fulfils these conditions; but glass is expensive, and, unless we are prepared to convert our walls into glass cases for a month or two every spring, some means must be found by which only as much glass as will save the crop, and no more, shall be used. This problem is now in a fair way of being solved; for experience has shown us that glass copings, 18 inches wide, resting on iron brackets immediately under the copings of the walls, are practically frost-proof, or at least sufficiently so to save the blossom-buds from the effects of from 10° to 15° of frost. Of course, the thickness of the glass plays an important part in the matter; and, therefore, rough plate, 28 oz. or 30 oz. to the foot, will be found to be the best, and, perhaps, in the end, the cheapest. The protecting power of this, however, as well as of all copings, is much increased by the blossoms being dry, as it is well known that dry blossoms will resist far more frost than those that are wet. Given, the same trees in the same position and the same amount of frost, one set being wet and the other dry, and the wet ones would have every blossom-bud frozen to death, while the dry ones would escape. Now, protections consisting of thin canvas, frigi domo, and even Russian mats, are not waterproof; but straw mats, so effectually used on the Continent, are so arranged as to keep out rain, and hence, no doubt, to a great extent, their efficiency. As to glass copings, their position is most favourable for protecting the trees from cold. Gardeners have an opinion, very full of meaning, that frost falls in straight lines, or rather, that the radiation of heat proceeds in all directions in straight lines, and that the process continues as long as there is a disparity of heat between any two contiguous bodies. The losing of heat, however, by means of radiation is not absolute, except in one direction, and that is upwards on cloudless nights. The sky absorbs heat so greedily that it takes all from the blossoms and gives none back; hence the danger of injury from frost. But suppose we shut this open door, by means of a wooden coping of sufficient width, the blossoms will retain their heat, and the sky receive none in that direction. Heat, of course, is radiated at right angles to the wall, as well as straight up; but it is also radiated back along these lines from surrounding objects, and the process thus becomes one of reciprocity—not one of taking all and giving back none, as is the case when it is allowed to escape skywards. Check this upward loss, and we save our blossom-buds and secure a

crop. Nature frequently checks it for us by the intervention of clouds, which help in some measure to keep our fruit-buds from perishing. Wooden copings have been advertised, and, doubtless, portable boards are amongst the best of all protectors. They are rain-proof like glass, and they are also proof against radiation, which glass is not, but their shadow proves injurious. They were tried last year in competition with glass, and whilst the latter saved the blossoms, without injuring the trees, the former partially blanched the branches, and even the fruit near the top of the wall. In fact, one of the greatest dangers pertaining to protecting materials is carrying their use to excess. Even glass copings may be applied too soon and kept on too late. We knew a case in which, to save the trouble of applying portable protection, a permanent slate coping, 15 inches wide, was placed on a wall immediately under the ordinary coping. While the trees were young no ill effects were observable, but when they began to cover the wall they also began to get into bad health, and, notwithstanding frequent washings and refreshings from the garden-engine, they missed the dews and the free sweep of the fresh air so much that the slates had to be removed. Therefore, even glass copings should be dispensed with as soon as all danger from frost is over, and, if carefully applied only when the blossoms expand, and stowed away dry when done with, they will last for thirty or forty years. Pyramidal Pears and standard Plums also need protection in some localities; and one of the simplest means of doing this is to suspend straw or Russian mats over them on stout poles. Another mode is to tie a few sprayey branches of shrubs or Firs or Pine trees over and among the branches. Some also wind a few roughly-twisted straw bands loosely round, and among, their trees—a somewhat unsightly plan, but anything is better than the loss of a crop. One of the best means of securing fruit on Pear trees in the form of pyramids or cordons, in average seasons, is to defer pruning them until March. This keeps the blooms abnormally late, and gives them a better chance of setting properly, after the most severe of the spring frosts have passed away. One great advantage of growing cordon Pear, Plum, and other fruit trees, is the facility afforded by their form and size for the most perfect protection. A row of Plum cordons last year had a few boughs of Spruce Fir tied along each, a protection that enabled them to set a capital crop, without further trouble, while every bloom on standard trees close by was cut off by one severe frost, about the middle of May. Plums will bear, swell, and finish remarkably well as ground cordons, 15 or 18 inches from the surface of the soil.

PRESERVED FRUITS AND VEGETABLES.

It is probable that we shall never do much in the way of preserving fruits and vegetables in this country, because our population is so far in excess of our cultivated land that we shall never have either fruits or vegetables to spare for that purpose; our supplies of both must, therefore, be derived from the Continent and the United States. Either fruit or vegetables can be raised far cheaper in America than here at home, because land is there cheaper, and is cultivated in a much more extensive manner, and the produce thus raised, although, perhaps, inferior in point of flavour, is, when preserved, quite as nutritious as that of home growth, and is at any time available for use, while the price is within the means of all. We are glad to see the prejudice against preserved food of various kinds rapidly wearing out, and we see no reason why the choice fruits of tropical climates, such as Bananas, Litchis, Mangoes, Guavas, Kumquats, and many others, should not find their way to our tables in a well-preserved state. We have only to look in the windows of our principal Italian warehouses to see the rapid increase there is just now in the number of preserved fruits and vegetables; and yet it is curious to note how fastidious many are with regard to some preserved fruits, while they eat others almost unconsciously. A good housewife once gave us a look of withering scorn when we mentioned canned Tomatoes; yet all her life, in common with thousands more, she had used dried Grapes (Raisins), Orange-peel, Figs, Prunes, and yearly was one of the most careful of all preservers of home-grown fruit; indeed, her home-made Orange

marmalade, Strawberry jam, Cherries in brandy, and Red Currant jelly, are things we never found excelled in flavour, and yet the prejudice against "new-fangled notions" prevailed. In preserving fruits, cans or tins should never be used if glass or earthenware can be obtained, as the acids decompose the soldering material employed, and the result is the production of highly injurious, if not actually poisonous, salts. Wide-mouthed glass bottles or jars are largely employed in nearly every American household, and are furnished with metallic lids, which screw down perfectly air-tight over an indiarubber washer or ring. Even for the ordinary purposes of jam-making, these ought to find a very large sale in this country, as they are handy and do away with the trouble of oiled papers or bladders, and can at any time be opened, while the state of their contents is always apparent without any unfastening whatever. The beautiful crystallised or candied fruits, now so common in our shop windows, are for the most part of Continental origin. These consist of Plums, especially Prunes and Green Gages, Figs, Pears, Apricots, slices of Pine-apple and Melons, and a few fine Currants. The majority of these are crystallised whole, and are then packed very tastefully in ornamental boxes of various sizes suitable for Christmas, and other presents; and in this form, they sell readily and fetch excellent prices. It has often appeared to me a very singular thing that while during two or three months of the year we have Plums, Cherries, and choice Pears in abundance, and cheap, yet we never adopt any means to preserve them in a form fit for the winter's dessert. Tons of cheap, and, we might add, in many cases, nasty fruit, are sent off yearly from Covent Garden and other metropolitan markets, for jam-making purposes, but so far as the art of fruit-preserving, in its best forms, is concerned, we may be said to know but little, and to practice still less. The Chinese preserve many of their finest fruits, including the Apricot and different forms of the common Orange, all of which form agreeable conserves. The Chinese Kumquat or "Coumquat" is now largely imported, and a large jar of this preserved fruit may now be obtained for a few shillings. A large trade is also done by the Chinese in preserved or candied ginger, which is not a fruit, but the fleshy rhizome of a plant (*Zingiber officinale*) commonly grown in most tropical countries. Apart, however, from the supply sent over from China and the West Indian Islands, in a candied state, large consignments of the fresh roots now arrive annually in this country, and these are sold at prices varying from 1s. to 1s. 6d. per lb. Apart from home-grown produce and the Continental and Chinese productions, however, a very extensive trade has quite recently sprung up in canned goods from the American States. Of the fruits and vegetables sent over in cans the most important are Tomatoes, Cranberries, Peaches, Pears, Pine-apples, Asparagus, and fresh Indian Corn, and in nearly every case these are of good quality, and as nutritious as the newly-gathered productions themselves. The canned Tomatoes I have repeatedly used, and few fruits are more palatable, especially during hot summer weather; but, of course, the canned fruit is not expected to supersede fresh fruit, but merely to be a most excellent substitute for it at a time when it would otherwise be unattainable. Among the newer methods of preserving fruits and vegetables we must not forget the drying or dessicating process, now largely employed in America and elsewhere. The principle in this system consists in evaporating the water from the tissues, leaving the sugar, starch, and other nutritious portions of the fruit in a dry and more portable form, better adapted for use during the winter months or in unproductive seasons. In New York and New Jersey States different modifications of the drying process are being extensively worked, and we have already samples of dried Apples, Pears, and mixed vegetables and herbs for soups, in the market. In some of our country districts Mushrooms are dried for the last-mentioned purpose, and are found to retain their delicate flavour remarkably well; and, where pickled Mushrooms or Catsup is not obtainable, they are a worthy substitute. A new industry has also been opened up in the Western States and California, where the Grape Vine fruits well, for its produce is now utilised for raisins, some of which are sent annually to the English and Continental markets.

B.

NOTES OF THE WEEK.

— MR. MAW informs us that *Crocus minimus* (D. C.), *C. insularis* (Gay), has just flowered at Benthall Hall. It is a lovely little species, roots of which he obtained in April, 1870, in the neighbourhood of Ajaccio.

— IN Mr. Ladd's nursery, at Bexley Heath, there are many houses for forcing Roses, most of which are very large, the latest put up being a fine light house, 300 feet long by 25 feet wide. We have seen many large houses used for forcing Roses in America, where Tea Roses are in great demand in winter and spring; but never anything like this. It now contains what may be described as a meadow of Roses, *Niphetos* in the centre and General Jacqueminot around the side. These are now blooming abundantly, and the half-opened flowers are cut by thousands every evening.

— THE beautiful *Iris reticulata* is now a very conspicuous object in the York Nurseries. It is placed under a south wall, the pots in which it is growing being plunged in ashes, where they have been throughout the winter, and where they have received no artificial protection whatever. Nevertheless, it is now a sheet of blue, and along with it is a variety, with purple flowers, named *Iris reticulata* var. *purpurea*. We have received fresh flowers of this and the ordinary blue kind from Mr. T. Ware; and both are so beautiful, either in pots or as cut flowers, that they deserve to be extensively grown.

— *MASDEVALLIA LINDENI* is now finely in bloom in the Victoria Nurseries, Holloway. It has twenty-five expanded flowers of a brilliant magenta colour, and many others that will open before long. It is one of the finest of the genus, and continues a long time in bloom, which makes it a valuable acquisition. The particular specimen referred to here is the largest in Europe. The beautiful *Tillandsia Lindenii*, bearing splendid cobalt-blue flowers, with a pure white eye, is also blooming at the same place. It has three flower-spikes, from each of which it throws up its beautiful blossoms one after another; as fast as one fades another appears just above it.

— WE are requested by the Royal Horticultural Society to state that, in consequence of the representations made by several of its regular exhibitors (particularly of florists' flowers), the Council have determined to hold all the exhibitions as originally advertised in the schedule for 1875; but that, to carry out the reduction of expenditure, suggested in their advertisement in the gardening papers of the 18th and 20th February last, by striking off the list the exhibitions of the 17th March, 21st April, 1st September, and 10th November, 50 per cent. of all the several prizes offered in the schedule must be deducted, leaving the values of the "medals" as they were.

— ON Wednesday evening last a lecture was delivered in the Council-room of the Royal Horticultural Society, at South Kensington, by the secretary, Mr. W. A. Lindsay, on the "History and Progress of the Royal Horticultural Society." The lecturer graphically alluded to the formation of the Society, and the immense impetus which, in days gone by, it gave to horticulture in this country as well as abroad. Between 1815 and 1823, the Society sent Mr. G. Don to the West Indies as a collector of plants, Mr. Forbes to East Africa, Mr. Parkes to China, and, in 1823, Douglas was sent to North America, and, as is well known, introduced from that quarter many of the most beautiful Conifers now in our gardens. In 1825 it was determined to make meteorological observations at Chiswick, and they have been continued ever since, thus forming one of the most valuable weather-reports on record. Apart from the culture and introduction of new plants, however, the Society published much valuable information in its "Transactions," a publication which alone is said to have cost nearly £40,000. The establishment of horticultural exhibitions at Chiswick, on an extensive scale, contributed much to the Society's popularity at a time when flower shows were comparatively unknown in this country. As a proof that financial difficulties are nothing new to the Society, the lecturer remarked that, when Mr. Sabine resigned and Mr. Benthall succeeded him in the capacity of secretary, the Society owed no less than £20,243—a sum which was cleared off by increasing the subscriptions of the Fellows, and by the fêtes which then proved so successful. In conclusion, the lecturer drew attention to the terms under which the Chiswick Garden was held, and lamented the policy which induced the Fellows to part with so much valuable property, which they had the power of holding, on a perpetually renewable lease, at a mere nominal annual rental. In conclusion, a hope was expressed that the Society would again regain a prosperous position, and that it would in the future continue the good work which it had already done so well in times past.

THE HEMP AS A GARDEN PLANT.

(CANNABIS SATIVUS.)

THIS well-known annual is a native of India and Persia, and is largely cultivated in Europe for the sake of its fibre. In ordinary situations it grows from 4 to 10 feet high, but in Italy, under very favourable circumstances, it sometimes grows as high as 20 feet. In plants growing singly the stem is frequently much branched, but when grown in masses it is generally straight and unbranched. The leaves are long-stalked, and composed of from five to seven long, lance-shaped, sharp-pointed leaflets, radiating from the top of the stalk, and with the margins cut into sharp saw-like teeth. The flowers are of separate sexes on different plants, the males being produced in racemes and generally crowded together towards the top of the plant or ends of the branches, having a five-parted calyx and five stamens; the females are in short spikes, their calyx consisting merely of a single sepal, rolled round the ovary, but open on one side, and they have two hairy stigmas. The fruit (commonly known as "Hemp seed") is a small, greyish-coloured, smooth, shining nut, containing a single oily seed. Hemp was known in Europe in very early times, for Herodotus, writing upwards of 2,000 years ago, mentions it as being cultivated by the Scythians, who used its fibre for making their garments. This plant is useful where the tenderer sub-tropical plants cannot be enjoyed. Single well-grown plants of it look very imposing and distinct, and are good for the backs of borders or mixed groups. For these purposes, it should be sown early in April in the open ground. To get large plants it would, no doubt, be worth while raising it in frames. It loves a warm, sandy loam. Russia and Poland are the two great hemp-producing countries, and it is from them that our supply is mainly derived; but the best product is from Italy. The United States and India likewise send Hemp to this country, but the quality is inferior to the Russian. The harvesting takes place at two periods: the male being pulled up as soon as it has done flowering, and the female not until the seeds are ripe. After pulling, the leaves are struck off with a wooden implement; the stems are then tied in bundles and steeped in water, or water "retted," as it is technically termed (two other processes, dew-retting and snow-retting, are sometimes substituted), the object being to loosen the fibre; they are then spread out to dry and bleach: this is called "grassing," after which the fibre is detached, either by pulling it off by manual labour, or by breaking the stems in a machine, and afterwards scutching them in a similar manner to that employed for the preparation of Flax. The uses of Hemp for the manufacture of cordage, canvas, &c., are too well known to require comment.

The Effect of Transplantation in Averting Damage by Frost.—This has been well illustrated by a case which occurred at Feltham, where a quarter of an acre of ground was sown last spring with scarlet Queen Stock, with the intention that the plants, duly thinned, should remain to flower. The thinnings were planted out during the summer upon the ground close by, and grew into strong plants, though not so large as those that remained in the seed-bed. Over three-fourths of the untransplanted ones are now entirely killed, whilst of those transplanted scarcely one is injured.—"Florist."

THE INDOOR GARDEN.

PROPAGATION AND CULTURE OF THE CARNATION.

THERE are a great many fine varieties of Carnations, and the colours and markings of the flowers of many of them are exquisitely arranged and brought out. In some the blooms are small, in others massive, but all are beautiful and interesting. My first favourite is the old cerise-coloured Clove, the flowers of which are all of one colour, of perfect form, of an agreeable spice scent, and worthy of being grown largely, as it is in many places. Souvenir de la Malmaison is a very common sort, which bears large flesh-coloured flowers, highly fragrant, and useful for house and pot cultivation. Mr. Young, of South Bridge, Edinburgh, has lately raised a seedling

from this variety, which possesses all the good qualities of its parent, but the petals are distinctly striped with deep rose, which places it amongst the Bizarres—a term applied when the flower is striped and of a light and dark colour. Duke of Wellington, Perfection, and many more are of the same class. The blooms of Oscar are nearly yellow, and Queen of Whites is the best white. Scarlets are very plentiful, and are best represented by Boule de Feu, Beauty, Dragon, &c. Most of the named varieties are very good, with their markings well defined and describable, but many of those which a packet of selected seed will produce are equally good and as pretty. Sometimes the progeny surpasses in form and rich markings the variety from which the seed was saved. They are as extensively cultivated in pots for greenhouse and conservatory decoration as they are in beds and borders; but, as the treatment differs somewhat in the two cases, perhaps it will be convenient to consider the two separately.

Indoor Culture.

To have a succession of bloom all the year round, one batch of plants must be prepared throughout the summer to flower in the winter and spring; another batch must be prepared during the winter and spring to bloom in the summer and autumn. Plants which have been flowering throughout the winter will have made sufficient growth to afford a quantity of cuttings at this time, which may be taken off in the usual way, selecting, of course, such shoots as are most likely to form the best and

strongest plants. The lower leaves should be closely cut away with a sharp knife, until a clean stem of two inches is cleared to insert into the rooting material, which should consist of equal proportions of loam, river sand, and leaf mould. Six cuttings may be put round the edge of a 5-inch pot; when put in the centre they do not root so freely, and the pot containing the cuttings must be plunged in a bottom-heat of 70°, and kept there until they are rooted, when they may be potted singly into 3-inch pots, using a mixture in which well-rotted dung is substituted for the leaf soil. They must then be set in a close atmosphere, with a temperature of 50°, until they begin to push into the new soil, when air is gradually admitted until they are fully exposed. I have seen them planted out about the end of April, and grown during the summer in a well-prepared piece of ground until autumn, when they were lifted, and potted into whatever sized pots their growth required. I think, however, they always flower more pro-

Male and Female Hemp Plants.

fusely when grown altogether in pots, and not planted out at all. In pots they need more attention in hot weather to prevent them suffering from drought, but the extra bloom they produce in winter compensates for all this. When grown in pots they should, when necessary, be shifted into larger sizes during the summer, but they should not be potted after the middle of August, or they may not be in that partially pot-bound condition, which is always conducive to flowering about November. Almost any position is suitable for setting them in throughout the summer. When the pots are plunged in coal ashes labour in watering may be saved to a certain extent. That the blooms may open perfectly, the plants should be fully exposed to the light during the winter, and watering with manure-water now and again greatly assists in sustaining the vigour of the plant and blooms. To form a succession to these plants, cuttings prepared in August will root then in a close shaded frame, with no bottom-heat. A 3-inch pot should be used at this time, and one cutting should be put firmly into the centre of it, where it roots freely, and forms a ball, which need not be disturbed when shifting into a 5-inch pot. This size should not be exceeded in autumn, or much care is needed to prevent the soil from becoming sour during the period of short days and long nights. Half the plants should be retained in the 5-inch pots, to flower in the early part of the summer, and the other half can be potted into 7-inch and 8-inch pots to bloom in autumn. Old plants, when they have finished flowering, are sometimes re-potted and kept on for flowering the following season, but these never turn out so well as fresh young plants, and as these can be so easily propagated and grown I always recommend them. Close attention must be paid to staking and tying the leading shoot, and the side flower-spikes should also be staked well out, so as to have the flowers as well arranged as possible. If large individual blooms are wanted the buds should all be thinned off except two on each spike; and, if for exhibition purposes, the spikes may be reduced also.

Out-door Culture.

Layering is the best mode of propagating Carnations when grown in beds; but the operation requires to be performed with some nicety. At the end of July or beginning of August, a quantity of light matter, consisting chiefly of leaf mould and sand, should be got ready; and a dressing of this, about 2 inches thick, must be laid round each plant. The layers are rooted in this, therefore the compost should be sufficient to embrace them all. The shoots intended to be layered should then be selected, and should be divested of their leaves, so as to leave a few inches of their stems bare. A split, extending through two joints of the bare stem, must then be carefully and evenly made up the centre of the shoot. This leaves one-half of the stem attached to the old plant, and the other half protruding like a small tongue, which must be pressed out so that the edges of the cut part may rest in the soil. It is necessary to place a peg close to the base of the layer, so as to keep it in position. Another spadeful or two of the mixed material must then be placed above the other, so as to cover all up to the bottom leaves of the layers, and a good watering should be given; after which no more attention is needed until they are well rooted. Some plants will supply a dozen or more shoots suitable for layering, which is not too many; while others may not have more than one or two. Pegs made from the common Bracken (*Pteris aquilina*) are the best I have used for pegging them with, and they decay quickly in the soil when no longer required. As soon as the young plants are rooted sufficiently to lift with plenty of ball, the stem which unites the young plant with the old must be cut with a knife. When lifted, they should be planted 6 inches apart each way, in a cold frame, in which some sandy soil has previously been placed to the depth of 4 inches. They must be kept close for a few days after being newly put in; but, when established, full air may be given them, excepting in wet or frosty weather, when they should be protected. During damp weather, mildew sometimes attacks them; and this has to be exterminated by sprinkling sulphur over the affected parts. Little water is needed at the root throughout the winter, and decayed leaves should be clipped, but not pulled; for, being very tough, the stem is frequently injured, and the roots disturbed in this way. If bad weather necessitates their being kept close during winter, they must be well exposed before being planted out, or they will be shy in starting into growth. Beds or borders intended for their reception should be manured with strong dung and deeply dug in autumn. About the end of March the surface should be stirred up and well broken with a fork; and, if the soil be dry enough, the young plants may be brought from the frame with balls intact, and planted out about the 1st of April. The soil must be firmly pressed about the roots; and, if cold cutting winds prevail afterwards, a few Spruce branches inserted in the bed here and there amongst the plants help greatly to protect them. The soil must be kept clear of weeds in summer, and the only attention the plants stand in need of when in full growth

is staking and tying the flower-spikes. If neglected in this respect they are very liable to get broken, as the stems are small and brittle, and the blooms large and heavy. What I have said regarding the Carnation is applicable to Pinks and Picotees; the latter name has arisen from the marking in the flowers, and the only difference which I know of in Pinks is that they require to be layered about a month earlier than the Carnation; and, instead of being kept in frames during the winter, they should be planted in September into the position they are intended to adorn the following season.

J. MUIR.

FORCING THE LAURUSTINUS.

Two of the most conspicuous objects in our greenhouse this winter have been two tall standard plants of *Laurustinus*. They have been grown in pots for several years, and stand upon the terrace during the summer, in a somewhat warm situation, where they make quite a profusion of flower-buds before autumn. By November they are moved into the greenhouse; and before Christmas, when the buds are just ready to open, they are again moved into one of the Vineries, where all the flowers open simultaneously, and, when seen through the glass at a short distance off, the plants might easily be mistaken for a well-flowered white *Ixora*. Outdoors, in the northern counties, except in certain situations near the sea, the *Laurustinus* never opens its flowers perfectly; or rather, I should say, the flowers on each truss seldom open altogether—some are fading while others are just expanding, which gives the head a weedy look, and renders them unsuitable for button-holes and bouquets. When forced in a slight heat just about mid-winter, the flowers, on the contrary, open freely, and have a pure white aspect, not surpassed by that of the *Camellia*, and the truss, being graceful in form, is most eligible for cutting for any purpose. A single truss backed up by its own foliage, a *Geranium* leaf, or a sprig of Maiden-hair Fern, is much esteemed for button-holes. As soon as the flowers are fairly out, we move the plants into a cool house, where they are available for cutting for about two months. It is not necessary that the plants should be grown as standards. Little plants from the borders, potted in spring, and grown in a warm situation during the summer, would do equally well, and perhaps be more generally useful for furnishing. Such plants may always be had cheap from the nursery; in fact, we have sometimes wondered that nurserymen did not make the pot culture of this plant a speciality. Of course, even young plants set their flowers freely when planted out; but, when grown in pots, they make a much denser bush, and the flower-trusses are much more numerous. We have no hesitation in advising those who require a supply of pretty white flowers during the autumn, winter, and spring months, and who desire to produce them cheaply and with certainty, to grow *Laurustinus* in pots.—“The Gardener.”

Chinese Primula Blooms Damping Off.—I would invite all growers of *Primula*, and amateurs especially, to keep a sharp look-out during damp weather for the first symptoms of that destructive mould that will, if unseen, soon destroy the finest heads of bloom. The mischief invariably commences in the tube of the flower, and is doubtless caused by moisture having settled there. Soon the flower droops and rots, and is somewhat negligently pulled away without thought as to after results. In the meantime, the mouldy virus is creeping gently down the flower-stem, until it reaches the base of the truss, from whence all the other flower-stems radiate; here it spreads rapidly over the whole stem, and, in a few days, the entire truss collapses, much to the disappointment of the grower. I have often seen the same thing occur in the case of a fine head of seed pods, and that too after much labour had been expended in the hybridisation of the flowers. The only possible remedy is to frequently look over the flower-stems on each plant, and, if any signs of damping are apparent, pinch them off clean below the affected part. Sometimes, too, when the rot has reached the base of the truss, I have saved the flowers by carefully cutting away the decayed part with a penknife.—A. D.

A Grove of Gardenias in England.—Good gardeners have so long grown *Gardenias* well in pots that probably few will expect much improvement in the cultivation of these plants. Mr. Philip Ladd, of Bexley Heath, however, has shown even more than his usual boldness and intelligence in dealing with *Gardenias*, and we have never seen a more interesting subject in its way than his *Gardenia-house*. This is about 140 feet long by 25 wide, and wholly occupied by *Gardenias*, healthy glossy bushes dotted over everywhere with their large and handsome green and white buds. The bushes are all planted out each on a mound of peaty soil, which rests on the hard floor of the house. Each plant stands on a hillock, and thus water may be abundantly used without injury. They do not root into the floor, but each bush finds its nutriment in

the barrowful of soil or so in which it is planted; with plenty of heat and moisture, and frequent syringing, the plants grow apace, and there is no mealy bug—their usual attendant and enemy—to be seen. On the floor and around the mounds the water lies in pools, as it might in a bog. The effect afforded by the bushes is like that of a healthy Coffee plantation, though, by and bye, when the white waxy blossoms are opening freely, it will be very different. This and other plantations made by Mr. Ladd seem to point to the probability that much improvement may be effected by planting out subjects now usually grown in pots.—W. R.

When to Sow Mignonette.—I have bought some seed of what is called Tanton's "New Prize Taker" Mignonette, and will feel obliged by some instructions as to when it should be sown.—AMATEUR. [Mr. Tanton says:—"For summer work sow in February in slight heat, and grow the young plants on in a warm light plant-house. For autumn and winter decoration, sow in March and April, in small 60-sized pots, three seeds being put in each pot triangularly; place the pots in a cool situation until the young plants are in the rough leaf; then remove all but one, and place the pots in full sunshine; as soon as the pots are full of roots, re-pot into pots larger in size, using as compost one-third turf and loam, one leaf mould, one road grit, well draining the pots, and staking the plant. As the side shoots progress, keep them pinched back in the same way as a Geranium, in order to make them vigorous and strong. During June, July, and August they should be kept in a situation with a north aspect, and should be sprinkled overhead; they will then have acquired sufficient size to be removed to a more sunny and open situation. The last stopping may be made the first or second week in September, when they may be exposed to the full rays of the sun in order to ripen the wood and set the bloom for the winter months. Early in October they should be placed in a cool airy greenhouse, close to the light, when the flowers will expand and continue to do so throughout the winter and spring months."]

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Two Varieties of Camellia Valtevareda.—With reference to "N. H. P.'s" note regarding this Camellia, purchasers should be informed that there are two varieties of it, one of which is much inferior to the other and seldom properly expands its flowers. Care should, therefore, be taken to secure the best variety.—W. H.

Orchids Now Open in the Exeter Nursery.—The following are at present in fine condition with us, viz.:—*Phalenopsis Schilleriana*, *P. amabilis*, and *P. grandiflora*; *Odontoglossum Pescatorei*, *O. nebulosum*, *O. Bictonense*, *O. Uro-Skinneri*, and *O. citrosum*; *Zygopetalum Mackayi*, *Lycaste Skinneri*, *Oncidium incurvum*, *Cypripedium barbatum* and *insigne*, *Dendrobium nobile*, *D. Dalbousianum*, *D. moniliforme*, and *D. speciosum*.—Wm. R. W. WOODMAN, *Exeter*.

Planting out large Camellias.—The present is the best time to plant out large Camellias. Before doing so, the old inert soil should be carefully picked out with a stick, or some sharp-pointed instrument, taking care at the same time not to injure the roots. Drain with broken bricks, and give 3 feet of good rough loam and peat in equal proportions. In this they will revel. After planting, give a good soaking of water to settle the soil.—J. SHEPPARD, *Woolverstone Park*.

New "Strain" of Chinese Primulas.—Mr. James, of Isleworth, has now in bloom a distinct strain of the Chinese Primula, raised from seed taken from Tomkin's Marquis of Lorne. The plants have remarkably close-set, compact foliage, the leaf-stalks, being much shorter than those of other kinds; the foliage thus forms a bouquet-like setting, out of which the heads of bloom just rise, and form a complete rounded cluster, only a few inches in height. The blooms are large and of good substance, and of a deep rosy-purple hue.—A. D.

Begonia Lapeyrouse.—This is an excellent winter-flowering sort, bushy and short-jointed. Its pale pink flowers are produced in great profusion during the winter months. Plants of it, raised from cuttings struck in spring or early summer, and grown on in a close, warm frame, or pit, till autumn, are more generally useful than older plants, especially for indoor decoration, for which purpose it is admirably adapted. It, like all the Begonias, succeeds best in a light, rich, and free compost, with good drainage, and is impatient of too much moisture in the dull days of winter.—J. E.

Aloe ciliaris.—This is a useful plant in greenhouses as a small climber, and one which ought to be better known than it is. It is slender in habit, and easily trained into all kinds of positions. Its graceful spikes of yellow and orange flowers are produced freely from January to March, and at intervals during other periods of the year. They vary from 2 to 4 inches long, and are set on foot-stalks from 6 to 8 inches. It grows freely in almost any soil, but flowers best if well exposed. If planted out it will often grow from 5 to 6 feet in a season, and will push freely if cut back.—J. CROUCHER, *Hammersmith*.

New Camellias.—The Jardin d'Hiver is one of those newer Continental kinds that are not as yet common in gardens, but it is one that is highly commendable on account of its compact pyramidal habit. It is free flowering, and produces fine large imbricated dark rose flowers. It has a habit quite distinct from all other kinds I am acquainted with, and anyone adding it to their collection of Camellias will, I am sure, be pleased with it. I think it is one of M. Ambroise Verschaffel's raising or sending out, as he sent it me amongst a large collection I commenced forming here a few years ago. General Cialdini is another beautiful imbricated flower, of perfect form, and a highly commendable kind of a bright carmine colour. It bears cutting, and buds freely. Matteo Malin is also a lovely variety; in colour it is cerise, with a white mark down the petal. This is really a most beautifully chaste flower, of perfect form, and no collection should be without it.—CHEVALIER.

THE AMATEUR'S GARDEN.

By THOMAS BAINES.

Kitchen Garden.—In this department a continuous supply through the season much depends upon the attention during the next few weeks in putting into the ground the numerous seeds that require it. The whole of the Potato planting should be brought to a close before the end of the month. If the seed has been prepared as advised some weeks back, it will be in good order. In planting the general crop, there are two courses to follow: either place the rows sufficiently far apart to admit of winter Broccoli, Cabbage, Brussels Sprouts, &c., being afterwards planted between the rows; or put the Potatoes far enough apart to ensure their well-being, without anything else between them. In the former case, the rows will require to be a yard asunder; in the latter, 2 feet to 2 feet 3 inches will be sufficient. I prefer the single-cropping system, as, when double-cropping is resorted to, the winter vegetables never do so well, and in many cases are too far apart when the Potatoes are removed. On the score of economising space, this double-cropping is evidently more loss than gain.

Sowing Seeds.—Sowings should now also be made of Cocoa-nut and Enfield Market Cabbage, green Curled Savoy, Walcheren and Early Cauliflower, and Veitch's Autumn Giant Cauliflower. Prepare the seeds with red lead, as advised some time back, to protect them from birds. A little Cos and Tom Thumb Lettuce should also be sown. Successional Broad Beans and Peas will now require putting in. Excepting where the vegetable ground is very limited, and there is a difficulty in procuring Pea-sticks, there is nothing to equal the tall Marrow kinds for furnishing a large and continuous supply, which does not come in altogether as the dwarfer-growing varieties do. Where the tall sorts of Peas are grown, and the ground is rich and in good condition, they will require 5 feet 6 inches space between the rows; this will be sufficient, and better than sowing farther apart with Broccoli or Celery between, as is sometimes done; such double cropping being here again no advantage, for the Celery, Broccoli, &c., so grown never has the necessary strength and vigour to withstand the winter that they have when grown by themselves. A row of Spinach can always be grown without any disadvantage between Peas so planted. Amongst winter vegetables there is nothing that is of more real use than Brussels Sprouts. To grow them well, the seed must be sown not later than the third week in March, so as to get the plants a good size early, planting them out where they are ultimately intended to grow as soon as they are large enough.

Onions and Parsley.—The main crop of Onions should be sown as soon as the ground can be got into proper condition. Select for this important vegetable a good open piece of ground that has been deeply trenched in the autumn, and the manure got well down, as this gross-feeding deep-rooted vegetable delights in plenty of manure at a considerable distance below the surface. If there happens to be at hand a good supply of manure from the poultry-house, in a tolerably dry state, an inch of this material scattered over the surface, with an inch of soot, is the best preventive to the attacks of the Onion-grub, in addition to its manurial properties; if it be not sufficiently dry, mix ashes with it; this mixture should be well forked in and mingled thoroughly with 8 or 10 inches of the surface-soil. After the ground has been so prepared, it should have the benefit of three or four dry days before sowing, immediately previous to which tread the surface firm; then with the line mark out the rows a foot apart and half an inch deep. Thoroughly good well-grown Parsley is always acceptable; and here, amongst the Onion crop, without any detriment to the latter, it can be produced in the best possible condition. In every third row of the Onions drop in a few seeds of Parsley, at intervals of 2 or 3 feet; slightly cover the seeds altogether, again treading the whole surface firm, finishing with running the garden-roller over it. Leeks should likewise now be sown—a small patch broad-cast; afterwards transplanting. More Radishes, Mustard, and Cress should be put in—always remembering that, to have these young and tender, sowings must be made at short intervals.

Frames, &c.—Give abundance of air to Cauliflower and Lettuce under hand-lights and frames; as also to Potatoes, Radishes, Carrots, &c., in frames. See that the heat to Cucumbers in dung-beds is kept up by sufficient linings, as any check through an insufficiency of warmth would seriously retard their progress and produce a stunted condition of growth, from which they are slow to recover.

Apricots, Peaches, and Nectarines.—The dull sunless February has had the usual beneficial effect in retarding fruit blossoms, which are a full month later than they were last year. The necessary protecting material for these fruits should at once be got ready, and put on as soon as the first blooms open. All Peach walls should be furnished with moveable copings, the best of which undoubtedly are the permanent iron brackets with moveable sheets of

glass, the only objection to this being its first cost. A very efficient and inexpensive coping may be made of three-quarter-inch Spruce boards; the brackets to support these should be flat wrought iron, an inch-and-a-half wide by half an inch thick; these should pass immediately under the stone coping of the wall, and, to render them more secure, ought to be bent down a couple of inches so as to clip the bricks at the back of the wall. Supposing that the permanent stone coping overhangs the front of the wall 3 inches, these iron brackets should extend 13 inches from the wall and be turned up at their outer extremity three-quarters of an inch, that is, the thickness of the boards. In the middle of this turned-up end, there ought to be a hole, that will admit a small screw, which must be screwed into the front edge of the board to secure it there. The brackets should be bent from the wall at an angle of 35°; the boards used should be 11 inches in width, which will allow of their slipping under the stone coping to a distance of an inch, the angle to which the brackets are bent leaving room for this. The light or heavy character of the shading material used will determine the distance apart of the brackets. In moderately high-lying dry localities, where, in addition to the boards, a light material will be sufficient, the brackets may be 8 or 10 feet apart. In situations of this description, old fishing nets, which can be had in most parts of the country at a 1d. or 1½d. per yard, and which, further on in the season, are very useful in protecting Strawberries, Cherries, &c., from birds, will be ample. These should be tacked to the front edge of the boards sufficiently close to leave no openings, and to prevent the wind blowing them against the trees, which would only do serious harm. They must be secured at the bottom; this can be done by inserting in the ground, 6 feet apart, stakes of the strength of a broom-handle, to which the nets are tied. This protection may, without injury to the trees, remain on from the first opening of the bloom until the fruit is fully set. For situations that are not exceptionally low, damp, and under the influence of more than an ordinary amount of spring frost, it will be found all that is requisite. I have had under such covering a full crop of Peaches and Nectarines during a season when we had 16° of frost, whilst the trees were in bloom; the atmosphere and the trees being quite dry at the time. There are some places so unfavourably situated as to require thicker protecting material than the above, such as stout canvas. Where this is necessary it should be made in lengths of say 25 or 30 feet, fastened with strong tacks to the front of the coping boards, and securely tied to stout stakes driven in the ground at the bottom. A thick covering of this sort, of course, must be removed in the daytime. This can be done by folding it up from the bottom, and laying it on the top of the coping board, where it must be secured by cords, at intervals of 8 or 10 feet, passing round the boards, to which they are nailed back and front; with these cords the canvas must be tied, to prevent its blowing about. A handy man, with a light ladder, will in a short time cover and uncover in this way a wall of considerable length. Heavy coverings of this sort are frequently fixed with rings on wires, top and bottom, to slide as curtains, the objection to which is that, however tight the wires are fixed, even when in short lengths, the weight of the curtains causes them to dip at the top, leaving an opening, through which the wind rushes on to the trees. Heavy coverings of this description will necessitate the supporting brackets being nearer together.

Herbaceous Borders.—Most of the plants here will now be showing above ground. The mulching materials, recommended to be spread on the surface early in the winter, should now be dug in. For this purpose a five-pronged steel digging-fork is preferable to a spade. Even in light soils, an implement of this description may be used. If the margin of the Grass adjoining requires edging-up, let it be done at the same time, so that the whole may look neat. In this spring digging, be particularly careful not to disturb the roots of Lilies of any description, as these plants, more than most others, especially at this season, cannot bear any mutilation of their roots. Shrubbery borders should now be hoed and raked over, so as to give them a clean and tidy appearance.

Houses.—The temperature of the stove should now be raised, keeping it 65°, or a few degrees over, in the night, with a corresponding rise by day; but in the mornings of apparent sunny days, reduce the fire-heat sufficiently early, so as to avoid the necessity of admitting much of the cold cutting air we get at this time of the year. Shade such plants as require it when the sun shines clear, as its effects on the young tender foliage is at this season calculated to do more harm than later on, when the leaves are more fully developed. Supply all the free-rooting quick-growing subjects here with a sufficiency of water at the root. Syringe the plants with tepid water early every afternoon, to keep down thrips and red spider, which the higher temperature will cause to increase apace if not kept in check by this means. In the greenhouse more water

will be required, especially to soft-wooded plants; here also do not admit side air, except in small quantities, when the winds are cold and piercing; but ventilate freely at the roof during the middle of the day. Pot Lilies of all kinds, the moment they show above the soil, should be brought into a light airy situation; keeping them even a very short time after they appear above ground in a dark or only partially lighted place appears to have two effects—it draws the shoots in a way that spoils their appearance, and seems also to curtail the root-forming capabilities of the plants; these weakened drawn stems always being deficient in surface roots—that is, roots from the stems above the bulbs, which these plants, when well grown, throw out in quantity.

THE FLOWER GARDEN.

LILIUM GIGANTEUM AMONG RHODODENDRONS.

My experience of the hardiness of this stately Lily for outdoor cultivation quite confirms that of Professor Owen, detailed in *THE GARDEN* of the 6th inst. (see p. 191). I purchased a small root of it four years ago, and kept it for two years in a cold frame, where it produced small healthy foliage for two successive years, but showed no indication of flowering, nor did it increase much in size. In the autumn of 1872, I planted it out in a bed devoted to American plants, in which the soil consisted mostly of peat, with a slight admixture of loam and leaf mould. In the summer of 1873, it made a vigorous growth of foliage, which was nearly all cut down in the succeeding winter. Last spring, a rich display of foliage was produced from three or four crowns, one of which threw up a strong flowering stem nearly 3 inches in diameter at the base, 7 feet high, and bearing thirteen flowers, all of which ripened seed. During the last year it seems to have quite doubled in size; and now forms a mass of seven or eight crowns, which are commencing to throw up foliage. The plant seems perfectly hardy under a most trying winter. My garden is 600 feet above the sea level, and during the last four months we have had a continual alternation of severe frosts and sudden thaws. The clump of *Lilium giganteum* has had no artificial protection, save a thin sprinkling of Cocoa-nut fibre, but the partial shelter afforded by the *Andromedas*, amongst which my Lilies are planted, has, I doubt not, been effective in sheltering them from excessive summer heat and winter frost. Under such circumstances, I believe the whole of the Lilies would be perfectly hardy in the open air, and an intergrowth of small ornamental evergreens (*Kalmias*, *Andromedas*, *Ledums*, *Heaths*, and small *Rhododendrons*), adds much to the effect of a bed of Lilies, which would otherwise be unsightly, except during a few weeks from June to August. In a mixture of rich peat and leaf mould, strengthened with a little loam, nothing can exceed the vigour with which nearly all the known species of Lily thrive with me in the open air, and the increase in the size of the bulbs is much more rapid than under pot culture. I flowered last year upwards of twenty species in the same bed as that containing *L. giganteum*. *L. pardalinum*, which was a single small bulb two-and-a-half years ago, produced four stems between 7 and 8 feet high, which, collectively, bore eighty-seven blossoms; and *L. Szovitsianum*, twenty-eight flowers on a single stem, *L. umbellatum*, and many other species were equally luxuriant; the only species that did not succeed with me in the open air were *auratum* and the varieties of *speciosum*; but this, I think, was due to the bad condition of the bulbs.

Bentham Hall, Broseley.

TREATMENT OF FUNKIAS.

FROM the scarcity of these plants it may be presumed that few people are aware of their worth for many kinds of decoration. They are all plants possessing handsome leaves, and the flowers being very delicate, both in form and colour, are more like those of some choice tender stove-plant than a hardy herbaceous one. Their requirements, like those of many hardy flowering plants, are few, and they grow to perfection in an ordinary herbaceous border. Their foliage decays in autumn, when, according to the depth they are planted, the crowns may be above ground or below it, but in either case they need no protection during the winter. When growth begins in spring, a top-dressing of light manure generally enlarges the leaves throughout the

summer, but without it, or in poor soil, they do not become diminutive or badly coloured; on the contrary, I think the colours in the leaves are better defined without the manure, which is apt to induce a gross growth. However well these plants may look in an herbaceous border, it is not the position they should occupy to be seen to the best advantage; or, indeed, to which they are justly entitled. When used in the flower garden, old crowns or young seedlings may be planted; and it is only necessary to lift them once in three years to enrich the soil in which they are growing. Seedlings may be planted in May, but old crowns need removing earlier than that. If the spring is mild they will push by the end of March, and this is the time to shift them if it be necessary. If they are to remain in the same quarters for several years the soil in which they are planted should be deep and somewhat rich. Seed, if sown now, will furnish handsome plants this summer; its seed will germinate although kept for several years, for I have some young plants coming up now from seed which I saved in 1870. The soil I use is a mixture in equal quantities of loam, peat, and silver sand, and so soon as the young plants are large enough they will be potted into 2-inch pots, in stuff very similar to that in which they were raised, but somewhat rougher. Attention to watering until bedding-out time will ensure good plants, and, as they do not grow to any great height the first season, an edging or second front row is the position for which they are most suitable. Here they will develop good crowns and plenty of roots by autumn, and the following season they will be sufficiently grown to fill a space where larger plants are needed. This may be amongst other foliaged plants, or in a bed by themselves; if the latter, each season's seedlings should be made to fill up the edgings, and the larger and older plants kept in the centre. Their habit and aspect is nearer that of some of the dwarf Cannas than anything I can compare them to, and their markings are varied and rich. They do not grow all one height. *F. japonica lutea variegata*, *F. ovata variegata*, *F. lancifolia*, and *F. lancifolia marginata*, are amongst the dwarfiest, while *F. Sieboldii*, *F. grandiflora*, *F. cordata*, and *F. sub-cordata* are much taller, yet none of them exceed 2 feet in height. The leaves of some are striped with bright golden-yellow and deep green. In others the colours are pure white and livid green. The flowers are produced on graceful racemes, which are raised prominently above the foliage, and their colours are pure white, lilac, and puce. The flowers add greatly to the value of these plants in the herbaceous border; but in the flower garden, where foliage is sometimes more needed than flowers, their fine foliage is the secret of their attractiveness. However great is the value of Funkias for the purposes above indicated, I consider them to be of still more importance for decorating the greenhouse, conservatory, or any other indoor place in the winter and spring months. To be in condition for such work at this season, they need to be forced into leaf; but this is easily done. About the end of October, the strongest and oldest crowns to be had should be lifted, and potted into 5 or 6 inch pots. The compost above recommended for the seedlings will do at this time, if a little light manure be added. The drainage should be sufficient to prevent stagnation at any time. The roof should be entirely covered while potting, leaving

only the crown above soil; and, when potted, the plants must be set in a cold frame, and covered up and treated similar to Hyacinths and other bulbous roots. Their root action begins while under cover, so that when placed in a temperature of 65°, about the end of November, the leaves soon expand. By January they are in good order for removing from the forcing-pit into any situation where exquisitely coloured leaves and lovely flowers are required. A couple of dozen pots may be started in succession, and they will last for four months.

VIOLA CUCULLATA.

AMONGST the various kinds of Violets, the three principally cultivated in gardens are the *Viola odorata*, *V. tricolor*, and *V. altaica*, and from these, especially from the last-named, have sprung a number of very beautiful varieties. There is, however, a fourth kind, originally introduced into our gardens about the end of the last century, which is well worthy of a place amongst hardy ornamental plants. This, says the "Revue Horticole," is the *Viola cucullata* of Elliot, a Violet which is unusually floriferous, and one which bears some resemblance to the common Violet, but unfortunately has not its delicious scent. It, however, flowers much more freely than the sweet-scented Violet, and its tufted foliage and elegant variegated leaves make it a valuable acquisition. It came originally from North America, and belongs to a section in which there are some fine varieties.

Viola cucullata.

THE AMERICAN COWSLIPS.

THE character of these beautiful hardy border-flowers is best represented by the common *Dodecatheon Meadia*, which is familiar to every one who has even a limited acquaintance with hardy flowers. All of them are striking plants, that should be cultivated in every garden; and though at present some of the sorts are scarce, there is no reason why they should be so, for, with ordinary attention to their cultural wants, they may be grown to perfection and increased abundantly. They will not thrive in all soils equally well, nor in every situation or aspect. They prefer partial

shade; nothing tries their strength more than full exposure to the blazing sun. The finest clumps of the common species which we have ever seen, says "The Gardener," had existed for years in the same spot, in bays formed in the outline of a wide border of American plants facing the east, and backed up by a dense belt of deciduous and evergreen trees of considerable height. In this position the American Cowslips had the benefit of the morning sun, and the cool shade of the shrubs and trees from the heat of the mid-day. It was a moist as well as shady position, and the soil had been prepared in the usual way for American plants. It was deep, and had been liberally mixed with peat, even to the margin, where those plants at least, in so far as they are represented by the shrubby tribes, had not been, and never were intended to be, planted, but where, as represented by the herbaceous natives of America, there were many fine examples, testifying, by their rich luxuriance, that they liked both the position and the preparations

that had been made for them. The border, in fact, had been designed for American plants only, shrubby and herbaceous alike; and little else was admitted into the collection of herbaceous plants brought together in it, except the more choice American species, including the diminutive shrubs of that country, which may properly be associated with herbaceous plants on the margin of such a border. Were I to prepare a spot specially for Dodecatheons, I would select a position similar, as regards shade and aspect, to that they enjoyed so much in the case just described. And if, as regards soil, I had to choose between a light dry shallow soil, and one which was deep and moist, and resting on a cool bottom of clay, I would choose the latter, being sure that the plants would like it best. Should the soil be clayey or very tenacious, it will be brought nearer their liking by freely mixing it with leaf mould, or good peat and old frame-dung in equal parts, and a liberal sprinkling of rough gritty sand. In any good free loam no such admixture will be necessary. Abundance of moisture in the growing season is of the utmost importance to the continued vigour and well-being of the plants, and if at any time during that period they should be liable to suffer from drought, let them be watered without stint, and mulched close up to the base of the leaves with rough leaf mould, old frame-dung, or anything of a similar sort that will serve to arrest excessive evaporation. They are somewhat impatient of frequent removal; and, except for the purposes of increase, they should not be often disturbed when they are thriving well. The best time to divide them is in the spring, when they are beginning to grow, and, except it is desired to make the most of the stock, do not divide very minutely. A single crown will form a plant, but only a weak one, very liable to be cut off by checks which would not in the least affect a stronger cutting. In planting the divisions, use a lighter and sandier soil immediately about them, so as to induce them to root freely the first season; and if they push their leaves before many roots have taken hold of the soil, give them the benefit of a little shade. A flower-pot inverted over the plants will be found as handy a means of protecting them from drying winds and overpowering light as any that can be adopted. They are capital plants for pot culture, particularly *D. integrifolium* and all the varieties of *D. Meadia*, and they may be easily forced into flower in February or March, if well established and strong plants. Grown in this way they are pretty ornaments for greenhouses.

ALPINE AND ROCK PLANTS WITH WHITE OR WHITISH FLOWERS.

I WISH to secure a good number of Alpine and rock plants with white or whitish flowers. Can you assist me?—L. M. [The following list includes all the good kinds in cultivation:—

<i>Achillea</i>	<i>Cardamine</i>	<i>Koniga</i>	<i>Ranunculus</i>
<i>Clavennæ</i>	<i>trifolia</i>	<i>maritima</i>	<i>rutafolius</i>
<i>Andromeda</i>	<i>Cerastium</i>	<i>Leucanthemum</i>	<i>Sagina</i>
<i>tetragona</i>	<i>Biebersteinii</i>	<i>alpinum</i>	<i>glabra</i>
<i>Androsace</i>	<i>grandiflorum</i>	<i>Leucojum</i>	<i>Sanguinaria</i>
<i>Chamaejasme</i>	<i>lanuginosum</i>	<i>vernum</i>	<i>canadensis</i>
<i>cylindrica</i>	<i>tomentosum</i>	<i>Lychnis</i>	<i>Saxifraga</i>
<i>helvetica</i>	<i>Chimaphila</i>	<i>Viscaria alba</i>	<i>affinis</i>
<i>obtusifolia</i>	<i>maculata</i>	<i>Menziesia</i>	<i>Burseriana</i>
<i>pubescens</i>	<i>Chrysanthemum</i>	<i>polifolia alba</i>	<i>ceratophylla</i>
<i>villosa</i>	<i>alpinum</i>	<i>Muscari</i>	<i>Cotyledon</i>
<i>Anemone</i>	<i>Convallaria</i>	<i>botryoides al-</i>	<i>diapensioides</i>
<i>alba</i>	<i>majalis</i>	<i>bum</i>	<i>granulata fl. pl.</i>
<i>alpina</i>	<i>Cornus</i>	<i>Myosotis</i>	<i>hypnoides</i>
<i>nemorosa</i>	<i>canadensis</i>	<i>sylvatica alba</i>	<i>longifolia</i>
<i>sylvestris</i>	<i>Crocus</i>	<i>Nierembergia</i>	<i>oppositifolia</i>
<i>trifolia</i>	<i>biflorus</i>	<i>rivularis</i>	<i>alba</i>
<i>Aquilegia</i>	<i>Cyclamen</i>	<i>Enothera</i>	<i>Rocheliana</i>
<i>cærulea alba</i>	<i>Coum album</i>	<i>marginata</i>	<i>Stansfieldii</i>
<i>Arabis</i>	<i>Diapensia</i>	<i>taraxacifolia</i>	<i>Scilla</i>
<i>albida</i>	<i>lapponica</i>	<i>Ononis</i>	<i>bifolia alba</i>
<i>petraea</i>	<i>Dryas</i>	<i>alba</i>	<i>Sedum</i>
<i>procurrens</i>	<i>octopetala</i>	<i>Oxalis</i>	<i>album</i>
<i>Arenaria</i>	<i>Erinus</i>	<i>floribunda alba</i>	<i>Silene</i>
<i>baccarica</i>	<i>alpinus albus</i>	<i>Papaver</i>	<i>alpestris</i>
<i>montana</i>	<i>Funkia</i>	<i>alpinum albi-</i>	<i>maritima</i>
<i>verna</i>	<i>grandiflora</i>	<i>florum</i>	<i>Silacina</i>
<i>Artemisia</i>	<i>Galanthus</i>	<i>Paradisica</i>	<i>bifolia</i>
<i>argentea</i>	<i>nivalis</i>	<i>Liliastrium</i>	<i>Symphandra</i>
<i>frigida</i>	<i>plicatus</i>	<i>Parnassia, in var.</i>	<i>pendula</i>
<i>Asperula</i>	<i>Helleborus</i>	<i>Phlox</i>	<i>Thlaspi</i>
<i>odorata</i>	<i>minor</i>	<i>subulata alba</i>	<i>latifolium</i>
<i>Aster</i>	<i>Hoteia</i>	<i>Potentilla</i>	<i>Thymus</i>
<i>alpinus albus</i>	<i>japonica</i>	<i>alba</i>	<i>Serpyllum</i>
<i>Astragalus</i>	<i>Hutchinsia</i>	<i>Primula</i>	<i>album</i>
<i>hypoglottis al-</i>	<i>alpina</i>	<i>cortusoides</i>	<i>Trientalis</i>

<i>alba</i>	<i>Jeffersonia</i>	<i>amplexicaulis</i>	<i>Zephyranthes</i>
	<i>diphylla</i>	<i>parnassifolius</i>	<i>Atamasco</i>

DRAIN GRATINGS.

THE accompanying is a sketch of what I consider the best mode of draining gravel walks or drives. The grating is not cast with the frame, but is set into it and works with a hinge, so that it can be conveniently lifted when the space between the bars becomes choked up, and admits of the sediment (which usually collects at the bottom of the cesspools) being taken out. As will be seen, the main drain is laid along the centre of the walk. The tile for this position is 12 inches wide. Two of smaller size conveys the water from the cesspool into it, and the mouths of these are placed a foot from the bottom of the cesspool, so that all the refuse which passes through the grating collects at the bottom, and is prevented from passing into or in any way obstructing the pipes or tiles. The cesspools are built with bricks, and the top is covered with a stone or thick flag, in which a square hole is hewn for the grating to be placed in. The level of the stone is slightly below the walk and verge level, and I

Walk-drains and Gratings.

like the part surrounding each eye to slope for a short distance into it, when the water, during heavy showers, runs in rapidly and passes away at once.

J. MUIR.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Saxifrages under Glass.—I have *S. oppositifolia* and its white variety now in bloom under glass; they have been out all winter, but having them in pots I have put them into my hardy plant-house that I might the better enjoy their beauty. Both are close creeping plants; but, of the two, the normal form is the more robust. Its flowers are bright red, and rather larger than those of *alba*. In the spring garden both these Saxifrages are very ornamental, whether they are in pots or vases, or upon rock-work. Later in the season, such humble plants would hardly be noticed; but to have them in bloom now, renders them specially interesting.—D.

The Winter Heliotrope (*Tussilaga fragrans*).—This is well worth growing in a warm dry corner in every garden; it soon establishes itself, and furnishes a good supply of its Heliotrope-scented flowers in February and March. This Coltsfoot is now flowering freely in a cool Fernery in Messrs. Veitch's Nursery at Chelsea, and it used to grow well in the gardens of the Royal Horticultural Society at Chiswick, where it had become naturalised on a dry bank in what was called the frame ground.—B.

Naked-flowered Jasmine and Japanese Honeysuckle on Birches.—Some time since, writes Mr. Johnson, of Belfast, in the "Florist," I planted some Birches (*Betula alba*) in the foreground of a garden view, and to each of them I put one *Jasminum nudiflorum* and one *Lonicera brachypoda aureo-reticulata*. These now form a pretty object 10 feet high, the golden flowers in winter and golden leaves in summer having a very pleasing effect.

New Way of Propagating *Echeveria metallica*.—This deservedly popular plant is readily increased by means of cuttings made of the flower-stalks, which, if inserted thickly in pans or boxes during summer, strike root freely; and although they do not make plants themselves, they form a quantity of side shoots, which, if taken off, make good plants in a very short time. I find this plan to be more expeditious than raising plants from seed. Any old plants that are getting too long in the stem may be safely cut down, and the crown will form a dwarf vigorous plant.—J. GROOM.

Gladiolus Brenchleyensis.—This is the best Gladiolus for flower garden decoration. In well prepared beds it flowers from the beginning of July until the end of September, and sometimes later if the autumn is mild. Its proper position is in the centre of a bed or the back row of a border, as the spikes often run up to a height of 3 feet, and look extremely handsome with their showy crimson flowers. The bulbs should be potted singly into 3-inch pots about the beginning of April, and started in a close frame, when they are in good condition for planting out about the middle of May.—J. MUIR.

Tree Lupines as Sea-side Plants.—I find, writes Mr. Johnson, of the Belfast Botanic Garden, in the "Florist," *Lupinus arboreus* to be one of the best of sea-side shrubs. In some ground-work which I had in hand, on rocks that formed a small promontory, I found it to be necessary to undulate the ground in order to secure protection for many plants, but *Lupinus arboreus* made good growth, produced its golden flowers in abundance, and firmly withstood the keenest blasts of winter in the most exposed positions. It likewise produced seeds, and hundreds of plants came up around, without any other care but that of letting them alone.

Ewing's Composition for Curing Mildew.—Last summer I gave this mixture a good trial, the great heat and drought having induced mildew to attack Verbenas earlier than usual. One syringing, with the mixture diluted according to directions on the bottle, however, completely cleared them of the pest; and by repeating the application at intervals of a month or so, we were enabled to keep the plants fresh to a very late period of the season. Where Verbenas are not yet given up as incurable, this mixture will be found infallible in keeping in check one of the greatest enemies to which this useful class of plants is liable.—J. GROOM.

THE FRUIT GARDEN.

GRAPE GROWING IN THE OPEN AIR.

(Continued from p. 170.)

THE varieties suitable for out-door culture are few in number, viz.: Black—Black Prince, *Black Esperion, and *Black Cluster; White—*Royal Muscadine and Pitmaston White Cluster. Those marked * are amongst the hardiest and best for the purpose. Black Prince is a fine variety, that seldom fails to colour well, but it is not quite so hardy as the others. I have not named the Black Hamburgh, but I would not dissuade anyone from planting a Vine or two of it as well, in favourable situations. One-year-old plants are best for planting, which may be performed in September or October, just before the plants go to rest, or in March or April, before the buds begin to move. The plants should be shaken out, and the roots combed out carefully with the hand until they are disentangled completely. A hole, about 4 feet wide, 6 inches deep, of semicircular form, and close to the wall, having been made, the Vine should be set pretty closely up to the trellis, in the centre of the hole, the roots spread out evenly in all directions, covered over with the soil, and watered if the soil be dry. When a long wall has to be planted, a continuous shallow trench should be taken out its whole length, and all the Vines planted at once.

Horizontally Trained Vines at the end of the First Year.

The length to which the newly planted canes must be cut back depends upon the system of training adopted, and there is no system so simple, or so well adapted for distributing the vigour of the tree evenly, as the horizontal. I have tried nearly every system recommended, and though the horizontal method is not always adapted for Vinery culture, it is, without doubt, the best for ensuring the regular breaking of the buds and an even crop. This is demonstrated annually here in one long Vinery, where the Vines—now about twenty years of age—are all trained in this manner. I believe it is also the system most generally adopted by the French, and adhered to probably as much for the sake of its perfect simplicity as anything else; it may therefore be safely recommended here. It will be remembered that in my last article I recommended that the wires should be stretched horizontally 18 inches apart. Each of these wires then represents a Vine. Supposing we have a quantity of one-year-old Vines to plant, I should select the weakest, and, presuming the bottom wire to be about 6 inches from the surface of the border, I should cut them

Vine at the end of the Second Year, before Pruning.

down to that length, so that after planting they would just reach the wire to be tied to it. As a great development of leaf and branch is not desirable, and it is important to cover the wall as soon as possible, these Vines need not be planted more than 12 feet apart. When the buds break, all should be rubbed off at an early stage but the two top ones near the wire. As these lengthen one must be trained along the wire to the right, and the other to the left, and when they have each grown about 4 feet they should be stopped. This will cause the buds at the axils of the leaves to get plump and mature, and also cause laterals to start from each joint, which must be pinched industriously beyond every leaf they make; but on no account must they be removed altogether, or the permanent buds, before mentioned, upon which the fruit depends the following year, will break, which would be awkward. This pinching must be kept up till the end of the season. I might have suggested the carrying of the main shoot along the wire till the plants met before stopping, but 4 feet each way, or 8 feet of the young wood altogether, will be ample; for the

sooner the shoots are stopped and pinching is begun, and the more persistently it is followed up, the sooner and better will the wood be ripened—for, next to heat, nothing hurries maturity so much as pinching. So much for the bottom wire, which we leave in the meantime to give our attention to the next one above it, which will be 2 feet from the ground. For this we select our next strongest Vines, cut them back to the height of the wire (2 feet), plant one between each of the bottom wire plants—which, as they were 12 feet apart, will now reduce the space between the plants to 6 feet. Rub all the buds off except the two top ones, and again train these right and left, and stop and pinch exactly as before. Lastly, take the remainder and strongest of the plants which are left, and again plant one between every couple; leave it long enough to reach the third wire, to which tie it, and train it like the others. This will finally leave the stems of the plants 3 feet apart, which is as close as is desirable, and the wall will be partially furnished from the bottom to the height of nearly 5 feet the year after planting, when the bearing shoots should be trained vertically, as will be described. By the above plan, I am, of course, assuming that good one-year-old canes are employed for planting, in which case a year is saved, as it is not necessary to cut the plants lower than the wires which they have to furnish. When the planting Vines are weak it is better to cut them all down to the lowest bud, and plant them 3 feet apart at the first. During the summer they must be trained vertically—one shoot from each—to a height of 4 or 5 feet, stopped and pinched; and in autumn, when the wood is ripe, they must be cut back to the first, second, and third wire in their respective positions, as above described; and the second year the horizontal—right and left—process may be commenced. To fill the top portion of the wall, new limbs must be originated from the highest branches on the first principle, or the first shoots may be simply continued backwards and forwards on the wires till the wall is covered. I should state here that, to prevent bleeding, the Vines should be pruned back to the desired length two months before planting. These directions for training apply to any kind of wall on which there is room for a few Vines; but where the space is narrow, as between windows for instance, or round doorways or porches, it is better to train the Vines vertically, treating them, as regards stopping and pinching, the same as the others. It may appear that I have recommended rather thick planting, but the object is to cover the wall quickly; for it must be borne in mind that the Vines are not likely to ripen their wood thoroughly to the extremities of the shoots in every situation, and it is only that portion of the wood which is brown and ripe that can be left at pruning time. It must not be expected, therefore, that the progress of the Vines will be as great as when they are grown under glass. Thick planting is, for these reasons, advisable at first, as a portion of the Vines may be considered as extras, to be removed as the others encroach upon them. Merely adding, that the roots should be well watered during the summer, when the soil appears to be dry, and that the foliage should be frequently syringed with clear soft water to keep them free from pests, I now come to the second year's treatment. This begins with the pruning of the Vines as soon as the leaves have fallen in autumn. Premising that each Vine has made two horizontal leaders, each a few feet in length—though disappointment must not be felt if the growth is neither lengthy nor vigorous the first year—the pruning consists in simply shortening these back to about 2 feet or 18 inches, or even less if the shoot has not ripened to that distance from the point of origin. The laterals also should be cut clean off close to the permanent bud, which must not be injured, and the operation of pruning the first season is finished. Afterwards, the border may be mulched with short litter or leaves, as a protection to the roots against frost; and if some Spruce branches, or loose bracken, tied here and there with strings, are hung over the Vines, it will be sufficient to save them from any ill effects, even in severe winters. By April the buds will be moving perceptibly, and by the time the leaves begin to unfold themselves danger from spring frosts will be almost past. While the young shoots of the Vine are still unopened, though they may be an inch or two in length, they will stand a lower temperature than many people suppose, and a very slight protection will be sufficient to prevent injury from April or May frosts even when the early leaves are out; but it is better to have some means of protection in readiness, such as a sheet of frigi domo, hexagon netting, or dry Fern or branches, just to hang over the canes at night. The frigi domo, even of the second quality, is the best, cheapest, and most lasting protecting material, and will shield a wall from the severest spring frost we are likely to have in this country when Vines are in leaf. Whatever the material may be, it should only be used against frost, and should never be drawn over the Vines at night till the sun has gone down, nor be left on in the morning after it has risen, in order that the sunshine may play upon the wall for as long a period as possible every day; for the real utility of a wall

depends upon the amount of sun heat it can absorb during the day, and the protection afforded by the radiation of the same during the night. The treatment of the leading horizontal shoot the second year is the same as in the previous year. It must be allowed to extend itself for 3 or 4 feet, tying it to the wire as it grows, and then be stopped, and be kept stopped, the laterals being pinched closely as before directed. The buds which break behind the point shoot—that is, on the portion of young wood that was left at pruning time—must be thinned out at an early stage to 9 inches or 1 foot apart, leaving the strongest as far as practicable. These are the shoots which will bear the bunches, if any, and they must be trained upright, and stopped at the first or second leaf beyond the bunch. This will cause them to throw out laterals both before and behind the bunch, and these must be pinched also at every joint till growth ceases; the object in out-door culture being to get a few well-developed leaves to each shoot rather than a crowd of foliage, which would shut out the sunshine from the wall. Originate the shoot, therefore, at the proper distances apart, stop them at the proper time, and keep them pinched, and earlier fruit and well-ripened wood will be the result. When the Vines come into flower, which will be in June or about that time, they must be guarded, during frosty nights and from severe east winds, with the shading, and care must be taken not to let them suffer for want of water at the root; only see that the water is not too cold. The chill may be taken off with a little warm water; but after July this will not be necessary. If the Vines are pretty strong and healthy, one bunch may be left to each shoot; and when the berries have fairly set, they should be thinned, taking care to cut out the small-looking berries, and to leave the larger ones, and not to overdo it, as the berries of the sorts recommended for outdoor culture are not of the largest size. The bearing shoots will hardly bear tying in before they are stopped; but when they will bend back to the upright position without breaking, they may be tied to a piece of bast or twine stretched from one wire to another for the purpose. After the berries are thinned, the general summer culture consists in attending to pinching and watering, and keeping the border clean, &c. If these matters are attended to, and if the border be mulched with some loose, dark-coloured material, such as Cocoa-nut fibre refuse or leaf-soil, that will prevent evaporation without reflecting, but rather absorbing, the sun's heat, there is little to be feared from red spider or thrips on Vines grown in the open air. In some situations I have heard of mildew being troublesome; and, when it does occur, dusting the leaves with flowers of sulphur by means of a sulphur distributor will generally check it. If all has gone right, the Grapes will be ripe in September or October, according to the locality and the varieties grown; and probably the wasps will be the first to make the discovery. To save the fruit from these pests it is not very troublesome or expensive to enclose each bunch in a thin muslin bag, and the fruit can then hang on the Vines till wanted. The fruit will stand as much cold, or, indeed, more than the leaves, and, while the latter remain on the Vines, the bunches are in no danger, and frosts may be warded off by shading, which will also help to ripen the wood. The pruning of the Vines at the end of the second year differs in no way from that of the previous year, except that the upright or bearing shoots require to be cut back to the base bud; and when the horizontal limbs come eventually to be furnished with these their whole length, the annual pruning consists in simply cutting all off in the same way. In conclusion, though I am not going to recommend heated walls, as that would be next to recommending a Vinery, and my object is to encourage anyone to grow Grapes without further expense or trouble than is involved in the culture and training of the plant, I would remind those who have a warm wall, or a gable behind which is a kitchen fire perhaps, and a flue, that they possess great advantages, and that, in fact, success is certain, other circumstances being favourable. I may also state that, where a wall is devoted to the purpose, it should have a good tile or wooden coping projecting about 9 inches or a foot from the wall. To this it will be easy to fix the shading by means of pulleys, and if a slender rail is fixed every 12 feet or so, with one end in the soil 3 feet from the wall, and the other nailed to the outer edge of the coping, it will serve for a support to the shading when it is drawn up, and it can be tied to a nail at the bottom during the day. When this means of protection is adopted, the greater the body of air between the sheet and the wall, the greater the protection afforded. On a wall covered in this manner, and regularly attended to, I have seen excellent Peaches ripened in the north, where it would otherwise have been impossible.

J. S. W., in "Field."

The Japanese Persimmon.—General Capron, formerly Commissioner of Agriculture, and since for several years residing in Japan, states that "the Persimmon is the best of all the native fruits of that country, and well worthy of introduction into the fruit gardens of temperate climates." The tree is described as finely shaped, having a rich, dark green foliage, and is an ornament anywhere. It comes into bearing from seed in Japan in from six to eight years.

RUSTIC HUTS AND ARBOURS.

In an extensive and picturesque park or garden shelters of various kinds are often indispensable. A "bird-minder's" hovel, where Grass or other seeds have been freshly sown—a covered shed for forester's tools, to prevent the necessity of their being carried long distances—or a general labourer's or woodman's hut in distant plantations, where the mid-day meal may be taken to them by a wife or children, are all more or less necessary in extensive gardens and woods. But, in gardens of every size, bowers and wigwam-like structures, such as shown in our plate, are desirable for many reasons. Such structures but too often appear in the shape of glaring red brick sheds, with naked slate roofs, forming offensive spots on the landscape by their blank ugliness and generally unsuitable character. When a naturally picturesque scene is disfigured by excrescences of that kind it is always very regrettable, as it would be so easy to impart to such features a pleasing aspect. The woodman's hut, in the annexed engraving, is a graceful example of what is meant. Here is a structure within the grateful shade of which three or four men might get a comfortable meal, sheltered from the sun and heat of summer, or the bleak winds of winter; or in which they might take temporary shelter from a drenching shower. Let us compare, in imagination, this picturesque object with a shed of any kind, having a bare prosaic roof, and there need be no hesitation in deciding at once in favour of the rustic hut. Such a structure as that which has furnished the artist with a picturesque subject for his clever picture may, with a little taste, be put together easily and cheaply; indeed, it need not involve a tenth part of the cost of the very ugliest brick shed. It is only necessary to get together a sufficient number of rough, unbarked poles, or tolerably straight branches, of any kind, so that they are of sufficient dimensions, and these will form the chief part of the material required. To put the intended structure together firmly and steadily, a circular shallow trench, from 9 inches to a foot deep, should be dug, of the size required, leaving an undug space where the entrance is to be. A circle of about 10 feet in diameter will be found a convenient size for a hut composed of waste timber of the kind above described. As the first step, in arranging the rustic timber-work, let three of the most suitable poles be selected; and when the thick ends have been placed firmly in the shallow trench, lean their points towards each other, so as to meet in the centre; and then humour their knots, or stumps of branches, till they lodge firmly against each other. Two of the three poles, thus fixed in their places, should be on either side of the entrance, and the third in the middle of the back. Other poles may then be added in a similar manner, till the circle is complete, all but the entrance; and the structure will then have assumed a well-defined tent-like form. The poles should be well wattled together with tough withies near the top, from the inside, in order to prevent the possibility of their slipping out of place. The next process may be an outside clasping, composed of the most gnarled and picturesquely crooked branches than can be got. This clasping should be placed about two-thirds of the height from the ground, forming a wreath of branch-work, passing close above the entrance, and well whipped on to the main poles with tough withies. The pile may then be further strengthened by the addition of another set of lean-to poles wherever the first set have not pretty well shut out the daylight. By this means, crannies will be stopped; the external wreath of branch-work will be still more firmly fixed in its place; and greater stability afforded to the whole structure. The shallow trench should now be filled up, inside and out, and firmly trodden down, when more earth may be heaped against the outside, to any height required, either for effect, or for the purpose of affording more warmth and shelter to the interior. The structure will then be found sufficiently firm for a ladder to be leaned against it, for the purpose of completing the rustic roofing, which may be formed of sods of fibrous turf; and the cavity formed by the meeting of the poles at the top may be filled with stiff gravelly clay, which will form a central reservoir of moisture for the nourishment of the turf, till a natural growth of Moss and Lichen furnish the rugged roof with other and more permanent tones of grey and green. The seeds of straggling, picturesque weeds may also be scattered in the roofing turf,

THE WOODMAN'S HUT.

such as the common climbing Galium, and many other hardy stragglers that do not require much moisture. These will soon form picturesque tufts and streamers, producing a wild and graceful crown of greenery, in harmony with the rugged fashion of the structure. In the raised bank, a plant of Clematis Jackmanni may be placed, and left to itself to find its way among the weedy growths, with which its straggling habit will cause it to harmonise as one of themselves, while flaunting its glorious blossoms in open defiance of their humbler display. A root or two of variegated Ivy may also be planted in the bank, and left to trail down, or climb upwards, as chance, or the nature of the situation may invite. In spring, a few seeds of major Convolvulus may be sprinkled in round the bases of the poles, and, towards May, perhaps, a strong plant of Cobæa scandens might have a chance of making its way up, and suspending its great purple bells among the other living features, with good effect. A couple of labourers, either after the fashion of Mr. Ruskin's amateur road-makers at Oxford, or even of the usual agricultural class, if assisted by a little tasteful instruction, calculated to improve both the teacher and the taught, would be able to put up such a structure within the sunlit hours of a long summer's day. The pleasant task of setting up a picturesque hut, either in the outlying copses of a park, or in the wilder part of a garden wilderness, would be more than repaid, if any reward beyond the mere enjoyment of doing were required, by the pleasure its aspect would not fail to give to others. Let any reader of THE GARDEN take another look at our woodman's hut, and say if it stood near a by path through a pretty wood, and a travelling sketcher got a peep at it, whether he would not at once plant his camp-stool in a good position, take out his sketching block, make his moist colours accessible, and set to work at once; and thus the pleasant day's work of building the hut might, beyond its intended purpose of local use and ornament, furnish the subject of a picture, which, if wrought by a skilful hand, might prove an attractive gem at the next ensuing exhibition of the Royal Academy, and fill the artist's pocket with bank notes. There is a hut, formed with branches after this fashion, in the Glasnevin Botanic Gardens, at Dublin, and in summer, when covered with the large leaves of the Aristolochia Sipho, the effect is very charming. H. N. H.

Paper Protectors.—Mr. Bréhaut remarks that his crop of early Potatoes under glass has been completely saved by the use of newspapers spread over the haulm during the late severe weather, while that of his neighbours, without this protection, has been lost. The extent of defence afforded by paper protectors is almost unknown as yet. The newspapers were suffered to remain on during the succeeding sunshine, so as to avert sudden changes of temperature. Where additional protection is needed, it would be easy to paste together any convenient number of newspapers, and fold the edges over twine (as a boy does for his kite), and these, suspended some inches above the others spread over the haulm, would enclose between the layers enough fixed air to protect anything.—“Florist.”

Pears in Succession.—A correspondent of the “Horticulturist,” says he has been supplied with excellent Pears from the 15th of August to Christmas by the succession offered by the following sorts:—Bloodgood, Seckel, Flemish Beauty, Belle Lucrative, Duchesse, Vicar of Winkfield.

Multiplying the Fig.—M. Rivière recommends a method of propagating the Fig by burying shoots in the ground to a depth of about a foot before winter. The following spring the branches are cut into several pieces, each one of which becomes a cutting, which is completely inserted in the soil. These cuttings make very strong plants during the current year.

Re-grafting Old Pear Trees.—There are many old and worthless Pear trees in almost every neighbourhood that could easily be made a source of pleasure and profit at little expense. Grafting is not very difficult. Cut off the limb, split it, open the split with a small wedge, insert a piece of the limb of the kind wanted, cut like a wedge—say 3 inches in length—putting the inner edges of bark in both graft and limb together, then cover carefully with wax, and nearly all will grow. The wax is easily made. Melt together in a kettle, 1 lb. of tallow and 1 lb. of beeswax, then 4 lbs. of resin; when melted, pour it into a pail of water, and pull it till well mixed.—“Cultivator.”

An Orange and Sugar Cane Garden.—The Magnolia Sugar plantation, 45 miles below New Orleans, is said to be one of the finest plantations of its kind in the world. It is devoted exclusively to the raising of Oranges and cane. The product from the cane of this plantation for 1874 was about 750,000 pounds of sugar and 750 barrels of syrup. The Orange orchard numbers 7,000 trees, and extends for a mile along the river. There, during the month of January, were picked and shipped 1,100,000 Oranges. The trees which thus bear so abundantly, are from four to fifteen years old, the oldest being some 25 feet high, and bearing at one time some 5,000 Oranges.

THE GARDEN IN THE HOUSE.

DINNER-TABLE DECORATIONS.

WITH reference to these I remember, some years ago, when the Royal Horticultural Society first offered prizes for the best plants for that purpose, it was stipulated in the schedule that they must be standards, with, I think, a clear stem 21 inches in height. Now, I do not think that this estimate of the applicability of standards for dinner-table decoration has been generally endorsed. I considered then, and nothing I have seen since has altered my opinion, that a plant with a pendulous or weeping habit may safely be mounted on a naked stem, either by grafting or training; but that plants of a stiff erect-growing habit have a most unnatural appearance when trained as standards, no matter how skilfully done. The plants most generally appreciated for this purpose are low bushes or pyramids, with a pair of weeping standards as central plants; always, of course, making due allowance in their selection for the size of the table. With reference to placing the pots under the table, and bringing the head through, it is not always convenient, even when desirable, to do so; but, for large public dinners or wedding breakfasts, it admits of the introduction of larger plants than would be otherwise possible. In this way I have seen large Palms used as central objects with a good result, as their foliage would be lifted well above the line of sight, with the effect of almost creating the impression that the dinner or breakfast was taking place in a Palm grove in the tropics. In providing the various materials for dinner-table decoration, it should always be borne in mind that the guests that usually assemble in a country mansion remain for several days; hence it is desirable that a change in the style of arranging the decorations should frequently take place. I do not mean a mere alteration of the disposition of the same materials, but a complete change of the whole arrangements. Thus, for instance, the leading feature in one arrangement might be cut flowers and foliage, arranged in suitable glasses; another in which plants in vases might predominate; another in which decorations on the cloth might be largely resorted to, or various combinations in which all three were more or less represented, would give abundance of opportunity for relieving the sameness that too often exists. I am not denying that this will involve some little trouble and forethought, but not much more than has generally been given to it where it has been fairly well done; and, as the propagating season is at hand, an estimate should be formed now of the probable requirements, and provision made accordingly. The truth is, what is really wanted is more variety; for, looking upon the same table, arranged in the same manner, perpetually, or only so slightly modified as to pass unnoticed by casual observers, creates an irrepressible desire for a change of some kind. What is usually understood by decorations on the cloth consists, first, of a free use in various designs, either in the form of bases for the lights or in flat groups, of coloured foliage obtained from the following and other plants:—Coleus, Crotons, Caladiums, Cissus, Begonias, tricolor and bicolor Geraniums, Abutilon Thompsoni, &c.; and, secondly, of dwarf compact masses of growing plants, of which I will speak more fully presently. I should, however, state, first, that a number of pans, made either of tin, glass, or earthenware, will be required. They should have holes through the bottom to permit surplus water to escape, and should be either circular or elliptic in shape, and not more than 1½ inch deep. They might be made in sets of various sizes, and, if made of tin, should be painted to preserve them. They might also be filled in sets; thus one set might be filled with the graceful low-growing Club Moss (*Lycopodium denticulatum*). Small bits dibbled in thickly now, in light sandy soil, and placed in a damp, shady position in a warm house, will soon run over the sides of the pans and completely hide them. *Lycopodium cæsius* may be treated in the same way; only this, being a stove species, will require more heat. When well done, the bluish metallic lustre of its foliage has a rich effect by candlelight. Masses of the white-veined *Fittonia* would form a pleasing variety, as would also the pink-veined leaves of *Gymnostachyum Verschaffelti*. Chopped Sphagnum or Moss should be freely used in the compost for these, and they might be raised just a little in the centre. Several of the low-growing *Alternantheras* might be suitable for using occasionally when more colour was required; but in all cases where erect-growing plants are used, a narrow edging of some creeping plant should be planted next the edge of the pans, as the object should be to have all completely covered. The new Golden Chickweed is another desirable plant for this purpose, as it forms a thick, close growth with a little attention, and has a naturally creeping habit. Although it loses much of its colour in winter, it will be very effective in summer and spring. The golden Thyme and some of the Sedums will also be available; in short, there is no lack of suitable plants. Whenever it is desirable for a change to introduce flowers low on the cloth, nothing has a more beautiful effect than a few pans of Moss

dressed thinly with Roses arranged in various colours, the blooms nestling singly in the Moss, allowing the green setting to show itself surrounding each flower. In the winter season Camellias might be used in the same way, and many other flowers also. Dwarf well-furnished plants of Maiden-hair Ferns in vases, make capital bases for the arrangement of choice cut flowers for the dinner-table, such as Roses and Camellias; and where height and breadth is admissible, I like those better than the Club Moss, as a base for the arrangement of the dessert. I do not think the present custom of placing the dessert on the table has anything to recommend it. The dishes, although intrinsically valuable, are often ugly in shape. I have often thought it would have a better effect, so far as appearance went, if the fruit used in the decoration of the table were arranged on bases of Club Moss, similar to those I have endeavoured to describe, and were allowed to remain till dinner was over, whilst a dessert to hand round might be arranged on a sideboard, or introduced afterwards from a cool room shortly before it was required. It is, I suppose, placed on the table simply for show, or to carry out a whim of fashion; and I think, so far at least as the fruit is concerned, the arrangement I have alluded to would be more effective, whilst the dessert for use could be arranged in the china dishes and handed round; neither would there be much waste or extravagance in so using the fruit, for there is usually at such times a large demand for jellies, &c., and all spare fruit from the dessert could be used for that purpose, instead of fresh.

E. HOBDAV.

Darwin's Abutilon.—Though new at South Kensington, this plant is not altogether so here in Dublin. We, and doubtless many of our readers, had the pleasure of making its acquaintance growing and flowering freely out of doors in the open border at Glasnevin during the autumn of the past year. We were at first sight much taken with it, and very favourably impressed as regards its value, not alone as a plant for indoor decoration, but further in respect of its adaptability for outdoor use, and playing an effective part in the flower ground during the summer and autumn months. It is very distinct in appearance and habit from the other species of the genus with which growers are familiar. Instead of being somewhat lanky and straggling as they are, it is of a very compact, dwarf habit, and the foliage instead of being thin, flimsy, and smooth, is stout, substantial, large, and somewhat pubescent. In shape the leaves are pointedly three-lobed. The wood is short jointed, and from every axil the flowers are produced freely. In the matter of size, colour, and appearance, the flowers are very much like those of the old *A. striatum*, except that in those of the plant under notice the colour is of a darker orange. In the production of flowers it is so precocious that before it grows a span high it is a flowering plant. When we first saw it out of doors at Glasnevin the plant then was not more than nine inches high, and yet it was blooming profusely. Dr. Moore, unwilling to risk his plant by putting it to the winter test, had it lifted early in November, in full flower, and housed, and, notwithstanding the disturbance, when we again saw it some time after, it was flowering, and has, we believe, continued to flower ever since.—"Irish Farmers' Gazette."

Ricinus Gibsonii.—This, introduced by Messrs. Veitch, is described as being distinguished from all other varieties by the intense deep red colour of the foliage, which reminds one of the dark-leaved varieties of *Amarantus*, now so much cultivated. It grows from 4 to 5 feet high, and has a fine branching habit. It will undoubtedly take a high position in the sub-tropical garden on account of its bright hue, which is retained during the entire season. It is a native of the Philippine Islands, and is named in compliment to the late Mr. Gibson.

NOTES AND QUESTIONS ON THE GARDEN IN THE HOUSE.

Adiantum Farleyense for Hair Decoration.—It may not be generally known that fronds or parts of fronds of this Fern, when fully matured, answer admirably for ladies' evening head-dresses, and that immediately submerged in cold water when done with for the evening, they will be as fresh and good the second night as when just cut.—RICHARD NISBET, *Aswarby Park*.

Geranium echinatum.—This *Geranium* differs from many others in its wood being thickly set with spines like that of a Rose. Its tiny white and magenta-spotted flowers are very pretty and becoming for button-holes. It is much grown at Chilwell for this purpose and for making bouquets, into which it can be very easily wrought, as the flower-stalks are from 10 to 12 inches long.—M.

Water Convolvulus.—In answer to "International," allow me to say that there is no meaning in this term, which can only be a local misnomer. None of the *Convolvulus*es or Bind-weeds, are aquatic; quite the reverse. If the great Bind-weed once gets into a shrubbery, it is impossible to eradicate it; and common people in the north, for this reason, call its troublesome roots Devil's-Gut. The term mentioned is not given as a synonym, or local name, in any book that we know of. If the plant is a pure aquatic, it is very likely to be the common Frog-bit, a favourite plant for an aquarium. It has large white flowers, yellow in the centre, above the surface of the water. Why not show it to some botanist?—J. P.

TREES AND SHRUBS.

NOTES ON BEECHES.

THE genus *Fagus*, or Beech tribe, comprises several species, of which only one, the common Beech (*Fagus sylvatica*), is indigenous to Europe. The New World possesses the largest number of species, viz., *F. americana* and *F. ferruginea*, in the United States; *F. obliqua* and *F. procera*, in Chili; and *F. antarctica*, in Patagonia and Tierra del Fuego. An indigenous species of Beech (*F. Cunninghami*) is found in the temperate regions of Australia, where it is known to the colonists as Native Myrtle. It is a large, handsome, evergreen tree, and attains a height of 195 feet; its timber is hard, beautifully veined, and much esteemed by furniture makers. In the temperate mountainous part of Java there are two species of Beech, viz., *F. javanica* and *F. argentea*. With the exception of *F. antarctica*, which is a stunted evergreen tree, with dense brown foliage, all these species of Beech are large, handsome, hard-wooded trees, yielding valuable timber. The nuts of the two Javanese species form a favourite article of diet with the natives of that country. In America the nuts of *F. ferruginea* are very generally used as a dessert. *F. obliqua* and *F. procera* have been introduced into various parts of Europe, where they have become acclimatised. Both of these trees are justly admired for their stately crowns and beautiful green foliage, which render them desirable ornaments in parks and large pleasure grounds. The common Beech (*F. sylvatica*) is found in most parts of Europe, and it is also very generally distributed over the northern and eastern States of the American Union. It is one of the handsomest and most valuable of our forest trees. Its trunk is erect and massive, and its height usually from 100 to 130 feet. The roots spread for 10 or 12 feet round the tree, but none of them go deeply under the surface, except the tap-root, which penetrates perpendicularly into the earth for 3 or 4 feet. The branches have a more or less upward tendency, and form a symmetrical and majestic crown. Upon young trees the bark is of a greenish-grey hue, but as the tree matures it assumes an ash-grey colour. Both leaf and blossom buds are long, cone-shaped, sharp-pointed, and consist of eighteen or twenty brown, slightly fringed scales. The leaves, when young, are soft and delicate, and of a beautiful yellowish-green colour, but, as the season advances, they become deep green. In October they become yellow and dry, shrivel up, and fall to the ground. Upon young trees, however, the withered leaves often remain until they are forced off by the swelling of the fresh buds in spring. The male catkins, which are in general four to a bud, have long drooping peduncles, and consist of about twenty greenish-yellow florets. The calyx of each floret is regular, bell-shaped, monosepalous, and divided at the top into five segments. There is no corolla, and the calyx usually contains twelve yellow anthers. The female blossoms, which appear in pairs upon the young shoots, consist of sharp-pointed catkins, broad at the base, and provided with numerous hairy monosepalous calyxes. The fruit, which is ripe in October, consists of rough spring capsules, each of which contains two or three smooth triangular brown nuts. The northern limit of the common Beech in Europe is 60°, and in America 51°. The highest elevation at which it is found is 5,000 feet above the level of the sea, but it does not seem to thrive well at a greater altitude than 2,000 feet. In Thuringia and among the Harz Mountains noble Beeches, 100 feet in height, are found at an elevation of 1,800 feet. The finest Beech forests in the world are situated in the island of Rügen, on the dunes of Denmark and Mecklenburg, and on the plains and low hills of Germany. It is in these regions, where Beech forests cover many thousand acres, that the tallest living Beeches are to be found. In the last century, Beeches 174 feet in height were cut down in North Germany, and at present many single trees exist there which are 136 feet high and 41 feet in circumference. Beeches thrive best in a surface-soil of poor, dry, sandy loam, with a sub-soil of chalk mingled with gravel, sand, and small stones. Those trees which grow upon mountain slopes, or on low humus-covered hills, with a northern or eastern exposure, yield the best timber. Beeches are generally propagated by means of seed, and young trees suffer much from frosts and

droughts, and in damp marshy situations. Mice and mole-cricket are also very destructive to the roots of young trees. The Beech attains its full height when about 100 years old, and then lives in perfect vigour and health for 200 or 300 years. Trees of this age are generally from 10 to 15 feet in circumference, and contain from 10 to 12 cords of timber. A cubic foot of fresh-cut wood weighs 65 lbs.; but this, by thorough seasoning, is reduced to 41 lbs. or 39 lbs. In damp poor soils, Beech trees frequently perish from internal rot between their seventieth and ninetieth years. Of the common Beech some very ornamental varieties may be met with in cultivation—as, for example, different kinds of weeping Beech, the variegated purple and copper-leaved kinds, and the Fern-leaved Beech, the leaves of which are cut into narrow segments, resembling the fronds of a Fern. These are almost wholly used for purposes of ornament, for which the common Beech itself is well adapted. The products of the Beech are numerous and valuable. The timber, which is heavy, hard, firm, and durable, is employed in the manufacture of numerous implements, tools, and articles of furniture. On account of its brittleness and liability to the ravages of insects, it is seldom employed for building purposes. The timber of the common Beech is inferior to that of *F. americana* and the two Chilean species already mentioned. Beech timber is especially adapted for sub-aqueous structures, or for positions in which it is not exposed to the action of the atmosphere. As fuel, the Beech is very valuable, and is surpassed in heat-giving qualities only by the Hornbeam and Maple. The charcoal of the Beech is highly esteemed on account of the equable heat which it emits. The bark is useful to tanners, and from the ashes of the wood excellent potash is obtained. In Denmark, Sweden, and some parts of America, the leaves of the Beech are carefully picked, dried, and used to stuff bed-ticks and pillows. The leaves and ashes form an excellent manure for grass and clover lands. The husks and nutskins contain a very poisonous material known as *fagin*. The nuts themselves form a favourite food of some birds and quadrupeds, red deer being especially fond of them, and they are also, in some countries, boiled, dried in the open air, parched by artificial heat, and ground into meal, from which bread and soups are prepared. The nuts have a pleasant sweetish flavour, and are very oleaginous. Considerable quantities of oil, resembling Almond oil, are obtained from them by pressing. From 100 lbs. of nuts, 12 lbs. of pure oil, and 4 lbs. of coarser oil are obtained. The former is of as good quality as the best Olive oil, and the latter makes a useful lamp oil. The refuse furnishes a good food for pigs. The best season for felling Beeches is the month of December. Beeches are very liable to be attacked by insects, the most destructive of which are *Phyllobius argentatus*, *P. micans*, *P. maculicornis*, *Rhynchænus coryli*, *Orchestes fagi*, *Melolontha fullo*, *M. solstitialis*, *M. hippocastani*, and *M. vulgaris*, all of which subsist on the leaves of the tree; the three last named frequently denude the tree entirely of its foliage. *Anobium tessellatum*, *Buprestis fagi*, and *Ptilinus pectinicornis*, may be named as very injurious to the wood. The most destructive,

however, are *Buprestis tenuis*, *B. nociva*, and *B. viridis*, all of which penetrate and cut the wood. The following butterflies also live upon the Beech in their grub state: *Bombyx æsculi* and *Cossus ligniperda*, in the wood; *Bombyx monacha*, *B. purdibunda*, *B. neustria*, *Geometra defoliaria*, *G. pusaria*, and *Tortrix splendana* upon the leaves. Numerous other beetles besides these already named also inhabit the tree, but all of them are harmless. The squirrel and dormouse frequently make their home in the Beech, and among its branches may be seen the nests of the wood-pecker, raven, jay, finch, and titmouse.

JOHN HUTCHINSON, M.A.

FRUIT OF TORREYA MYRISTICA.

THE drupaceous fruit of this plant, figured by M. Carrière in the "Revue Horticole," is so singular that we reproduce it. It usually

Fruit of *Torreya myristica*.

ripens about the middle of September, and then drops, leaving a capsule which dries up. When the fruit has attained full development, the branch that bears it appears to be much exhausted. The leaves become yellow and then fall, and subsequently the branchlets themselves die. A plant of this kind of Yew was planted about eight years ago in the open air in the establishment of MM. Thibaut & Keteleer, at Plessis, Piquet. It is now about 19 feet high, and its stem, which is furnished with branches from top to bottom, measures about 18 inches in circumference, and these branches are covered with leaves in such a way as to form a compact green mass, which has a very beautiful appearance.

AMERICAN AND BRITISH LARCHES.

IN the northern parts of the United States, Hackmatack is the name given to the Larch. The French Canadians call it *Epinette Rouge*, and the numerous descendants of the Dutch in New Jersey know it as *Tamarac*. The locality of both the European and the American Larch is more strictly confined than that of any other resinous tree of the northern zone of the two Continents. Michaux describes the American species as being most abundant in Vermont, New Hampshire, and the district of Maine; but though the soil is well adapted to its growth, and the winter is long and severe, it does not form the hundredth part of the resinous growth, which consists principally of the Black Spruce, the Hemlock Spruce, and the Red Cedar. It is only beyond the St.

Lawrence, particularly near Lake St. John, and the Great and Little Lake Mistassin, that it begins to abound, and to form masses of forest, some of which are several miles in extent, and it is abundant in Newfoundland, in nearly the same latitude. New Jersey, Pennsylvania, and the coldest and gloomiest exposures in the mountainous tracts of Virginia, are the limits of its appearance toward the south, but it is rare in these States; and in Lower Jersey, in the vicinity of New York, it is seen only in the swamps of White Cedar, with which it is scantily mingled. In Vermont and the district of Maine, the Larch grows only in low and moist places, and never on uplands, as about Hudson's Bay and Newfoundland; hence we may conclude that the climate of the northern extremity of the United States is too mild for its constitution.

The American Larch has a slight, straight trunk, about 80 or 100 feet high, and 2 or 3 feet in diameter. The wood is superior to that of any species of Pine or Spruce, and unites all the properties which distinguish the European species, being exceedingly strong and singularly durable. In Canada it is considered as

being among the most valuable of timber, and has no fault except its weight. In the district of Maine it is more esteemed than any other timber for the knees of vessels, and is always used for this purpose when proper pieces can be procured. Turpentine is never extracted from it in America, as is done from the American species in Europe, but not in Great Britain, as it ruins the timber. Venice turpentine is the article obtained from it.

The European Larch.—In Great Britain the Larch, formerly unknown, has been very extensively planted within the last century, the first plantations being made on the estates of the Duke of Athol, at Dunkeld. The lower ranges of the Grampian Hills, which extend to Dunkeld, are at an altitude there of from 1,000 to 1,700 feet above the level of the sea. The Larch trees are planted as high as 1,200 feet up these hills, and grow exceedingly well, a situation where the hardy Scotch Firs cannot rear their heads. The growth is very rapid, and Fir of the same age gives only half the quantity of wood. In the Larch plantations of this country we have several varieties of the tree, some having white flowers, or female catkins, and some having red; and we generally find trees with their flowers and timber of all shades between white and red. These differences in the colour of the flower and wood being no doubt caused by some accidental circumstances of soil or impregnation. Dr. James Brown observes of this tree—"As to the durability of the timber of the Larch, it is allowed, by all who have had occasion to use the timber, to be decidedly the toughest and most lasting of all the Coniferous tribe we are yet acquainted with." There is also a peculiar feature characterising the wood, viz., its being durable and tough when only of a few years' growth. A Larch paling, put up with wood from fifteen to thirty years old, lasts from fifteen to twenty years; if of Scotch Pine, of the same age, from four to six years; and if of Spruce Fir, from seven to nine years. If Larch posts are used, they will last from eight to ten years in a fair state; if of Spruce Fir, from four to five years; and if of Scotch Pine, from three to four years. Its durability makes it much sought after for mining purposes, and for this purpose large quantities of it are annually used. For the purpose of sleepers there is an unlimited demand, this sort of wood being always preferred for that purpose where it can be had, as it is found to last longer than any other kind when laid on the earth. It is difficult to season, as it is almost impossible to keep it from bending and twisting, and Mackintosh mentions steaming as one resort for overcoming this tendency. Some steep it, while in the log, in water for twelve months, then take it out and dry it twelve months more before cutting up. Others prefer the practice of barking the tree while standing, and then leaving it a year before it is cut down. The Athole, frigate, built of it in 1818, the Larch, a fine brig, built by the Duke of Athole several years earlier, and many others built since these dates, have, according to the "Builder's Reporter," proved the Larch to be as valuable a timber for naval purposes as its most sanguine advocates could desire. The wood, containing an insoluble varnish, preserves iron nails driven into it from rust, and after a lapse of twenty-three years they have been found to be as perfect as when they first came from the forge. One of the qualities of the Larch for building merchant ships is its great lightness, a cubic foot weighing, when seasoned, only 34 lb.; although it is not so strong as many sorts of wood, it has great resilience. Cabinet-work of great beauty has been made from it; it polishes well, and when well seasoned is not found to warp or shrink. A most important fact, as regards rural economy, has arisen from planting Larch trees on rocky ground. The vegetable compost found thereon by the falling of the leaves has been the cause of producing herbage for feeding, and making the land worth 12s. to 14s. per annum, which was not formerly worth more than 8d. or 9d. The tree is not particular as to soil, but the roots must be in a soil deep and porous, which has been cleansed by the free passage of water through it, and which has, at the same time, the benefit of being constantly kept clean and in a wholesome state by good descent for the water that may fall upon it. It does not thrive on thin lands, nor on those having a retentive sub-soil. Much of the disease in our Larch plantations, (says Dr. Brown) has been occasioned by imperfect drainage. The common Larch is a native of a great part of Central Europe, and forms forests in the upper regions of the Alps of France and Switzerland, from east to west, at elevations of from 3,000 to 6,000 feet above the sea-level; and when found above the latter height it is but a dwarf scrubby bush. It is less common on the northern than on the southern slopes of the Alps. It is found on the Carpathian Mountains, and in the Tyrol and Hungary.

Mr. Meehan on New Conifers and their Synonyms.—There is a disposition among botanists to make numerous species of our American Coniferæ. Mr. Hoopes did good service in his "Book" by throwing many of these novelties back to their proper places.

There will be plenty more work for him in a new edition. *Pinus Jeffreyi* may go back to *P. ponderosa*, and so on of many others. Then we have *Picea bifolia* and *P. magnifica* of Murray, and *P. violacea* of Roetz, which will probably have to go back to *P. grandis* as *P. amabilis*, *P. lasiocarpa*, and *P. Parsoniana* have had to do, and we should be inclined to put *P. concolor* among these probabilities, only that we have more faith in Dr. Engelmann's powers of discrimination than in some others, though, of course, the best of botanists may be mistaken. That all these may be distinct forms well worthy of separate propagation, as we separate Tom Thumb, George Peabody or other Arbor-vitæ in cultivation, is well enough, but no one wants to burthen botany with specific names for these. Another matter we may refer to here, is that the English papers speak of *Picea concolor*, Engelmann, but there is no such plant. It is *Abies concolor*, Engelmann. It should be explained that originally the genus we now call *Abies*, was *Picea*; and the *Picea*, *Abies*. Most horticulturists, chiefly, we think, through the great influence of Loudon, follow the change. Botany, however, is strict on the laws of priority, and if right in one case, it should be in all. Dr. Engelmann is always strenuous in behalf of right, and hence calls the Firs *Abies*, and not *Picea*, and the Spruces *Picea*, and not *Abies*. We know that Mr. Hoopes, equally with ourselves, knowing that Dr. Engelmann is right, and that right should prevail, has been always disposed to "call things by their right names." But the error is so widely diffused, and maintained by the whole force of English horticultural literature, that we have shrunk from the confusion that would follow an attempt to enforce the rule.—"Gardeners' Monthly."

New Variegated Plane.—Some time since, Professor Karl Koch called attention, says the "Florist," to a new variegated Plane (*Platanus orientalis Rosenthalii*) which he had seen in Mr. Rosenthal's nursery in Vienna. "True," he says, "we have had a variegated Plane in cultivation for some year, but it is far inferior in point of beauty to the one in question, being of a permanently shrubby habit, and possibly belonging to *Platanus cuneata*, Willd., a species I found on my second trip to the Caucasus in 1844, growing on the banks of rivers and rivulets on the south-eastern slopes. The unequally five-lobed leaves, too, remain small, barely attaining 4 inches in length; and the variegation consists of yellowish-white patches or stains, most abundant near the circumference. Of Rosenthal's variegated Plane, which is a variety of the Oriental, only small, shrubby specimens were seen, but should it prove to retain its variegation in the adult stage, we have here one of the most beautiful ornamental trees imaginable. It has ample leaves, usually somewhat broader than long, its broadest diameter reaching about 10 inches, whilst from the top of the petiole to the opposite extremity of the blade it is only about 7 inches; it has an abrupt base, each half of the blade forming a right angle with the petiole. The agreeably conspicuous yellowish-white markings cover by far the greater portion of the surface; but the white is interspersed with green streaks."

NOTES AND QUESTIONS ON TREES AND SHRUBS.

The Large-flowered Jasmine (*Jasminum grandiflorum*).—This Jasmine is well worth adding to the most select list of greenhouse climbers. It is a native of the East Indies, and naturalised, according to Vol. II. of the "Botanical Register" (where it is figured at p. 91), in the Island of Tobago, where it forms an undergrowth in the woods. It is largely cultivated in Catalonia, especially near Barcelona, and "oil" of Jasmine is there largely made from its flowers, while the peculiar long pipe-stems, so highly prized by the rich Moors, are made from its slender stems. It has been grown in this country since 1629, and used formerly to be imported along with Orange trees by the Italian nurserymen. It does best grafted on the common Jasmine and on *Jasminum officinalis* as a stock.—B.

Deutzias from Seed.—How many varieties of *Deutzia* are there in cultivation? I find the following in books, viz.:—*D. canescens*, *D. corymbosa*, *D. staminea*, and the old *D. scabra*; there are also *D. crenata* fl. pl. and *D. gracilis*. Where are the three former to be seen? To show how easily they may be increased, I may state that I raised a batch of seedlings a few years back, and among them is a pretty single pink kind and a very good double white. There are others, too, somewhat similar to *D. crenata* fl. pl., which was the parent of all of them. I could never get seeds from *D. gracilis*; but a double variety or a pink variety of the habit of *D. gracilis* would be an acquisition.—H. M., *Engs.*

New Timber Country.—A new timber-producing district is said to have been discovered in the interior of Newfoundland, a region hitherto supposed to be utterly barren. Amongst its naked mountain ridges and dreary swamps, Mr. A. Murray, an officer of the Geological Survey Office at St. John's, has come recently, according to a correspondent of a contemporary interested in colonial affairs, upon a rich country, which is expected to develop immediately a prosperous lumber trade, and, ultimately, to attract agricultural settlers.

Chestnut Trees.—Some years since—probably a good many—we are informed, there stood at Fortworth, in Gloucestershire, a Chestnut tree said to be 1,100 years old. The same tree was standing in 1150, when it was called "the great Chestnut of Fortworth." It measured 52 feet round.

Plants in Schools.—Dr. W. Kuby has published a treatise on the hygiene of schools. He recommends the introduction of leafy plants and shrubs at suitable intervals into every schoolroom, and attests the utility of the arrangement from experience.—"Lancet."

GARDENING FOR THE WEEK.

Roses Out and Indoors.

THE winter having been severe for out-door Roses, it is advisable to uncover now where this has not already been done, and to examine all beds and plantations so as to fill up vacant places before the season gets too far advanced. In some parts, where operations have been retarded by snow and heavy rains, a great deal of planting has yet to be done. If a vacancy occurs after this time, it must be filled by means of plants turned out of pots. I have found March to be the best month to go through all Roses, and to prune, tie, train, and stake them; but where great neatness is insisted on, Roses should be shortened back in December, when fallen leaves, &c., are being cleared up. Doing this does not hurt the plants, and it gives them a more uniform appearance than they otherwise would have. Where there is a large collection, and a continuous supply of Roses is wanted, good blooms may be obtained about the end of May or beginning of June, and, by carefully removing all dead flower-stalks every week, a continuous supply may be kept up all through the season. In pruning, care must be taken to thin out the bush, and to leave room for young shoots, so as not to have them overcrowded. Where Roses are wanted to form weeping or umbrella trees, cut all the shoots to equal lengths, and, where wire is not used, train all down with string to a centre stake; by so doing handsome specimens may be obtained. There are many varieties that are much weaker growers than others, and these require close pruning. Almost all Hybrid Perpetuals, Teas, and Bourbons succeed well pruned back to three or four buds; but Noisettes and Chinas do not require quite such close pruning. In the case of pot Roses, for forcing early for Christmas and New Year's Day, certain plants must certainly be sacrificed in order that perfect specimens may be obtained at that season. Charles Lefebvre will flower at that time, and I have cut *Devoniensis* and *Maréchal Niel* as fine at Christmas as in March. Good forcing varieties of Roses are now almost countless, but I always maintain that the selection of kinds for that purpose is best left to growers themselves, that is where a quantity is required. There are, however, many kinds which it is useless to grow, if blooms have to be packed or sent away. At one time we had only a few varieties that would force well, such as *Sidonia*, *Madame Laffay*, *Duchess of Sutherland*, and *Geant des Batailles*; but now we have a splendid assortment of new Roses that will force, and I hope to see the time when Rose blooms will be as plentiful as those of *Camellias* in the dead of winter. Roses, to bloom in March, will come in, even under greenhouse treatment. I do not think that plants for forcing should be fresh lifted every season; on the contrary, I have plants that have been in the same pots for ten years, and which never have had fresh soil applied to them.—H. G.

Hardy Flowers, Alpine Plants, and the Wild Garden.

During the first or second week in March there should be an overhaul of seeds to be sown. Some, of course, have been saved during the previous summer, others purchased, and possibly not a few may have been picked up in an autumnal tour of inspection. Be the source, however, what it may, it is now high time that they were looked over, and in due course sown, as my experience with seeds, more especially of our hardier plants, is that an early sowing very often saves a season. No one who has had much experience in seed sowing can have failed to notice how tardy and irregular the growth of autumnal-sown seeds is compared with those sown in spring; nor, indeed, is this surprising, as the gradually-increasing power of the sun's rays, charged with active influence, is not only conducive to the development of seed life, but is felt, and that, too, in a very pronounced way, by Man himself—the most highly-developed form of animal organisation—and may be traced through the whole series of gradation in organic life. Truly do we recognise the spring as essentially the seed time—antipodal to harvest; does not the embryo, as it springs from its hibernatory store-house—the seed—give us, to some extent, the origin of the word spring, one of the most gladsome words in our whole vocabulary? A few remarks, therefore, as to the mode and process of sowing the seeds of such plants as come under our especial heading may not be out of place. Herbaceous and Alpine plants in this operation must be treated quite distinctly from the ordinary annuals and biennials, about which I shall have a word or two to say by-and-bye. For the present I confine myself to the former. Though in very exceptional instances, as regards the plants themselves, and in equally exceptional conditions of soil and situation, it may be advisable to sow them in the open ground. As a general rule they are better sown in pots or pans and placed in a cold frame, where they will receive protection from heavy showers that not unfrequently denude the seeds of their covering-protection; under these conditions, too, they are readily amenable to the

process of shading from the drying influence of the sun, and are safely removed from the possibility of spring frosts and east winds. Independently, moreover, of the foregoing reasons for adopting the media of pots and a cold frame as best adapted for this purpose, there are others, the most important being that this arrangement enables you to remove those pots, wherein the seeds are endowed with natural powers of early vegetation, to another frame, where they may enjoy a greater degree of sunshine and consequent vigour, combined with sturdiness of growth—without exposing those which have not grown to similar conditions, which, in their case, would be prejudicial. Then, again, amongst plants of this class, the size of the seeds varies so considerably that, whereas one may vegetate freely under the depth of half-an-inch of soil, another must be sown almost on the surface. Thus individualising the species enables the operator to deal with each, according to its special requirements. In preparing the seed-pots, as in every horticultural and agricultural operation, a thorough and efficient drainage, by means of crocks to rough ashes, is a necessity. It acts in two ways; first, by preventing the soil in which the seeds are sown from becoming water-logged; secondly, by admitting from below, as well as from above, a free supply of atmospheric air, which has a most important chemical function to perform in stimulating the dormant energies of the seed into active life. The next point is to secure a good loamy soil of somewhat sandy texture, and, if possible, a little well-rotted leaf-soil combined therewith in a proportion of about one to three—the whole passed through a medium-meshed riddle—the rough material to be placed over the crocks, so as to prevent the drainage getting choked up; the fine portion to be filled in above and well pressed down. Do not be afraid of making it firm, as seed rootlets, however tender they appear to be, have wonderful powers of penetration, and prefer a hard soil, which retains a more equable degree of moisture than a light one, which is liable to great fluctuations in this important respect. The pots being filled to within half an inch of their surface may then be sown, but, before doing so, a little soil passed through a fine riddle, and well mixed with good sharp sand (silver sand is preferable, as it takes the water readily), should be prepared, and used for the purpose of covering the seeds. As to the thickness of this covering, a very safe rule to follow is, that it should equal the diameter of the seeds—that is, when the seeds are sown under the conditions herein described. Prior to the seed pots being placed in the cold frame, it will be well to give it a good dressing of fresh slaked lime and soot mixed, so as to destroy slugs and worms, both of which are highly prejudicial to the success of the operation. Above this dressing nothing is better than a layer of 2 or 3 inches of ashes, and care should be specially taken to place the pots level, so that the seeds may vegetate freely over the entire surface at one and the same time. If the soil be reasonably damp no water need be given for a week or ten days, but the frame must be shut up and shaded, after which a gentle sprinkle with tepid water, with a fine rose, will be found beneficial; and, as a rule, as the season advances, it is better to throw the lights off the first thing in the morning, and give them water about eight o'clock, by which exposure the pots that are really dry will have indicated themselves, and thus the watering operation, too apt to become general, will be confined to those pots alone that require it.—JAS. C. NIVEN.

Flower Garden and Pleasure Grounds.

Where the planting of deciduous trees and shrubs, and the laying of Box and other edgings, have been delayed in consequence of the severity of the weather, these operations should now be brought to a close as soon as possible. On light soils, under the shade and drip of trees, and in other unfavourable situations where "living edgings" seldom succeed well, an edging-tile of some sort should be used. These can always be had of various patterns, and may consist of common brick, terra cotta, terra metallic ware, glazed stone ware, and of glass. Some, composed of the latter material, are of a green colour, and remarkably neat in appearance, and well adapted as edgings for flower beds and borders. Hollies, Laurels, and all other evergreen shrubs and trees may now be pruned wherever they are found to need that attention. It is seldom advisable to compel shrubs and trees to assume forms different from those which are natural to them; but they may, nevertheless, be frequently assisted in this matter by the stopping of unduly developed lateral branches or rival leaders. While strong growing species should be prevented from unduly encroaching upon less robust, but choicer sorts. Young Coniferous trees of all kinds may frequently be greatly benefited by the judicious stopping of lateral branches, so as to direct the energies of the plants towards the development of the stems or leading shoots. Hollyhocks may now be planted out, as may also Pinks, Carnations, Picotees, and Pansies, and all beds or clumps of these and similar plants, which may have been planted out last autumn, should now be carefully examined, as many of them

may be found to be somewhat loosened in the soil, by the action of the recent frosts, and should now be made secure; the surface of the beds too should be refreshed by a portion of new soil, and all deficiencies, where they exist, should be made good. Annual flowers of all sorts, if required to flower early, may now be sown in gentle warmth, in pots or seed-pans, to be pricked out, when large enough to handle, into boxes or frames, so as to be ready to be planted out early in May, in beds or borders, in which they are intended to flower; or, should the weather be favourable, they may be sown at once in the open ground; during most seasons, however, the first week of April is sufficiently early to do this. In cases where it may be intended to edge or margin the flower beds with any of the dwarf hardy Alpine, or other plants suitable for that purpose, this may be done now, should the beds be empty, or should it be found possible to do this without injury to the spring flowering plants and bulbs which they may contain. Many of the latter, such as Pansies, *Violas Forget-me-nots*, *Aubrietias*, *Hyacinths*, bedding *Tulips*, &c., will now be coming into flower; the marginal plants that may be planted now may consist of such species as the variegated *Ajuga reptans*, *Arabis albida*, *Antennaria tomentosa*, *Achyrocline Sandersoni*, *Centaurea ragusina compacta*, the variegated *Dactylis glomerata*, *Gnaphalium tomentosum*, *Stachys lanata*, *Santolina incana*, *Veronica incana*, *Cerastium tomentosum*, *Polemonium coeruleum variegatum*, and others of a similar kind, all of which are quite hardy; and, if planted out now or before long, will be well established by the time the summer bedding plants are planted out. Many plants which are not considered sufficiently hardy to withstand the rigours of some of our winters, and which may, as a precaution, have had some slight protection accorded them, should, in most cases, have such coverings removed now, or the young growth will be likely to become blanched and attenuated. Continue to increase the stock of bedding plants of all kinds, and pot off singly the various sorts of bedding *Pelargoniums*. If pots are scarce or accommodation limited, some of the more free-growing green-leaved kinds may be taken out of their pots or store pans, and have their roots wrapped separately in Moss, in which is enclosed a little light rich turfy soil. The Moss should be tied loosely round with a piece of worsted or shred of bast, and the plants should be plunged in a bed of light sandy soil or leaf mould in a cold pit or frame, but not too closely together; then give them one good watering, and keep the structure close for a few days or until the roots are found to have laid hold of the Moss, which they will readily do; when that is the case they should have abundance of air and water, as may be required; and at planting-out time they may be moved into the beds with good balls of earth adhering to them. Plants thus treated will be found to succeed quite as well as those turned out of pots. *Calceolarias*, *Verbenas*, and other bedding plants may be treated in the same manner, only in their case the Moss may be dispensed with.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Indoor Fruit Department.

Vines should now be planted, for the operation must not be delayed until the buds are breaking, or a check will be given to the tender growth, and to avoid this, every care should be taken. The young canes should be the best that can be obtained of last season's growth, and they should be turned out of their pots on the spot in which they are to be planted. The soil should be nearly all shaken from the roots, and every coiled fibre must be laid straight, so as to run away from the base of the stem instead of encircling it as they do while in the pot, and any long roots that are wanting in fibre may be cut half-way back. When the roots are set in the border they should be thrown out in all directions, but where the border is only one-sided the greater part of the roots should be set in the direction from which their support is drawn. An inch or two of the finest soil should cover the roots, as the round lumps do not fit in about the small rootlets well, nor are they so easily penetrated. Where it is desired that the roots should all remain in the outside border the Vines must be planted entirely outside, close to the ground level of the front sashes, where a round hole, a few inches in diameter, must be made opposite every Vine to let the cane through into the inside. I am in favour of having a border both inside and outside, and of planting the Vines inside and letting the roots go out, if they will, by archways along the foundations of the house. Whether inside or out, the roots should be watered after they are covered with soil with water at a temperature of 90°. Those planted inside need no immediate attention after this; but, when planted outside, the ground for a radius of 3 feet round the plants should be mulched with about a foot of rough stable litter. This, in case of cold weather, keeps the soil in a comfortable state, but it must be removed before it affects the roots by drawing them. The distance between each Vine must be regulated by the manner in which it is intended to train the rods when they grow up. Where a modification of the extension system is to be followed, and two or three rods from

each root are taken, the plants should be from 5 to 6 feet apart; but, where only a single rod has to be taken from each root, 2½ feet is quite sufficient. More plants are required to plant a house on the restricted than on the extension system; but, where young Vines are planted at the widest distance apart, an intermediate one should be planted between each. This latter subject should be a fruiting cane, one which would fruit as a pot Vine if kept in the pot throughout the summer, as it will do if planted out, so that a crop of fruit may easily be obtained in the "young Vinery" the same season as planted. A span-roofed Vinery, with a full inside border and an outside one only at one side, as circumstances sometimes necessitate, should have the one-half of the Vines planted outside to derive their nourishment exclusively from the outside border, and the other half should be planted inside, so that the chances of subsistence may be equally divided. The generality of canes, which are from 4 to 6 feet in length, should have all outside buds rubbed off, retaining four inside, to which the canes should be cut back, and the wound plastered over with a styptic; the four buds left will soon break freely. Another method which may be practised by those who may be afraid to risk the chance of growth with four buds, is not to cut any from the top, but allow all the buds to break and grow for an inch or so, and rub the small growths off from the point downwards until the desired number is reached, when the budless top may be cut off as soon as there is a strong current of sap flowing up the growing shoots.

Pines.—Old roots and stems of valuable shy-producing sucker sorts, of which the smooth Cayenne and Charlotte Rothschilds are types, which may be lying about after the general shift, should not be thrown away. When placed in cutting boxes or pans, and covered over with loam, many of the eyes burst, and grow into fine suckers, if started in a bottom-heat of 90°. All the leaves require clearing from the stem before laying them in, and the root may be cut off also. Sometimes the suckers may be so small as not to be fit for removing them from the stem. In this case, the leaves should be cut back to within 3 inches of the stem, without disturbing the sucker; and lay them closely together by the root, where the assistance of a bottom-heat of 80° can be given to perfect the young sucker. The corner of a bed does well for this purpose, providing there is a quantity of soil about the roots before pressing the plunging material around them. Should strong sunshine prevail at any time, for three weeks after plants have been re-potted, a slight shading with thin canvas will be of much benefit to them.—J. MUIR.

Hardy Fruit.

Owing to the severe weather which we have had, work in this department has been nearly or quite at a standstill for some time past; those, therefore, who advocate early pruning and planting, have decidedly the best of the argument this season. Finish as soon as possible all pruning, nailing, and tying, and now that the buds are so forward extra care will be required to prevent them from being injured. I would again advise that protection of some kind or other be applied to all trees requiring it forthwith. The spring season is always so changeable and uncertain that it is never safe to dispense with it. The "scrim canvas," which we use here for covering, is—next to glass—the best possible material that can be employed as a protector, as it is thick enough to resist several degrees of frost, and yet so open as to allow sufficient air and light to pass through it to the trees, should the weather necessitate the coverings remaining down for several days together. As a proof of its protecting powers, I may mention, that on the 12th of March last year, when our Apricots were in full bloom, the thermometer registered 16° of frost, and, though this was the only covering they had, they were quite safe. The blinds should always be drawn down during bright sunshine till the bloom opens, and even then during the prevalence of keen "north-easters" and snow or rain. Autumn-planted Strawberry beds should be looked over, and such plants as have been upraised by frost should be made firm. Now is a good time to plant out from the reserve stock pricked out in autumn, and where forcing the Strawberry is carried out—as it is in most places—the best and earliest runners may be had from this plantation. Any flowers that make their appearance should be at once removed, in order to induce a greater profusion of runners for early layering. As to kinds, every gardener has his favourites; and mine are as follows, viz.:—President, Keen's Seedling, Vicomtesse Héricart de Thury, John Powell, Lucas, Sir Joseph Paxton, British Queen, and Frogmore late Pine. The merits of these are in accordance with the order in which the names stand. For forcing, the best are President, Vicomtesse Héricart de Thury, and British Queen, and, taking all points into consideration, President is the best Strawberry that can be grown. Figs that have been protected through the winter may now be uncovered, taking care to have means of protection at hand if needed. The winter covering of these is, upon the whole, a somewhat questionable proceeding, as it must have a tendency to make the trees more tender than they otherwise would be if left constantly exposed, or

treated the same as Apricots or Peaches. Amongst hardy fruit few are more generally useful than the Gooseberry, and yet, how often are Gooseberry quarters neglected, and left to take care of themselves, a circumstance arising, I apprehend, from the notion (which, to a certain extent, is correct) that they will grow without attention; but, though they will do this, they will also give good returns for proper attention in the way of pruning, thinning of branches, clearing of suckers, and manuring; on frosty nights, when in flower, they are easily and effectually protected by shaking dry hay over the bushes. Never mind the litter and unsightliness so long as the fruit is safe, as it will be under such protection. Currant bushes may be covered in the same way, and with like results. Filberts, and Nuts of all kinds require but little or no pruning. We have a fine row of various kinds here, and all the attention they require is to keep them free from suckers, and the main branches from chafing one another; where that is the case, cut out at once all such branches.—W. WILDSMITH, *Heckfield*.

Kitchen Garden.

In some gardens, the larvæ of the Carrot fly is so destructive as to render the crop almost useless, especially for late-keeping purposes. Many remedies have been recommended, all perhaps more or less beneficial; but their ravages are still seriously felt in a very great many places. In some gardens, it has been found necessary to sow the Carrots on specially prepared beds, which are formed by taking out the original soil to a considerable depth, and filling in with compost consisting of thoroughly decayed leaf mould, burnt earth, &c. Where this plan cannot be adopted, I should recommend the following system of culture to be tried. Select a dry day when the surface of the ground works easily and cleanly; mark out, in a dry open part of the garden, a piece of ground of sufficient size, that has been turned up roughly during the winter. Scatter evenly over the surface $1\frac{1}{2}$ bushels of air-slaked lime, 1 bushel of fresh soot, and about 15 lbs. of common salt, per square rod of land; fork in, and, in doing so, endeavour to mix it with the soil as thoroughly as possible; and then leave the land to settle till the first or second week in April, when the ground may be rolled or trod down, and the seeds drilled in. When the plants are up and thinned out, a further, but much weaker, dressing of soot and salt may be placed on the land in showery weather, if the crops have been previously much infested; and during the growth of the crops all red or rusty-foliaged plants should be pulled out as they are sure to be attacked. In the autumn, when the crop is lifted, the same plot of land should be manured and trenched, burying the manure 18 inches deep, and turning the land up roughly. During frosty weather, when the surface is hard frozen, it should be well broken up with a pick, so as to let the frost well into it. In the month of March following, dress it again with soot, lime, and salt, in about the same proportions as formerly; and, in the autumn, manure and trench deeply again. If this treatment be persistently carried out, the same plot of land will produce good crops of Carrots for several years, when a fresh piece may be prepared in a similar way. After the first two years the dressings of salt and lime may be reduced in quantity, but Carrots will take up a good deal of those substances with benefit. The manure that is buried deeply at the first trenching is brought up to the surface at the second—or at least what remains of it; and, when mellowed by the atmosphere, is in good condition for the crop. During the past month the weather has been very unfavourable for performing the usual routine work; but now, as we shall probably have a period of genial weather, every effort should be made to make up for lost time. If it has not been done, Parsnips and Onions should be sown at once. Sow Radishes once a fortnight; Lettuce about every three weeks. A good rule to adopt with Peas is to sow again as soon as the preceding crop is through the ground. Small sowings of round Spinach may be made once a fortnight, and a small sowing of the New Zealand Spinach may be made in heat for transplanting when suitable. Walcheren and Veitch's Giant Cauliflowers should be sown on a warm border, to come into use in August. A full sowing of Leeks for transplanting for main crops should now be made. Autumn-sown Cabbages should be planted out, and a sowing made of Cocoa-nut, Enfield Market, and Atkins' Matchless. The planting of Cauliflowers under hand-lights or other protectors may be completed, but those plants intended for the open ground may remain where they can have protection till the beginning of April. All vegetables sown in heat under glass must be pricked off before they become weakened by overcrowding. Cauliflowers, Lettuces, Celery, Tomatoes, Capsicums, &c., must have attention to bring them forward and properly harden them off for planting at their proper seasons. Whenever the surface is dry use the hoe freely amongst growing crops; draw a little more soil to early Cabbages; finish making new plantations of Horseradish and Jerusalem Artichokes, and see that Box or other live edgings are free from weeds, as they will soon grow and, in the case of Grasses, soon seed.—E. HORDAY.

ROYAL HORTICULTURAL SOCIETY.

THE adjourned annual general meeting of this Society was held on Tuesday last, under the presidency of Lord Bury. An amended report was submitted from the Council, which stated that since the first report had been drawn up the position of the Society's affairs had materially changed. The speech made on behalf of the Royal Commissioners at the last meeting was so favourable in character, and conveyed utterances so satisfactory to the Society, that the Council felt it incumbent upon them to omit from the report any passages which might present even the appearance of disunion between themselves and the Commissioners in question. The chairman detailed what occurred at the last meeting, and which led to the withdrawal of the report then presented. He also read a letter from the Commissioners, dated the 8th of March, and signed by Major-General Scott, stating that the Commissioners were perfectly satisfied as to the legal position and status of the present Council, and were willing to open friendly relations with the Society. The chairman then commented upon the horticultural position of the Society, which he considered eminently satisfactory. He believed that the Society could get out of its liabilities if the Fellows would agree with the following recommendations of the appended report:—"The attention of the Fellows is specially called to that fact that, unless the rent of £2,400 is paid to her Majesty's Commissioners next year, the lease of the South Kensington Gardens may be forfeited, and, to prevent this contingency, an increased revenue must be obtained. This increased revenue, the Council suggest, may be obtained by concerted action on the part of the Fellows, whether resident in the neighbourhood or not, and by increasing the number of Fellows. The Council are prepared to invite a general meeting of the Fellows to discuss this question in detail. A definite scheme will then be submitted for consideration. The Council beg to express their unanimous opinion that it is the bounden duty of the Society to do its utmost to retain the Gardens in its possession, as 'a suitable area in which they may exhibit and display the progress of horticulture,' and also to enable them to fulfil the Society's obligations to their life Fellows and their debenture-holders; and, in such a course, the Council feel sure they will have the hearty and cordial co-operation of every Fellow of the Society." He concluded by moving the adoption of the report. Mr. Guedalla said the income last year showed a deficiency of £2,400; and that amount, he thought, could be wiped off by a ball under distinguished patronage. He advocated the retention of the skating rink as a source of income. The Rev. C. P. Peach moved an amendment to the report, that the meeting be adjourned in order that the report be referred back to the Council, so as to enable them to prepare a scheme of arrangement with her Majesty's Commissioners, and to report the same to an adjourned meeting. Mr. Quilter seconded the amendment. The Chairman said the Council would look upon the amendment as a vote of want of confidence, as he believed that, if the report was refused, the Society would be on the high road to ruin. The Council were ready to name a day for the discussion of the terms of an arrangement with the Commissioners. After considerable discussion the amendment was withdrawn, and the report was adopted unanimously. Mr. Horton then moved that the meeting be adjourned for six weeks to receive a statement from the Council on the subject of a scheme of arrangement with the Commissioners. Dr. Masters seconded the motion, and on a show of hands it was negatived by a considerable majority.

THE FUTURE OF THE ROYAL HORTICULTURAL SOCIETY.

I OBSERVE, in your last week's issue, a letter in which Mr. Wilson sets forth his pet crotchet about "guinea Fellows," and seems to think that, if his scheme is carried out, a large number of gardeners in the country will subscribe a guinea each. I feel pretty sure that Mr. Wilson's prediction would never be realised, even should his scheme be adopted, inasmuch as there are very few gardeners who have guineas to spare. If Mr. Wilson will examine the subscription list of the Gardeners' Royal Benevolent Institution, he will see how many gardeners there are who subscribe to that truly excellent institution; and it does seem to me a lamentable thing that so few of the craft subscribe to an institution from which, should misfortune unhappily overtake them, they would derive substantial benefit. But what I wish to refer to more particularly is Mr. Wilson's allusion to Manchester as a "test place" for the adoption of his scheme. I presume he means that the pulse of the Manchester people should be felt to see how many guineas they are disposed to give to the Royal Horticultural Society. Is Mr. Wilson ignorant of the fact that there exists a society in Manchester, called the Botanical and Horticultural, who distribute annually, at one exhibition, about £1,000 in prizes, and whose programme for the present year embraces the following:

—Floral meetings at the Town Hall, on the 16th March and 27th April; national horticultural exhibition, in May; exhibition of American plants, in June; show of Roses and floral table decorations, in July; exhibition of Carnations, Picotees, and new plants, in August; and an autumnal exhibition of fruits, vegetables, and flowers, in September? It seems to me that Manchester would be a most unfortunate test place. The Royal Horticultural Society paid a visit to it in the year 1869, and, owing to the indiscretion of those who had the management of the affair, cut a very sorry figure. I hope, however, that something may yet be done to make the Royal Horticultural Society a national institution.

A. B.

KEW AND SIR JOSEPH BANKS.

A TRUER figure than Mr. Elwes' would be that the "letter" to which he refers was "a stone put in to stay the fall of the botanical department at the British Museum." No one would feel more pleasure than myself in the achievements at our grand national *hortus vivus* at Kew, if the experiments on living plants supporting the actual status of botanical physiology, and its practical results, had been there carried on. To divert from the national *hortus siccus* at Bloomsbury its proper supplies seems a poor substitute of action. The idea of a national collection of living plants within easy reach of London, and of a national herbarium within the metropolis, with their respective and distinct applications, will commend itself to the political economist appreciating the advantage of "division of labour." The realisation of the idea, to the extent to which he was enabled to effect it, adds honour to the name and memory of Joseph Banks. Idle gossip, possibly scandal, about bye-gone times at Kew, bears no relation to the actual crisis; but may be safely indulged in now that the great ones assailed have passed away far beyond and above it.

RICHARD OWEN.

Mr. Elwes has sent you (p. 208) a quotation from Dean Herbert's "Amaryllidaceæ," containing a violent attack on Kew in Sir Joseph Banks's time; but, in justice both to the Dean and to Kew, he should have further quoted the remarks in the Appendix, p. 410, "I observe that I have incautiously admitted a stronger expression concerning the unpopularity of the principle on which those gardens have been conducted than I should wish to have used." I am glad to read Mr. Elwes' vigorous championship of the present management of Kew, and I thoroughly endorse all that he has said. I believe I speak with a longer experience than Mr. Elwes, and I can say that nothing can exceed the liberality of the present management, either in the distribution of plants or in giving information and advice.

Bitton Vicarage.

HENRY N. ELLACOMBE.

Mr. Elwes seems to think that all plant collectors should send their duplicates to Kew; but why, let me ask, does not Kew send out collectors herself, and thus help us in searching out the hidden riches of Flora in different parts of the world? At present, as much money is spent every year on the "bedding out" system as would pay the expenses of a good botanical collector. Is it that the unknown plants of the world are not worth seeking for, or, is it more important to please the many by making the garden easily understood by those who have a fancy for showy patterns?

J. CROUCHER.

Sunken Boilers.—Your correspondent "A. D." (p. 212) will, I think, make a great mistake if he tries a boiler above the level of the flow-pipe for heating several houses upon different levels. It has often been asserted that such an arrangement would work satisfactorily, but I have not met with a single instance in which it did so, even at the cost of severe firing. Mr. Williams (p. 188) speaks of one house, 140 feet long, being heated by a No. 3 tubular boiler; but this sized boiler, if properly set in the usual way, ought to easily heat 850, or even 1,000, feet of 4-inch pipe. Has he so much pipe in the one house, and does his experience extend only to the instance quoted? Again, may I ask Mr. Hobday (p. 188) if the pipes in the houses (query, how many?) to which he refers are on different levels, or only slightly deviating from a general level; can he speak positively to no extra consumption of fuel now the boiler is raised, and will he kindly say where the "other instances" are to be seen? If within twenty miles of London, I shall be happy to make a special journey to inspect them. This I do know, and assert (and I believe that all hot-water engineers of any experience will endorse the statement), that the lower the boiler is, the more rapid the circulation, and the less the fuel consumed—the two main objects in all good heating apparatuses. Are these, therefore, not worth the small cost of making a stokehole water-tight.—R. S. DUNBAR, *Thames Bank Iron Company.*

NOTES AND QUESTIONS—VARIOUS.

[Many notes and answers, obligingly sent us by correspondents, are unavoidably omitted this week from want of room.]

The Sweet Capsicum.—What is the fresh sweet Capsicum, known in Spain as Bichos, or Pimientos dulces? No doubt some correspondent of THE GARDEN will be able to tell me where I may procure seed of these.—J. B.

Scilla bifolia near London.—Messrs. Barr & Sugden have at present in full flower in their bulb grounds a very showy bed of this Squill. The fine mass of intense blue which it produces is strikingly beautiful, and as it is a Squill that will grow well in nearly all kinds of soil and situations it is a plant desirable, not only for garden cultivation, but also for naturalisation.

Disrooting Camellias.—Allow me to ask Mr. Gadd what he gains by cutting away the roots of Camellias, even such as "are as thick as one's arm," previous to planting out as he advises (see p. 198)? Does he imagine that Camellias which have been confined in tubs and pots have too many roots? and what, in the place of the roots thus removed, supports the young growth of the present season, shortly ready to start?—T. BAINES.

Lettuces through the Winter Without Glass.—I have forwarded for your inspection two Lettuces as samples of what we have been cutting daily all winter. The variety is the Black Seeded Brown Cos, which was sown on the 3rd of August last and afterwards planted on good land. They have withstood this trying winter, protected merely by Fern or Bracken. For salads they are here greatly preferred to Endive.—R. GILBERT, *Burghley.*

Oncidium Weltonii.—We have just seen an exceedingly fine spike of this Orchid cut from a plant grown by Mr. Copeland Capper, of Leyton. It contained five single flowers on its upper part, three upon a short branch below them, and three other branches with four flowers on each, constituting a bold, showy inflorescence of twenty blooms. It is probably the finest specimen of this Oncid that has yet been produced.

Destroying Slugs.—For this purpose no dressing is so effectual as lime. I dust the ground all over, as well as the plants, every three or four days if the weather is wet, or if dry once a week, and usually two or three dressings are sufficient to save most crops; but, should the depredations continue, I persevere in the lime-dustings, stirring the ground with a hoe previous to applying them. The lime should be quick, but reduced to a powder, as it will be after a few days' exposure in a shed.—P. S.

Water Cresses Without Water.—The late frosts have deprived us, for the present of these purifiers of the blood. Some years ago, the late Sir Joseph Paxton told me that he used to grow them at Chatsworth, under a north wall, upon which the rays of the sun never fell, and that in this way a certain supply might be depended upon in the worst winters. If some enterprising grower for the markets would take the hint, and prepare for next winter, he might make a good thing when frost makes Cresses grown in water flabby and uneatable.—W. T. P.

Grafting Hardy Azaleas.—When should I graft Ghent Azaleas, which is the best stock on which to put them, and how should I afterwards treat them?—A. J. [Dr. Woodman, of the Exeter Nursery, states that Azalea pontica is found to be the best stock on which to work Ghent Azaleas. They are usually grafted in the spring, splice grafting being employed for the purpose. After grafting they are plunged in cases in the propagating-house, where they receive the same treatment as is given to Rhododendrons. The freer and commoner sorts are usually layered in the open ground in the autumn.]

Tomatoes under Glass.—Tomatoes now-a-days have become a standard vegetable, but they require to be grown under glass, even in the sunny south, to yield profitable results. They may be sown in January, grown in pots or planted out in a back border of a Vinery, where I have known them to do well, and where they form a continuation to the earliest pot supply. Last season I saw good results obtained by leading the plants into a pit, from a border in front, the fruit, which were supported in the stage, swelled to a large size. Hathaway's Excelsior is much superior both in flavour and appearance to older varieties.—R. P. B.

How should American Cranberries be Grown?—Perhaps some of your correspondents could afford me some information respecting the best mode of growing American Cranberries. Having a considerable surface of very moist ground, sloping towards the south, without trees to shade it, but protected in some measure by a wood of Hazels, &c., I am induced to try the growth of Cranberries. The ground is kept moist by the overflow of three or four pools led through 2½-inch drain pipe, which could be branched in any direction if required. If large masses of rooty peat were placed contiguous to each other probably the plants would do very well, but I should be glad to have more correct information. The Cranberry is extensively grown in America, and is used as a part of almost every meal. Any hints on the above subject would be greatly appreciated.—E. W. COOKE, *Glen Andred, Sussex.*

Forcing Rhubarb.—Many have an idea that Rhubarb raised in the dark is much more delicate than when otherwise grown. So it is, but the delicacy is obtained at the expense of flavour. The idea is a fashionable one, that is all. A few years ago I put some roots of Rhubarb at forcing time into my Mushroom house, and some others into a bed in my propagating-house. This was grown in the light, was ready first, and was used. When that in the Mushroom-house was ready, I took it in; but, a day or two after, I was instructed to bring in the old sort, if there was any, because the last had not so much flavour. I now grow my forced Rhubarb in the light. I am quite aware that a slight covering in the open ground in the spring and summer increases the beauty of the appearance of Rhubarb, and perhaps then of its flavour, but in winter it is better exposed to the light.—N. H. P.

Coprosma Baueriana variegata.—Your correspondent, Mr. Muir, asserts (see p. 172) that this has a dwarf and somewhat creeping habit; but, according to my experience, it must be kept neatly pegged down, otherwise it presents a very straggling appearance. I have seen plants of it, when not stopped, grow as high as 6 or 7 feet; therefore I cannot see how a plant, naturally so tall, can be said to have a dwarf and somewhat creeping habit. Mr. Muir also asserts that it is difficult to propagate, and I must admit that it is so; but, by following the plan which he suggests, success will be almost certain to be the result. The question, however, is, have we room in our propagating beds (especially at this season of the year) to admit of that plan being carried out? I doubt it. A method which I find to answer well is, when selecting the cuttings, to take a good heel off the old wood along with them; then to fill the pots two-thirds full of crocks, on which should be put a little light rich compost and a layer of sand. The cutting should then be inserted, watered, and plunged in a brisk, moist bottom-heat, taking care to give them only a very slight sprinkle overhead until rooted, otherwise they will damp off.—J. SIMMONS, *Warwick.*

"This is an art

Which does mend nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

MR. GORDON'S PINETUM.*
